PREFACE

WITH the object of providing recognised formulæ for medicines which were not official in the British Empire, various supplements to pharmacopœias have been published from time to time, the most notable being Gray's Supplement, which first appeared in 1818, and was subsequently edited by Professor Redwood. More recent works have usefully supplemented the current pharmacopœia by giving particulars of medicinal articles which, although in constant demand, had ceased to receive pharmacopœial recognition. In addition, they have furnished much valuable information concerning the newer *materia medica*, consisting of substances and preparations which had not yet attained the status of approved and established remedies included in the pharmacopœia.

THE BRITISH PHARMACEUTICAL CODEX, 1907.

The need for a work published by the authority of some statutory body had long been recognised, and by a resolution formally adopted on November 4, 1903, the Council of the Pharmaceutical Society of Great Britain decided to produce such a book of reference for those engaged in the prescribing or dispensing of medicines.

Accordingly, the production of the British Pharmaceutical Codex, 1907, was entrusted to a committee consisting of Mr. Michael Carteighe (*Chairman*), Messrs. C. B. Allen, S. R. Atkins, J. F. Harrington, G. T. W. Newsholme, R. A. Robinson and J. Rymer Young. The labour of compiling the information and conducting investigations was deputed to a sub-committee consisting of Dr. W. E. Dixon, Professor H. G. Greenish, Messrs. E. White, W. F. Gulliver, F. W. Gamble and J. T. Humphrey (*Secretary*), with whom, in the earlier stages of the work, were associated Messrs. H. Wilson and W. Kirkby. The research work required for the solution of problems involved was performed partly in the Pharmaceutical Research Laboratory of the Pharmaceutical Society and a large proportion was undertaken privately by individual members of the Society.

The scope of the book was defined by describing it as an Imperial dispensatory for the use of medical practitioners and pharmacists, since it contained information respecting all drugs and medicines in common use throughout the British Empire. It included also the principal substances and preparations which were official in the Pharmacopœias of France, Germany and the United States, as well as those described in the British Pharmacopœia. The aim of the work was the provision of accurate information for prescribers and dispensers, special attention being given to the requirements of those practising in the British Dominions.

During the four years following the publication of the British Pharmaceutical Codex, 1907, the work was subjected to extensive criticism and discussion, and numerous suggestions and recommendations were submitted to the Pharmaceutical Society with the object of making the book more valuable as a work of reference.

THE BRITISH PHARMACEUTICAL CODEX, 1911.

In January, 1910, the Society's Publications Committee reported to the Council that the preliminary work for the revision of the Codex, which had been conducted by Mr. J. T. Humphrey, was completed. The revision was commenced forthwith by the Codex Revision Committee, consisting of Messrs. C. T. Allen, H. Finnemore, F. W. Gamble, F. Goldby, W. F. Gulliver and E. F. Harrison, with whom were associated Dr. W. E. Dixon, as consulting pharmacologist, and Mr. E. White, representing the Society's Council. Mr. W. J. Uglow Woolcock was appointed Secretary to the Committee and Miss D. M. Braithwaite was appointed to conduct laboratory work in practical pharmacy. Assistance was rendered by members of the Society and of the Society's Staff, and the second British Pharmaceutical Codex was published in October 1911.

The plan of the book was modified in certain respects, the more important changes being (1) the addition of brief descriptive notes on the preparations of each drug and chemical at the end of the respective monographs, (2) the relegation of the working formulæ for all B.P.C. preparations to a separate section of the book, and (3) the inclusion of a pharmacological and therapeutic index, in which all the medicaments were grouped in a single alphabetical list according to their pharmacological action, their general therapeutic use and their application in special ailments. Further, where drugs, chemicals and galenical preparations described in the Codex were official in the British Pharmacopœia or the Pharmacopœia of the United States of America, that fact was indicated.

The appearance of a new British Pharmacopœia in 1914 necessitated the production of a supplement to the 1911 Codex. That supplement was added in 1915. It included some new monographs, galenical formulæ, a series of formulæ for test solutions, and a list of alterations in the text which were necessary to make the book consistent with the new pharmacopœia. This supplement was prepared by the Pharmaceutical Society's Codex Revision Sub-Committee, consisting of Mr. E. White (*Chairman*), Dr. W. E. Dixon, Messrs. F. W. Gamble, W. F. Gulliver, E. F. Harrison, E. T. Neathercoat and H. S. Phillips (*Secretary*), assisted by Mr. J. T. Humphrey and Professors H. G. Greenish and H. L. Smith.

A second supplement, relating to surgical dressings, was added in 1922. It was prepared by the Pharmaceutical Society's Codex Revision Sub-Committee, consisting of Mr. E. White (*Chairman*), Messrs. E. T. Neathercoat, H. Skinner, and F. Browne (*Secretary*), assisted by Messrs. E. A. Andrews, T. Barclay, S. Crabtree,

R. Fouracre, A. D. Gerrard, R. D. Hutchinson, G. A. Mallinson, H. E. Matthews, V. O. Robinson and H. N. Smith.

THE BRITISH PHARMACEUTICAL CODEX, 1923.

In 1921 the revision of the book was undertaken by the Codex Revision Committee, and a new British Pharmaceutical Codex, embodying the supplements of 1915 and 1922, was published in June, 1923. This third Codex was prepared by the Codex Revision Sub-Committee consisting of Mr. E. White (*Chairman*), Dr. W. E. Dixon, Professor H. G. Greenish, Messrs. R. R. Bennett, W. Browne, C. E. Corfield, F. W. Gamble, A. Gunn, C. H. Hampshire, J. Keall, A. R. Melhuish, E. T. Neathercoat, J. Wicliffe Peck, F. Pilkington Sargeant, P. A. W. Self, H. Skinner and F. Browne (*Secretary*). The whole of the text was made concordant with the British Pharmacopœia, 1914, and the United States Pharmacopœia, 9th Revision. A large amount of new matter was inserted relating to medicaments the value of which was thought to be sufficiently established. The general plan of the 1911 Codex was left unaltered, but its chemical nomenclature was brought into line with modern views, and the description of the physiological action of many important substances was extended in accordance with the latest developments of medical research. For the convenience of users, the index was considerably enlarged and numerous additional cross-references were included.

CONSTITUTION OF REVISION COMMITTEES.

During the eleven years which have elapsed since the British Pharmaceutical Codex, 1923, was issued, changes of considerable magnitude in the practice of pharmacy have occurred, and the work has proved itself to be of ever-increasing value as a standard book of reference for pharmacists, medical practitioners and others. The need for a further revision of the whole book to justify the position to which it had risen was recognised by the Council of the Pharmaceutical Society in the formation of the Codex Committee in December 1929, to whom the general supervision and publication of a new British Pharmaceutical Codex was entrusted.

CODEx COMMITTEE.

The Codex Committee has consisted of the following members of the Council of the Pharmaceutical Society:—

H. Skinner, Ph.C., Chairman.

The President of the Pharmaceutical Society (*ex officio*).

The Vice-President of the Pharmaceutical Society (*ex officio*).

F. Gladstone Hincs.	E. T. Neathercoat, C.B.E., Ph.C.
*J. T. Humphrey, Ph.C.	L. Moreton Parry.
A. R. Melhuish, Ph.C.	E. Saville Peck, M.A., Ph.C.

With H. N. Linstead, Ph.C., as Secretary.

*Deceased.

On the recommendation of the Codex Committee, the Council appointed C. E. Corfield, B.Sc., F.I.C., Ph.C., to be the Editor of the British Pharmaceutical Codex, and H. Treves Brown, B.Sc., Ph.C., to be the Research Assistant in the Codex Laboratory.

CODEx REVISION COMMITTEE.

The task of revision and preparation was allocated to the Codex Revision Committee, consisting of the following members:—

H. Skinner, Ph.C., Chairman.

G. R. Boyes, B.Sc., F.I.C., Ph.C.	E. T. Neathercoat, C.B.E., Ph.C.
F. W. Gamble, Ph.C.	L. Moreton Parry.
F. Gladstone Hines.	E. Saville Peck, M.A., Ph.C.
*J. T. Humphrey, Ph.C.	P. A. W. Self, B.Sc., F.I.C.,
J. Keall.	Ph.C.
A. R. Melhuish, Ph.C.	T. E. Wallis, B.Sc., F.I.C.,
	Ph.C., F.L.S.

H. N. Linstead, Ph.C., Secretary.

The general work of revision has been divided into suitable sections and undertaken by the following sub-committees, who have co-operated freely and have submitted their recommendations to the Codex Revision Committee:—

PHARMACEUTICAL CHEMISTRY SUB-COMMITTEE.

P. A. W. Self, B.Sc., F.I.C., Ph.C., Chairman.

C. T. Bennett, B.Sc., F.I.C.,	T. A. Henry, D.Sc., F.I.C.,
Ph.C.	Ph.C.
*F. T. Brewis, F.I.C.	†B. F. Howard, F.I.C.
J. Evans, F.I.C., Ph.C.	W. H. Linnell, Ph.D., M.Sc.,
N. Evers, B.Sc., F.I.C.	F.I.C., Ph.C.
A. J. Ewins, D.Sc.	A. D. Powell, A.I.C.
	F. L. Pyman, D.Sc., F.R.S.

F. W. Adams, B.Sc., A.I.C., Ph.C., Secretary.

PHARMACOGNOSY SUB-COMMITTEE.

T. E. Wallis, B.Sc., F.I.C., Ph.C., F.L.S., Chairman.

H. Davis, B.Sc., A.I.C., Ph.C.	A. I. Robinson, Ph.C.
*H. G. Greenish, D.ès Sc., F.I.C.,	P. A. W. Self, B.Sc., F.I.C.,
Ph.C., F.L.S.	Ph.C.
C. Olive Griffiths, Ph.C.	T. M. Sharp, M.Sc., A.I.C.
F. Hemming, Ph.C.	G. R. A. Short, Ph.C.
W. O. Howarth, M.Sc.	J. Small, D.Sc., Ph.C., F.L.S.
H. O. Meek, Ph.C.	R. W. Wren.

A. J. Plowright, Ph.C., Secretary.

*Deceased.

†Resigned.

PHARMACY SUB-COMMITTEE.

J. Keall, Chairman.

W. J. Beardsley.	C. W. Maplethorpe, F.I.C., Ph.C.
H. Berry, B.Sc., A.I.C., Ph.C.	A. R. Melhuish, Ph.C.
†Agnes T. Borrowman, Ph.C.	C. A. Noble.
W. K. Fitch.	J. Wicliffe Peck, Ph.C.
F. G. Hobart, Ph.C.	R. H. Rowson, Ph.C.
*L. S. Lindley.	H. Skinner, Ph.C.

F. Browne, F.I.C., Ph.C., Secretary.

DRESSINGS SUB-COMMITTEE.

J. Keall, Chairman.

F. W. Barwick.	G. A. Mallinson.
S. Crabtree.	A. R. Melhuish, Ph.C.
A. W. Evans, B.Sc.	A. D. Powell, A.I.C.
F. Farrell.	H. Skinner, Ph.C.
F. W. Hooper, M.B.E.	H. N. Smith.
R. Hubbuck.	T. E. Wallis, B.Sc., F.I.C., Ph.C., F.L.S.
R. Dawson Hutchinson.	

F. Browne, F.I.C., Ph.C., Secretary.

ACTION AND USES SUB-COMMITTEE.

G. R. Boyes, B.Sc., F.I.C., Ph.C., Chairman.

H. E. Archer, M.R.C.S.; L.R.C.P., F.I.C., Ph.C.	C. Wilson Peck, Ph.C.
H. E. Chapman.	F. Purse.
*W. E. Dixon, M.D., F.R.S.	W. A. Robb, M.D., M.R.C.P., Ph.C.
W. K. Fitch.	H. Skinner, Ph.C.
*R. Fouracre, Ph.C.	J. G. Tait, M.R.C.S., L.R.C.P., Ph.C.
F. W. Gamble, Ph.C.	
*J. T. Humphrey, Ph.C.	

A. J. Plowright, Ph.C., Secretary.

*Deceased.

Whilst the principal object of the British Pharmaceutical Codex is to provide a book of reference for pharmacists and medical practitioners, the need for a book of standards for drugs and preparations not included in the British Pharmacopœia is self-evident. In consequence, the scope of the Codex has been considerably extended in order to provide manufacturers, dispensers and users with a more uniform standard and guide for the composition of numerous medicaments which, although in fairly constant demand, are not included in the Pharmacopœia because of their similarity in action

to other drugs, or because their use as remedies has not yet received general acceptance, or their value for the treatment of a particular disease has not been confirmed by more recent advances in medical science.

Many additional chemical substances have been described, new monographs have been added on certain vegetable and animal substances, many new formulæ have been devised or selected for inclusion, and, by the application of more modern scientific principles, a large number of existing formulæ have been considerably improved. The addition of so much new matter has necessitated drastic modification of the existing information on many substances which are only occasionally used in present-day pharmaceutical practice. In order of retain information which might occasionally be required, many to these substances have been described in the form of subsidiary monographs in smaller type. In this way it has been found possible to increase the volume of information regarding newer medicaments without losing the value of some information on the older substances now only in occasional demand.

The inclusion of monographs on surgical dressings and of several appendices has necessitated a change in the plan of the book, which is now arranged in four parts. Part I consists of monographs on chemical substances and drugs of vegetable and animal origin. Part II contains monographs on surgical dressings and the basic vegetable and animal fibres used in their manufacture. Part III contains the galenical and other preparations of the Codex, and corresponds to the Formulary section of previous volumes. Part IV is composed of appendices containing tables, general tests, reagents, methods of sterilisation, a pharmacological index, trade-names and proprietary substances, etc.

SOME IMPORTANT ADDITIONS.

Amongst the more important substances which have been added are the following:—

Acetarsol	Capsulæ Quininae et Cinnamomi
Acidum Hydrobromicum	Carbasus Chloraminæ
Æther Anæstheticus	Carbasus Eufllavinæ
Æthylenum	Carbo Activatus
Æthylhydrocupreinæ	Carbonei Dioxidum
Hydrochloridum	Cellulosum Ligni
Allobarbitonum	Decoctum Aloes Compositum
Ammonii Phosphas	Concentratum
Ammonii Tartras	Decoctum Cinchonæ Concentratum
Antimonii et Sodii Tartras	Decoctum Scoparii Concentratum
Antitoxinum Scarlatinum	Derris
Arsphenamina Argentica	Elixir Æthylmorphinæ et Terpini
Auri et Sodii Thiosulphas	Elixir Ephedrinæ Hydrochloridi
Azorubrum	Elixir Phenobarbitoni
Barbitonum Solubile	Elixir Thymi
Battista	Elixir Valerianæ Compositum
Bismuthum Præcipitatum	Emplastrum Adhesivum
Calci et Sodii Lactas	Emplastrum Zinci Oxidi
Capsulæ Quininae Ammoniatæ	Emulsio Acriflavinæ

Emulsio Olei Morrhuae et Creosoti
 Emulsio Paraffini Liquidi Alkalina
 Emulsio Paraffini Liquidi et Kaolini
 Ephedra
 Ephedrina
 Ephedrinæ Hydrochloridum
 Ergotoxinæ Æthanosulphonas
 Euflavina
 Extractum Apii Liquidum
 Extractum Aurantii Liquidum
 Extractum Ephedrae Liquidum
 Extractum Malti cum Vitaminis
 Extractum Papaveris Liquidum
 Extractum Parathyroidei
 Extractum Suprarenali Corticis
 Extractum Thymi Liquidum
 Extractum Valerianæ Liquidum
 Guttæ Physostigminæ Oleosæ
 Hexyl-resorcinol
 Holarrhena
 Indicarminum
 Infusum Cinchonæ Acidum
 Concentratum
 Injectio Camphoræ
 Injectio Digitalini
 Injectio Ferri et Arseni
 Injectio Peptoni
 Injectio Quininae et Urethani
 Injectio Sodii Morrhuatiss
 Insulinum
 Ligamentum Elasticum Adhesivum
 Ligamentum Pastæ Zinci
 Linimentum Aconiti Oleosum
 Liquor Azorubri
 Liquor Ergosterolis Irradiati
 Liquor Ferri Sulphatis Compositus
 Liquor Phenolis Alkalinus
 Liquor Tartrazinæ Compositus
 Liquor Vitaminæ-A
 Magnesii Sulphas Exsiccatus
 Maranta
 Mercurchromum
 Mistura Bismuthi Hydroxidi
 Mistura Bismuthi et Magnesii
 Hydroxidum
 Mistura Magnesii Hydroxidi et
 Paraffini Liquidi
 Mistura Quininae Salicylatis
 Nebula Adrenalinæ et Ephedrinæ
 Nebula Adrenalinæ et Ephedrinæ
 Oleosæ
 Nebula Ephedrinæ Composita
 Neoarsphenamina
 Nitrogenii Monoxidum
 Novaurantia
 Oestrinum
 Oleum Hippoglossi
 Oleum Hydnocarp
 Oleum Rapæ
 Oxygenium

Paradichlorbenzenum
 Paraffinum Liquidum Læve
 Pasta Magnesii Sulphatis
 Pasta Tragacanthæ Composita
 Phenobarbitonum
 Phenobarbitonum Solubile
 Pilulæ Ferri Carbonatis cum Arseno
 et Strychnina
 Pilulæ Ferri Carbonatis et Arseni
 Pilulæ Phenolphthaleini Compositæ
 Pinus Alba
 Potassii Hydroxyquinolini Sulphas
 Potassii Quadroxalas
 Procainæ Hydrochloridum
 Proflavina
 Psyllium
 Pulvis Barii Sulphatis Compositus
 Pulvis Effervescens Compositus
 Duplex
 Pulvis Effervescens Compositus
 Fortis
 Quininae Disalicylosalicylas
 Quininae Phosphas
 Saccharinum Solubile
 Sodii Chaulmoogras
 Sodii Morrhuas
 Sodii Phosphas Exsiccatus
 Sodii Sulphas Exsiccatus
 Solvellæ Acidi Tannici Compositæ
 Solvellæ Hydrargyri Oxycyanidi
 Spiritus Methylatus Industrialis
 Spiritus Methylatus Industrialis sine
 Acetono
 Sulpharsphenamina
 Suppositorium Bismuthi Subgallatis
 Suppositorium Bismuthi Subgallatis
 Compositum
 Syrupus Creosoti Compositus
 Syrupus Iodotannicus cum
 Phosphate
 Syrupus Pini Albæ Compositus
 Tabellæ Acidi Acetylsalicylici
 Compositæ
 Tabellæ Acidi Acetylsalicylici et
 Caffeinæ
 Tabellæ Acidi Acetylsalicylici et Opii
 Tabellæ Acidi Acetylsalicylici et Opii
 Compositæ
 Tabellæ Barbitoni et Amidopyrinæ
 Tabellæ Ferri Carbonatis et Aloini
 Tabellæ Leptandræ Compositæ
 Tabellæ Parathyroidei et Calcii
 Lactatis
 Tabellæ Phenobarbitoni et
 Theobrominæ
 Tartrazina
 Thallii Acetas
 Theophyllina
 Theophyllina et Sodii Acetas
 Tinctura Chloroformi et Morphinæ

Totaquina	Unguentum Rubri Scarlatini
Toxinum Scarlatinum	Unguentum Zinci cum Balsamo
Triethanolamina	Peruviano
Tryparsonum	Unguentum Zinci et Benzoino
Unguentum Acidi Borici Flavum	Unguentum Zinci cum Olei Ricini
Unguentum Ephedrinæ	Unguentum Zinci Morrhuatis
Unguentum Potassii Polysulphidi	Ventriculus Desiccatus

The monographs of the separate parts are arranged, as formerly, in alphabetical order under latinised names, with English equivalents and synonyms, and the abbreviations of the full Latin names have been introduced as in the British Pharmacopœia, 1932. Abbreviations for drugs and preparations of the British Pharmaceutical Codex, 1923, were contained in a supplement published in 1925. In general, the individual monograph is divided in a manner somewhat similar to that adopted previously, but its form has been modified in several important respects by which the information given is made more readily available and more definite and useful in character.

STANDARDS FOR CODEX SUBSTANCES.

One of the principal features of the book is the inclusion of a series of requirements and tests under the heading of "Standard," which provides for manufacturers, producers, and all engaged in the preparation of medicaments, a more uniform standard than has been available hitherto for many compounds and preparations not included in the British Pharmacopœia. In this connection it should be noted that the Food and Drugs (Adulteration) Act requires a drug to be of the nature, substance and quality demanded by the purchaser, but provides no standard by which the quality is to be determined. In their search for a standard, the courts have turned to the British Pharmacopœia, which has become a presumptive standard for the articles contained in it. The standards of the British Pharmaceutical Codex are those which experience has shown to be desirable as criteria of purity for substances when used for medicinal purposes, and to be such as may be attained without undue difficulty or expense. As in the case of the British Pharmacopœia, the standards have been designed to be applied solely when the substances are sold for medicinal purposes.

The monographs of Part I fall broadly into three groups. Firstly, those substances for which a standard is laid down in the British Pharmacopœia and which therefore do not require any additional tests of purity. In all such cases a summary of the official requirements following the heading "Standard, B.P." is included for information, but for the details of the tests and processes reference must be made to the British Pharmacopœia. Secondly, those substances for which a Codex standard is prescribed. In many of these monographs the tests included are those which have been found satisfactory in expert hands, and for some of the newer substances it has been found necessary to devise new series of tests and requirements in order to provide efficient control. Wherever it has been found possible to

apply tests and assay processes of the British Pharmacopœia to Codex substances, it has been considered unnecessary to repeat the details of these tests, and users of the standards are required to consult the Pharmacopœia and to adopt its methods of procedure when applying tests of purity. The general tests for purity and methods of assay of the articles of the British Pharmaceutical Codex are based upon the tests and processes of the British Pharmacopœia, 1932. The special tests for chlorides, sulphates, arsenic, lead, etc., the assay processes for chemicals, oils, biological products, etc., and the methods used for the determination of melting-points, boiling-points, optical rotations, etc., mentioned in the standards for substances, are not reproduced in the British Pharmaceutical Codex, and reference must be made to the British Pharmacopœia for particulars of these tests, assays and methods. Thirdly, those substances upon which general information is required and for which, on account of their limited direct medicinal uses, it has not been considered advisable to prescribe quantitative requirements and tests of purity. In such cases the absence of a standard does not indicate that it is permissible to use for medicinal purposes material containing injurious impurities. Chemical substances within this group should be tested to ascertain their freedom from appreciable amounts of dangerous impurities, and vegetable and animal products should be examined for avoidable foreign matter which may be injurious to health.

Most of the tests require reagents which are included either in the appendices of the British Pharmacopœia, or are described in the monographs or appendix of the British Pharmaceutical Codex. In applying the tests, the reagents used should be either those of the British Pharmacopœia or those of the British Pharmaceutical Codex, or corresponding substances of suitable reagent quality. Unless stated otherwise, temperatures are on the centigrade scale, and solubilities and specific gravities are determined at 15.5°. Where the term "alcohol" occurs in defining solubilities, alcohol (90 per cent.) is indicated. Residues obtained by the ignition or incineration of organic chemical substances are given in terms of "ash" values, and it must be noted that these values are calculated on the original substance and not, as with crude vegetable drugs, on the material dried at 100°.

In the case of substances such as organic arsenic compounds, sera, toxins and vaccines which are described, the tests must be made, in Great Britain and Northern Ireland, in accordance with the regulations made under the Therapeutic Substances Act, 1925, and in other parts of the British Empire in accordance with any local law that may be in force.

The sections of the monographs on vegetable drugs dealing with microscopical characters have been amplified, and special attention has been given to the provision of diagnostic characters by which the drugs may be identified with greater certainty, especially when

they occur in the crushed or powdered form. Information concerning different varieties occurring in commerce, and the description of commonly occurring substitutes, have been collected into separate paragraphs and thereby made more accessible. The situation regarding powdered drugs has required careful consideration, and, in view of the fact that a vegetable drug in powder can seldom be examined quantitatively for the proportion of foreign or other organic matter present, a separate paragraph has been added in the case of many of the more important crude drugs frequently met with in the powdered state. This paragraph in general indicates the state of purity which should be required for a vegetable powder without direct reference to the maximum percentage of foreign matter that should be present. Such powders should be prepared from material which complies with the standard for the unground drug, and in cases where the foreign organic matter is determinable, powders must comply with the limits for foreign organic matter.

ACTION AND USES.

The descriptions of the pharmacological action and therapeutic uses, and other matter included, as previously, in the section of the monograph under the heading "Action and Uses," have been revised in the light of modern knowledge, and in many cases rearranged so as to render the work more valuable to medical practitioners. Therapeutic notes, which formerly were included in the summaries of the preparations at the ends of the monographs, have, where it has been thought useful to retain them, been transferred to this section, and notes concerning modern pharmaceutical methods have in many cases been added, such as methods by which solutions and suspensions for administration by injection may be prepared and sterilised. References to other substances having a somewhat similar action, but differing in composition from the substance of the monograph, no longer appear in this section. Descriptions of the properties of such related substances appear in the form of subsidiary monographs or, in cases where they are met with under proprietary trade-names, in an appendix.

As formerly, doses are given at the end of the monograph, and it is intended that they should be interpreted in the same way as the doses given for substances of the British Pharmacopœia. They are expressed both in the metric and Imperial systems. In the former system, weights are given in multiples or fractions of a gramme, and volumes in multiples or fractions of a millilitre, it being considered no longer advantageous or convenient to use terms such as "decigram" or "centimil," or to continue the use of the word "mil," which has not been found acceptable for general scientific purposes.

SUMMARIES OF THE PREPARATIONS.

The summaries at the end of the monograph include those preparations of the British Pharmacopœia which are not included in the

book in any other form, and of the surgical dressings and galenical preparations of the Codex which are described in detail in Part II and Part III of the book. These summaries are included for the purpose of assisting the prescriber in his choice of the form of the drug that he wishes to administer. It has not been deemed advisable or considered necessary to include preparations from foreign pharmacopœias in view of the fact that the Pharmacopœia and the Codex now contain all such preparations which the medical practitioner should require. The notes include references to preparations of the International Agreement of , by which comparison may be made between preparations of the Codex and the requirements of the Agreement, and, by arrangement with the Pharmacopœia Commission, they indicate those preparations of the Codex which were contained in the British Pharmacopœia, 1914, and the changes which have been made in name or composition so that, if necessary, the preparation of the 1914 issue may be prepared from the formula of the Codex.

SURGICAL DRESSINGS.

The descriptions and requirements for surgical dressings in several cases have been extended and modified and, so far as possible, ambiguous statements concerning the strength of certain medicated dressings have been removed. Quantitative requirements are no longer obligatory in the case of dressings, such as phenol gauze, phenol tow and mercuric chloride gauze, from which, even when stored under the most favourable conditions, the medicament volatilises or is otherwise lost. In this section it has not been considered advisable to express measurements and weights of the dressings, or of the basic materials, entirely in the metric system. Hence, lengths and widths are expressed in inches and yards, and weights in grains and ounces (437.5 grains), whereas the metric system is retained for requirements and processes of a chemical nature. The test for neps in cotton wool has been revised to permit a quantitative comparison with an approved sample, and an arrangement has been made between the Council of the Pharmaceutical Society and the Manchester Testing House by which samples of cotton wool, not more neppy than the standard sample, may be obtained on application.

GALENICAL AND COMPOUNDED PREPARATIONS.

In the formulary section of the book several changes of importance have been made, including the addition of many new preparations and alterations in many of the older formulæ and processes. In this respect the formulary more accurately reflects modern pharmaceutical thought, and contains nearly every preparation or galenical, except those of the British Pharmacopœia, by means of which the more important drugs in present-day medical practice are administered or applied.

In deciding on the inclusion or omission of substances in common use, such as hair lotions and toilet preparations, which are not used for any medicinal properties they may happen to possess, notice has been taken of the fact that these articles are supplied by manufacturers according to their own formulæ, and where such preparations have been added or retained in the book, they have been included solely for the purpose of providing preparations suitable for use when dispensing the prescriptions of medical practitioners.

The preparations of former pharmacopœias, which are omitted from the British Pharmacopœia, and are still in frequent demand, are included as preparations of the Codex. Thus it has been possible to make improvements in the older preparations, in the same way as modern principles have been applied to former Codex preparations and those of the Pharmacopœia. This procedure, made possible by the co-operation and assistance of the Pharmacopœia Commission, has the additional advantage of making it possible for manufacturers to avoid having to prepare preparations from different authorities which show no differences in activity and may differ only slightly in composition or only in appearance. The same principle has been applied to preparations of the previous Codex which have been included in the British Pharmacopœia, 1932. Such articles have not been retained in the formulary, and information concerning any slight changes in composition is given in a note in the summary of the preparation at the end of the corresponding monograph.

The following preparations of the British Pharmacopœia, 1914, omitted from the British Pharmacopœia, 1932, have thus been included in Part III as preparations of the Codex:—

Acetum Cantharidini	Emplastrum Calefaciens
Acidum Nitricum Dilutum	Emplastrum Hydrargyri
Acidum Nitro-Hydrochloricum Dilutum	Emplastrum Menthol
Acidum Sulphuricum Aromaticum	Emplastrum Saponis
Aqua Anisi	Extractum Agropyri Liquidum
Aqua Aurantii Floris	Extractum Aloes
Aqua Carui	Extractum Belæ Liquidum
Aqua Fœniculi	Extractum Cannabidis Indicæ
Aqua Laurocerasi	Extractum Ergotæ
Aqua Menthæ Viridis	Extractum Euonymi
Aqua Rosæ	Extractum Gossypii Radicis Corticis Liquidum
Argenti Nitras Mitigatus	Extractum Grindeliæ Liquidum
Caffeinæ Citras Effervescent	Extractum Hydrastis Liquidum
Collodium	Extractum Kava Liquidum
Collodium Vesicans	Extractum Opii Liquidum
Confectio Piperis	Extractum Rhei
Confectio Rosæ Gallicæ	Extractum Strophanthi
Decoctum Agropyri	Extractum Taraxaci
Decoctum Aloes Compositum	Extractum Viburni Liquidum
Decoctum Gossypii Radicis Corticis	Glycerinum Pepsini
Decoctum Hamatoxyl	Glycerinum Plumbi Subacetatis
	Glycerinum Tragacanthæ

Infusum Aurantii Compositum	Pilula Saponis Composita
Infusum Cascariellæ	Pilula Scillæ Composita
Infusum Chiratæ	Pulvis Amygdalæ Compositus
Infusum Cinchonæ Acidum	Pulvis Antimonialis
Infusum Ergotæ	Pulvis Catechu Compositus
Infusum Krameriæ	Pulvis Cinnamomi Compositus
Infusum Rhei	Pulvis Kino Compositus
Infusum Rosæ Acidum	Pulvis Opii Compositus
Infusum Scoparii	Pulvis Scammoniae Compositus
Infusum Uvæ Ursi	Sevum Benzoatum
Injectio Morphinae Hypodermica	Sodii Citro-Tartras Effervescens
Injectio Strychninae Hypodermica	Spiritus Ammoniae Fetidus
Linimentum Ammoniae	Spiritus Anisi
Linimentum Calcis	Spiritus Armoraciae Compositus
Linimentum Chloroformi	Spiritus Cinnamomi
Linimentum Crotonis	Spiritus Juniperi
Linimentum Hydrargyri	Spiritus Lavandulae
Linimentum Opii	Spiritus Myristicae
Linimentum Potassii Iodidi cum Sapone	Spiritus Rosmarini
Linimentum Sinapis	Succus Scoparii
Liquor Acidi Chromici	Succus Taraxaci
Liquor Ammonii Citratis	Syrupus Acidi Hydriodici
Liquor Arsenici Hydrochloricus	Syrupus Aromaticus
Liquor Atropinae Sulphatis	Syrupus Aurantii Floris
Liquor Bismuthi et Ammonii Citratis	Syrupus Calcii Lactophosphatis
Liquor Calcis Chlorinatae	Syrupus Cascarae Aromaticus
Liquor Calcis Saccharatus	Syrupus Chloral
Liquor Ethyl Nitritis	Syrupus Codeinae Phosphatis
Liquor Ferri Perchloridi Fortis	Syrupus Ferri Phosphatis
Liquor Ferri Persulphatis	Syrupus Rhei
Liquor Formaldehydi Saponatus	Syrupus Rheoados
Liquor Hamamelidis	Syrupus Rosæ
Liquor Hydrargyri Nitratis Acidus	Tinctura Aconiti
Liquor Morphinae Acetatis	Tinctura Arnicae Florum
Liquor Morphinae Tartratis	Tinctura Berberidis
Liquor Potassii Permanganatis	Tinctura Buchu
Liquor Sodæ Chlorinatae	Tinctura Cannabis Indicae
Liquor Sodii Arsenatis	Tinctura Cantharidini
Liquor Zinci Chloridi	Tinctura Cascariellæ
Lithii Citras Effervescens	Tinctura Chiratæ
Lotio Hydrargyri Flava	Tinctura Chloroformi et Morphinae Composita
Magnesii Sulphas Effervescens	Tinctura Cinnamomi
Mistura Ammoniæ	Tinctura Cubebæ
Mistura Amygdalæ	Tinctura Ergotæ Ammoniata

Unguentum Eucalypti	

The following preparations of the British Pharmacopœia, 1914, have not been included as preparations of the Codex, but, where necessary, information concerning their composition is included in the text in Part I.—

Acetum Urginæ	Pulvis Buteæ Seminum
Decoctum Acaciæ Corticis	Pulvis Kaladanæ Compositus
Decoctum Ispaghulæ	Syrupus Urginæ
Decoctum Sappan	Tinctura Alstoniæ
Extractum Colchici	Tinctura Daturæ Seminum
Extractum Picrohizæ Liquidum	Tinctura Kaladanæ
Infusum Alstoniæ	Tinctura Oliveri Corticis
Injectio Apomorphinæ Hypodermica	Tinctura Picrohizæ
Injectio Cocainæ Hypodermica	Tinctura Podophylli Indici
Injectio Ergotæ Hypodermica	Tinctura Urginæ
Liquor Pancreatis	Tinctura Valerianæ Indicæ
Mucilago Gummi Indici	Ammoniata
Oxymel Urginæ	Unguentum Myrobalani
Pilula Ipecacuanhæ cum Urginea	Unguentum Myrobalani cum Opio
Pilula Urginæ Composita	Vinum Ipecacuanhæ

As in other parts of the book, the preparations of Part III are included in the alphabetical order of the latinised names, except in the case of the effervescent salts, which are arranged alphabetically in one group under the general heading of *Granulæ Effervescentes*.

The general information preceding most groups or classes of preparations has been rewritten, and for certain groups new paragraphs have been added. These sections, as formerly, contain general notes on the individual groups, and in some cases have been used for the purpose of offering advice to dispensers or of establishing rulings with reference to methods of dispensing.

In the sections on eye-lotions, pastilles, lozenges, tablets, and certain other preparations, formulæ consisting of a single active ingredient

which is frequently required in different strengths or varying doses are not included, and the general paragraph gives the strength of the preparation or the amount of medicament in each unit that should be supplied by the dispenser when the strength or quantity is not stated by the prescriber. The formulæ for tablets, which are now included under the more general name of *Tabellæ*, have been modified so as to permit of a reasonable variation in the quantities of substances used for granulating and lubricating. In the case of compound tablets, the quantities required to be present in each tablet are set out in a formula, but the kind and quantity of granulating and lubricating agents necessary may be varied or may be decided by reference to the instructions in the general paragraph. Formulæ for emulsions include definite quantities of emulsifying agents, but, in view of the fact that the amount required for the preparation of a satisfactory emulsion in a mortar may be much greater than is required to emulsify the same volume of oil by means of a homogeniser, permission is given in the general instructions to vary the amounts when necessary.

A change in the setting of the formulæ has been made, the older and sometimes ambiguous centesimal system has been replaced by the now widely used metric system, and the alternative and still very commonly used Imperial system has been retained. No ambiguity between the two systems will arise if it is observed that they are not interchangeable; in making any preparation, one or the other system must be followed in its entirety throughout. For convenience in the setting, under both systems weights and measures are expressed by abbreviations. Grammes and millilitres are represented by "g" and "ml" respectively, the former being now the more widely used abbreviation for gramme in scientific literature, and the latter the now universally recognised abbreviation for the millilitre. Metric measures used in the British Pharmaceutical Codex are graduated at 20°, and one litre of water in glass, at 20°, in air weighs therefore approximately 997 grammes. Imperial measuring vessels are graduated at 16·7°, and one fluid ounce of water, at 16·7°, in air, weighs 1 ounce (437·5 grains). A solution containing one-tenth of an ounce (43·75 grains) of a solid in 1 fluid ounce, therefore, is not exactly equivalent to a solution containing 10 grammes of a solid in 100 millilitres. Nevertheless, for all practical purposes the difference between corresponding percentage solutions in the two systems may be ignored. The tables in Appendix II for the conversion of percentages or formulæ in grammes per litre into percentages or formulæ in grains per pint, etc., in the Imperial system are based upon a 10 per cent. solution in the Imperial system which contains 43·75 grains of a solid in 1 fluid ounce of solution and not on 43·847 grains, which is the calculated figure based on a 10 per cent. solution in the metric system.

In the case of certain groups of preparations containing alcohol, namely, concentrated infusions, spirits and tinctures, figures are

included for the percentage of alcohol normally required to be present. Alcohol in formulæ for certain pharmaceutical preparations used externally, or which do not contain alcohol in the final product, and for the manufacture of certain other preparations may, by permission of the Board of Customs and Excise, be replaced by industrial methylated spirit, provided that the law and the statutory regulations are observed. A note at the end of the monograph is included to indicate whether, subject to the observance of the law and the regulations made under statute by the Board of Customs and Excise, industrial methylated spirit may be used.

THE APPENDICES.

The appendices contain much additional matter. The tables for the conversion of quantities in the metric system into equivalent quantities in the Imperial system have been condensed, and their use has been illustrated by suitable examples. The atomic weights are those agreed upon by the International Committee on Atomic Weights. A list of molecular weights in frequent use in analytical operations, and particulars of reagents used in the testing of chemical and vegetable substances and for certain clinical and other tests have been added. Other sections give the methods for conducting the arsenic and lead limits of Codex substances, particulars regarding colloidal solutions, and the methods by which solutions or preparations for injection should be sterilised.

The pharmacological index has been revised and modified considerably. It has been thought advisable to discontinue the inclusion of a general index of drugs based mainly on their therapeutic uses and on diseases, and to replace it by a list based, as far as possible, upon pharmacological principles.

The index of trade-names and proprietary substances is an important feature of the book. It contains trade-names for substances of the British Pharmacopœia and the British Pharmaceutical Codex, and for many substances which are only met with in commerce or used in medicine under registered or proprietary names. These are arranged alphabetically, information is given regarding their relation to the substances of the book, and an indication is given of the source from which further information may be obtained. The attention of pharmacists and dispensers is again directed to the fact that when a medicament is ordered under a proprietary trade-name, it is not permissible to substitute a similar product to which that trade-name does not legally apply.

CO-OPERATION AND ASSISTANCE.

The Codex Revision Committee have received invaluable advice and assistance from members of the Sub-Committees and from many other voluntary helpers, and they desire to record their indebtedness for the most generous and willing assistance which has been given and which has so greatly facilitated the work of revision.

The Committee acknowledge the assistance given by various experts who prepared or supplied material for monographs on certain special or miscellaneous substances, and to several correspondents and authors of scientific papers. In particular, the Committee are especially indebted to J. Blomberg, of The Hague; J. H. Burn, M.A., M.D.; Katharine H. Coward, D.Sc.; H. Deane, B.Sc., F.I.C., Ph.C.; E. Fielden; W. Forster, Ph.C.; A. T. Glenney, B.Sc.; C. H. Hampshire, M.B., B.S., B.Sc., F.I.C., Ph.C.; A. Harden, Ph.D., D.Sc., F.I.C., F.R.S.; G. A. Harrison, M.D., Ch.B.; Sir A. W. Hill, K.C.M.G., M.A., Sc.D., F.R.S.; W. M. Levitt, M.B., B.Ch., M.R.C.P.; G. Carmichael Low, M.A., M.D., F.R.C.P.; F. M. Medhurst; J. Mellanby, M.B., F.R.S.; C. C. Okell, M.C., M.B., M.R.C.S.; H. J. Parish, M.D., Ch.B., M.R.C.P.; R. A. Peters, M.A., M.D.; G. F. Petrie, M.D.; F. Ransom, Ph.C.; Sidney Smith, Ph.D., B.Sc., Ph.C.; the late Sir W. J. Simpson, C.M.G., M.D., F.R.C.P.; J. F. D. Shrewsbury, M.B., Ch.B.; Lt.-Col. W. D. H. Stevenson, C.I.E., M.A., M.D.; F. J. Todd, Ph.C., and to the members of the Pharmacy Consultative Committee, namely, J. J. Blackie, Ph.C.; H. Brindle, B.Sc., F.I.C., Ph.C.; J. H. Franklin, Ph.C.; A. J. Jones, A.I.C., Ph.C.; D. McCall, Ph.D., Ph.C.; A. G. C. Paterson, A.I.C., Ph.C.; J. Rae; T. M. Ridley, Ph.C.; J. Small, D.Sc., Ph.C., F.L.S.; J. Smith, Ph.C.; K. E. N. Williams, Ph.C.; T. Wilson, Ph.C., and A. E. Young, Ph.C.

The British Pharmaceutical Codex

PART I

ABRUS

(Abrus)

Abrus

Synonyms—Abri Semina; Jequirity; Jumble Beads; Prayer Beads.

Abrus consists of the seeds obtained from a small climbing plant, *Abrus precatorius* Linn. (Fam. Leguminosæ), which is a native of India and is now common in Brazil, the West Indies and other tropical countries.

The seeds are ovoid or sub-globular in shape and vary from 5 to 8 millimetres in length and from 4 to 5 millimetres in breadth; 100 seeds weigh from 14 to 14·5 grammes; they are hard with a smooth, glossy surface and of a bright, scarlet-red colour with a black patch at the hilum. Microscopically they show the characters common to leguminous seeds generally; the scarlet colour is due to the presence of a red colouring matter in the palisade epidermis of the testa and is changed to orange-red by alkalis; the black patch is due to a dark violet pigment in the palisade epidermis in that region. A very characteristic feature of the seeds is the sub-epidermal layer of the bearer cells; these are about six or seven times as high as they are wide and are connected with each other laterally by short projections in all directions; their height is about 150 microns. The cotyledons consist of very thick-walled pitted cells which contain protein but no starch.

Abrus **contains** two poisonous proteins, a paraglobulin and a phytoalbumose, a mixture of the substances being known as abrin. The activity of the globulin is destroyed at 75° to 80° and that of the albumose at 85°.

Substitutes.—Other varieties of abrus seeds occur in commerce. Two of them are white or yellow in colour, due to the absence of pigment from the palisade epidermis, and a third variety is entirely black. These varieties should not be used for making preparations.

Action and Uses.—Abrin resembles snake venom in its action and is much less poisonous when taken internally than when absorbed from wounds. Applied to mucous surfaces it acts as a violent irritant. For application to the eye in the treatment of granular lids and opacity of the cornea, an infusion of abrus (Infusum Abri; 1 in 12½) has been used. This should be freshly prepared since it decomposes rapidly unless about 2 per cent. of boric acid is added. It has been used diluted with from 2 to 20 parts of water, but must be employed with caution since it produces

inflammation that is dangerous and difficult to control, although its action can, to some extent, be checked by the application of hot compresses of solution of mercuric chloride (1 in 10,000). Its use should be discouraged.

ABSINTHIUM

(Absinth.)

Absinthium

Synonyms—Old Woman; Wormwood.

Absinthium consists of the dried leaves and flowering tops of *Artemisia Absinthium* Linn. (Fam. Compositæ), a perennial undershrub, indigenous to Northern Asia and Europe, and naturalised in the United States. It should be gathered when the plant is in flower.

The leaves are alternate, roundish-triangular, bi- or tripinnate and petiolate, the ultimate segments being linear-oblong and obtuse; the uppermost leaves (bracts) are entire, sessile and lanceolate. The inflorescence consists of hemispherical drooping capitula, each about 5 millimetres in diameter, arranged in a panicle; the florets are all tubular, pale yellow in colour and have no pappus. The entire herb is covered with a silky, grey tomentum and the receptacle with white, paleaceous hairs. It has an intensely bitter and aromatic taste and a strong, characteristic, aromatic odour.

The diagnostic **microscopical** characters are the epidermal cells with wavy side walls; stomata rare on the upper surface and numerous on the under surface; hairs of two kinds, balance hairs with a short, usually three-celled stalk, surmounted by a long, spindle-shaped cell, and glandular hairs typical of the family Compositæ; the spherical pollen grains with smooth walls and three pores; the hairs of the receptacle, each consisting of a short stalk and a large, ovoid, cylindrical, terminal cell reaching a length of 1 millimetre; the absence of calcium oxalate crystals.

Absinthium **contains** a volatile oil, of which the fresh herb yields about 0.3 per cent. The oil is dark green or sometimes blue in colour, and has a strong odour and a bitter, acrid taste. The oil contains thujone (absinthol or tanacetone, an isomeride of camphor), thujyl alcohol (both free and combined with acetic, isovalerianic and other acids), cadinene, phellandrene and pinene. The herb also contains the bitter glycoside, absinthin ($C_{15}H_{20}O_4$, silky crystals, melting-point, about 68°), a bitter principle, anabsinthin (crystalline, melting-point, about 258°), a yellow, crystalline substance, and absinthic acid.

Substitute.—The leaves and flowering tops of *Artemisia vulgaris* Linn., mugwort, are sometimes substituted for absinthium. Mugwort is distinguished by the dark green, almost glabrous, upper surface of the leaves, the under surface being densely tomentose, and by the slight odour and taste.

Standard.—Absinthium contains not more than 5 per cent. of

foreign organic matter and stems having a maximum width of more than 5 millimetres. Acid-insoluble ash, not more than 1 per cent.

Absinthium, in powder (*Pulvis Absinthii*: *Pulv. Absinth.*), contains the constituents and possesses the diagnostic microscopical characters of Absinthium, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—A characteristic action of absinthium is stimulation of the cerebral hemispheres, similar to the effect of camphor. Habitual use or large doses produce absinthism, which is shown by restlessness, vomiting, vertigo, tremors, and convulsions in which the patient loses consciousness, falls down, has clonic convulsions, may bite his tongue, pass water, and foam at the mouth. Absinthium is administered in the form of tincture. In most countries its use in wines is prohibited.

Preparation

Tinctura Absinthii, B.P.C.—(*Tinct. Absinth.*)—Tincture of Absinthium. 1 in 10.
Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

ACACIA

(*Acac.*)

Acacia

Synonyms—*Acaciæ Gummi*; Gum Acacia.

Acacia, a variety of gum arabic, is the dried gummy exudation from the stem and branches of *Acacia Senegal* Willd., a small tree indigenous to East and West Africa, and of some other species of *Acacia* (Fam. Leguminosæ). The gum exudes spontaneously from the stem and branches, but the flow is usually stimulated by incisions in the bark.

The gum occurs in rounded or ovoid tears about 0.5 to 4 or sometimes 6 centimetres in diameter. The tears are colourless or have a yellowish tint; they are brittle, opaque from the presence of numerous minute fissures and are often broken into angular fragments with glistening surfaces. Acacia is odourless and has a bland, mucilaginous taste. It is almost entirely soluble in water (1 in 1) forming a slightly acid solution or mucilage which is not ropy or glairy. It is insoluble in alcohol (90 per cent.). A 1 in 10 aqueous solution is slightly laevorotatory. The acid-insoluble ash is about 0.1 per cent.

Acacia **contains** arabin in combination with calcium, magnesium and potassium. It also contains oxidising, peroxidising and diastasic ferments, together with about 12 per cent. or more of water, and yields from 2.7 to about 4 per cent. of ash, consisting chiefly of calcium, magnesium and potassium carbonates. Arabin yields arabinose, galactose and glycuronic acid on hydrolysis.

Varieties.—Many varieties of acacia occur in commerce, but the most esteemed is that collected in Kordofan, the best varieties of which are almost colourless. Mogadore gum closely approaches it in quality, but is of less fine appearance. The best qualities of Senegal gum are also suitable for pharmaceutical use; they are less opaque than the Kordofan gum and contain occasional pieces of vermiform shape.

Substitutes.—Many dark coloured kinds of gum arabic occur in commerce and are used for various industrial purposes.

Standard, B.P.—Acacia loses, on drying at 100°, not more than 15 per cent. of its weight. Ash, not more than 5 per cent. It complies also with tests for the absence of starch, tannin and dextrin.

Acacia, in powder (*Pulvis Acaciæ*: *Pulv. Acac.*), contains the constituents and possesses the properties of Acacia, and complies with the standard for the unground drug.

Action and Uses.—Acacia is used medicinally as a demulcent and as a colloid. It is **administered** in mixtures, cough syrups and linctuses in the form of mucilage, in various jubes and pastilles, and as *Injectio Sodii Chloridi et Acaciæ* for intravenous injection. The colloid content and osmotic pressure of this injection are equal to those of the blood. It does not leave the blood vessels and is preferable, therefore, to saline solution alone. In cases of severe hæmorrhage from abdominal wounds and arteries it has great value in raising and maintaining the blood pressure. It is also used in cases of shock where the blood pressure has fallen dangerously low.

In dispensing, acacia is used as a pill excipient, either alone or as *Pulvis Acaciæ Compositus* which is a mixture of powdered acacia and powdered tragacanth in equal parts, and as a suspending agent in mixtures containing insoluble powders, but it is unsuitable with bismuth salts, with which it may form flaky masses. Powdered acacia is also used for the emulsification of fixed and volatile oils; in the case of fixed oils and oleoresins, one part of powdered acacia may be at once incorporated with four parts of the oil, the subsequent addition of twice as much water as acacia producing the primary emulsion; volatile oils require one part of acacia to two parts of oil; in the case of resinous tinctures, mucilage of acacia may be used in the proportion of not less than one-sixteenth part of the finished mixture. Solutions for **injection** may be sterilised by heating in an autoclave at 121° to 122° for one hour. Acacia is **incompatible** with strong alcohol, borax, ferric salts, calomel and lead subacetate, and with acids, unless well diluted.

GUMMI INDICUM.—Indian gum is an exudation from the stem of *Anogeissus latifolia* Wall. (Fam. Combretaceæ), a large tree indigenous to India and Ceylon. The gum occurs in rounded tears about 0.5 to 1 centimetre in diameter and in vermiform pieces about 0.5 centimetre in diameter and 3 to 4 centimetres long. The colour varies from yellowish-white to brownish; the surface is dull and somewhat rough, and free from cracks. It is brittle, with a glassy fracture, and the constituents resemble those of acacia. Indian gum has demulcent properties resembling those of gum arabic. It is an excellent emulsifying agent, and forms a nearly colourless mucilage with water. The mucilage (*Mucilago Gummi Indici*, 1 to 3) should be freshly prepared. Indian gum is used in India and the Eastern Colonies in making preparations for which acacia is used, but only 1 part of Indian gum is used instead of 2 parts of acacia.

Preparations

Injectio Sodii Chloridi et Acaciæ, B.P.—(Inj. Sod. Chlorid. et Acac.)—Injection of Sodium Chloride and Acacia. A sterile solution containing sodium chloride, 0·9 per cent. w/v, and acacia, 6 per cent. w/v, in freshly distilled water.

Mucilago Acaciæ, B.P.—(Mucil. Acac.)—Mucilage of Acacia. *Syn.*—Mucilage of Gum Acacia. Acacia, 40 per cent. w/w, dissolved in chloroform water. It should be stored in well-filled containers. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Pulvis Tragacanthæ Compositus, B.P.—(Pulv. Trag. Co.)—Compound Powder of Tragacanth. Tragacanth, 15 per cent., and acacia, 20 per cent., with starch and sucrose. Dose.—0·6 to 4 grammes (10 to 60 grains).

Syrupus Acaciæ, B.P.C.—(Syr. Acac.)—Syrup of Acacia. Mucilage of acacia, 1 in 4, in syrup. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

ACACIÆ CORTEX

(Acac. Cort.)

Acacia Bark

Synonyms—Babul Bark; Wattle Bark.

Acacia bark is the dried bark of *Acacia arabica* Willd. (Fam. Leguminosæ), a tree which grows in India, Arabia and Africa, and also of *A. decurrens* Willd., which is indigenous to Australia. The bark is collected from wild or cultivated trees at least seven years old and is allowed to mature for twelve months before use.

The bark of *A. arabica* (babul bark) is hard, reddish-brown in colour, frequently covered with a thick, blackish periderm, rugged, and much fissured longitudinally and transversely; the inner surface is reddish-brown, longitudinally striated and fibrous; it breaks with difficulty and exhibits a fibrous fracture; the taste is astringent. The bark of *A. decurrens* (wattle bark) is compact, in curved or channelled pieces, greyish-brown externally, darkening with age, often with irregular, longitudinal ridges; the inner surface is reddish-brown, finely striated longitudinally and, when broken, exhibits a coarsely fibrous fracture; the smoothed, transverse surface has a waxy appearance; the taste is astringent.

Babul bark **contains** about 20 per cent. of tannin and wattle bark contains about 22 to 36 per cent., the maximum amount being present in the bark of trees from seven to ten years old; gallic acid is also present.

Action and Uses.—Acacia bark is astringent. It is administered in the form of a decoction (Decoctum Acaciæ Corticis, 6 in 100; dose.— $\frac{1}{2}$ to 2 fluid ounces), which is also used as a gargle, lotion, or injection.

ACALYPHA

(Acalyph.)

Acalypha

Synonyms—Acalyphæ Herba; Indian Acalypha; Mukta-jhuri.

Acalypha consists of the fresh or dried entire plant, *Acalypha indica* Linn. (Fam. Euphorbiacæ), an erect, annual weed indigenous to the

plains of India, usually being found in the neighbourhood of habitations. It is collected when in flower.

The plant grows to a height of from 30 to 60 centimetres. The root is vertical, woody, somewhat tortuous and of a pale buff colour. The stem attains a diameter of about 5 millimetres; it is cylindrical and longitudinally grooved. The leaves are ovate to rhomboid ovate, about 5 by 3·5 centimetres in size, serrate, except the lower tapering part, 3-nerved, the two outer nerves branching on the outside only. The inflorescence consists of small axillary spikes of male and female flowers of a greenish colour. The spikes are shorter than the leaves and the female flowers are enclosed in funnel-shaped involucre.

Acalypha contains the alkaloid acalypine; other constituents are resin, tannin and volatile oil.

Substitutes.—*Acalypha paniculata* Miquel and other species of *Acalypha* are also used medicinally in India.

Action and Uses.—*Acalypha* is a gastro-intestinal irritant. It acts reflexly as an expectorant, but in large doses is an emetic; it has been used as a substitute for ipecacuanha.

ACETANILIDUM

(Acetanilid.)

Acetanilide

Synonym—Antifebrin.

Acetanilide, $\text{C}_6\text{H}_5\text{NH}\cdot\text{CO}\cdot\text{CH}_3$, may be prepared by the action of glacial acetic acid on aniline. It occurs in colourless, odourless, shining, lamellar crystals with a slightly pungent taste. When heated with sodium hydroxide solution, aniline is liberated, and the mixture, if warmed with a little chloroform, develops the unpleasant odour of phenyl isocyanide. The aqueous solution gives with bromine solution a yellowish-white precipitate.

Soluble in water (1 in 210), boiling water (1 in 18), alcohol (90 per cent.) (1 in 4·2), chloroform, ether, acetone, benzene and glycerin; slightly soluble in light petroleum.

Standard.—Acetanilide melts between 113° and 115° . Ash, not more than 0·1 per cent. Shake 1 gramme with 20 millilitres of water and filter; the filtrate is not affected by ferric chloride solution (distinction from phenacetin), and is neutral to litmus paper.

Action and Uses.—In fever, acetanilide produces a marked fall in temperature which is accompanied by profuse perspiration and is probably due to direct depression of the heat-regulating mechanism of the brain. Large doses depress the circulation and the heart with

consequent collapse, and also lead to the formation of methæmoglobin from the hæmoglobin of the blood, which is then no longer able to take up oxygen, and cyanosis results. The formation of methæmoglobin may also result from continued use. Some persons are exceedingly susceptible to acetanilide, and even small doses will lead to cyanosis and collapse; occasionally erythematous rashes occur. Should caffeine or the opium alkaloids be given with acetanilide its toxicity is raised; with sodium bicarbonate or alkalis generally its toxicity is lowered. Acetanilide possesses distinct pain-allaying power, which appears to be due to depression of the basal ganglia of the brain, and not the cerebral cortex as in the case of morphine. It is employed for the relief of neuralgia, myalgia, migraine, the pain of influenza, sciatica, the crises of locomotor ataxy, and pain of uterine or ovarian origin such as that of dysmenorrhœa. When applied locally to mucous membrane or to denuded surfaces, it has a slight analgesic action. It is used for relieving the pain of ulcers, but not more than a small proportion of a dusting powder should consist of acetanilide, since it may be absorbed in quantity sufficient to produce toxic symptoms.

Acetanilide may be **administered** in cachets or in the form of powders or tablets. It may be suspended in water with the aid of mucilage of acacia or compound powder of tragacanth. With many organic substances, including chloral hydrate, phenol, thymol and resorcinol, acetanilide may form pasty masses; with spirit of nitrous ether it may produce a yellow or red colouration which may be delayed if a little sodium bicarbonate is added previously. In cases of **poisoning** by acetanilide an emetic should be given, or the stomach washed out with an alkali; warmth should be applied to the feet and body and means adopted to increase the activity of the medullary centres, especially the respiratory and vasomotor; strychnine in doses of $\frac{1}{30}$ grain, administered subcutaneously, is valuable, and artificial respiration may be required.

Dose.—0·12 to 0·3 gramme (2 to 5 grains). Doses exceeding 5 grains are sometimes ordered, but in susceptible individuals may cause alarming symptoms.

Preparations

Pulvis Acetanilidi Compositus, B.P.C.—(Pulv. Acetanilid. Co.)—Compound Acetanilide Powder. Acetanilide, 70 per cent.; caffeine, 10 per cent., sodium bicarbonate, 20 per cent. Dose.—0·2 to 0·3 gramme (3 to 5 grains).

Tabellæ Acetanilidi Compositæ, B.P.C.—(Tab. Acetanilid. Co.)—Compound Tablets of Acetanilide. Each tablet contains 2 grains of acetanilide, $\frac{1}{2}$ grain of caffeine and 1 grain of sodium bicarbonate. Dose.—1 or 2 tablets.

Tabellæ Acetanilidi Compositæ cum Codeina, B.P.C.—(Tab. Acetanilid. Co. c. Codein.)—Compound Tablets of Acetanilide with Codeine. Each tablet contains 2 grains of acetanilide, $\frac{1}{2}$ grain of caffeine, 1 grain of sodium bicarbonate and $\frac{1}{4}$ grain of codeine. Dose.—1 or 2 tablets.

ACETANNIN

(Acetann.)

Acetannin*Synonym*—Acetyltannic Acid.

Acetannin may be obtained by heating tannic acid with acetic anhydride on a water-bath for one hour, adding alcohol to the mixture, pouring into water, and drying the washed precipitate at a temperature not exceeding 60°. It varies in composition and is probably a complex mixture of partially acetylated derivatives of tannin. Acetannin occurs as a yellowish or greyish-white powder which darkens on exposure to light. It is odourless or has a faintly acetous odour. When dissolved in solutions of the alkalis or alkali carbonates it decomposes gradually into alkali tannate and acetate, the solution gradually deepening in colour. It is precipitated by the addition of water to its solution in acetic acid. On shaking 0·2 gramme with 2 millilitres of alcohol and 2 millilitres of sulphuric acid the odour of ethyl acetate is developed. It should be **stored** in the dark in a dry place and in well-closed containers.

Soluble in ethyl acetate and solutions of borax and of sodium phosphate; very slightly soluble in water, alcohol and ether.

Standard.—Acetannin loses, on drying at 100°, not more than 3 per cent. of its weight. Ash, not more than 0·3 per cent. Shake 5 grammes for five minutes with 95 millilitres of water and filter into a Nessler glass, add 2 millilitres of ferrous tartrate solution and dilute to 100 millilitres; the colour produced is not deeper than that produced by 0·01 gramme of tannic acid (limit of tannic acid). Shake 1 gramme for five minutes with 50 millilitres of water and filter; 25 millilitres of the filtrate requires not more than 1·2 millilitres of N/10 sodium hydroxide for neutralisation, using phenolphthalein as indicator (limit of free acid). Not more than 3 per cent. of soluble matter is extracted on shaking 1 gramme with 200 millilitres of water at frequent intervals during two hours (limit of soluble matter).

Action and Uses.—Acetannin was introduced as a substitute for tannic acid for use as an intestinal astringent, on the supposition that, being insoluble in weak acid, it would pass through the stomach unchanged and be decomposed into alkali tannate in the duodenum. This change takes place only in part; some of the acetannin passes through the alimentary canal without decomposition, and a trace is absorbed as sodium gallate and excreted in the urine. Acetannin is used for the treatment of acute intestinal catarrh after the cause of the inflammation has been removed, and also for the chronic diarrhoea of children. It should be **administered** in cachets or mixed with lactose and suspended in milk. It is **incompatible** with alkalis, salts of iron and bismuth subnitrate.

Dose.—0·3 to 0·6 gramme (5 to 10 grains).

METHYLENEDITANNIN.—Methyleneditannin, or methylditannin, is a condensation product of tannic acid and formaldehyde and may be prepared by mixing aqueous solutions of tannic acid and formaldehyde, precipitating completely with hydrochloric acid, washing the product with water, and drying at a moderate temperature. It occurs as a pale fawn to chocolate-brown, odourless, tasteless powder melting at about 220° to 240° , with decomposition. It is insoluble in water or acids, soluble in alcohol and the usual organic solvents, also in solutions of ammonia with yellow colouration, and in solutions of sodium and potassium hydroxides with reddish-brown colouration. Methyleneditannin is antiseptic and astringent and has been given internally for diarrhoea. It may be used as a dusting powder, either alone or diluted with starch, 1 in 5, or 1 in 10, for eczema, pruritus and bedsores. Dose.—0.3 to 1 gramme (5 to 15 grains).

ACETARSOL

(Acetarsol)

Acetarsol

Synonym—Acetarsone.

Acetarsol, $\text{CH}_3\text{CONH}\cdot\text{C}_6\text{H}_3(\text{OH})\text{AsO}(\text{OH})_2$, is 3-acetylamino-4-hydroxyphenylarsonic acid, and may be prepared by the reduction of 3-nitro-4-hydroxyphenylarsonic acid and subsequent acetylation of the amino-acid thereby produced. It forms a sodium salt which is a white powder soluble in about eight parts of cold water. Acetarsol occurs as a white, crystalline powder and melts at 240° to 250° .

Practically **insoluble** in cold water; moderately soluble in boiling water; insoluble in alcohol and dilute acids; soluble in dilute alkalis.

Standard.—Acetarsol contains not less than 27.0 and not more than 27.4 per cent. of As. 5 millilitres of the solution, obtained by shaking 1 gramme with 10 millilitres of water and filtering, complies with the limit test for chlorides. 0.1 gramme suspended in 1 millilitre of chromic acid solution does not impart a brown colour to the solution (limit of free amino-acid).

Assay.—Dissolve 0.2 gramme, accurately weighed, in about 20 millilitres of water by the addition of a few drops of N/1 sodium hydroxide, add 5 grammes of ammonium persulphate and boil the solution until colourless. Add 40 millilitres of 2N oxalic acid and boil until carbon dioxide ceases to be evolved, add 10 millilitres of 2N sulphuric acid and 1 gramme of potassium iodide and boil until the solution assumes a pale straw colour; decolourise by the addition of a drop or two of N/10 sodium thiosulphate, dilute with water to about 150 millilitres, add 30 millilitres of 2N sodium carbonate and an excess of sodium bicarbonate, and titrate with N/10 iodine, using mucilage of starch as indicator; each millilitre of N/10 iodine is equivalent to 0.003747 gramme of As.

Action and Uses.—Acetarsol possesses the advantage over the arspenamines of being therapeutically active when given by the mouth. It has been used in the treatment of syphilis, malaria, yaws

and relapsing fever, as well as in amœbiasis, and may be of value in the virus infections. In chronic cases of amœbic dysentery which have become emetine resistant, 0.25 gramme (4 grains) by the mouth, twice daily, is of special value, as also in cases in which emetine is contra-indicated, namely, cardiac lesions, pregnancy, and for children. It may also be combined with emetine. A single dose of 1 gramme of acetarsol by the mouth, or of its sodium salt intravenously or intramuscularly, is effective in removing the simple tertian parasites of malaria from the blood stream, but malignant tertian and quartan forms are unaffected. Acetarsol has been used in the prophylactic treatment of suspected cases of syphilis. In the treatment of general paralysis the best results are obtained in megalomania and psychical disturbances. Injections of 0.5 to 1.5 grammes (8 to 25 grains) of the sodium salt are given three times a week until 20 grammes in all has been given. Solutions for **injection** may be prepared by aseptic methods. Various toxic effects of acetarsol have been recorded; they do not differ from those seen after the administration of neoarsphenamine. Premedication with dextrose and alkalis is important.

Dose.— For children, 0.03 gramme ($\frac{1}{2}$ grain); for adults, 0.25 gramme (4 grains).

ACETONUM

(Aceton.)

Acetone

Acetone, or dimethylketone, $\text{CH}_3\cdot\text{CO}\cdot\text{CH}_3$, may be prepared by the fractionation of pyroligneous acid, by the dry distillation of barium acetate, or, with butyl alcohol, by the Fernbach process, in which starch is fermented by a special ferment. It may also be obtained synthetically from acetylene. Acetone occurs as a clear, colourless, mobile and volatile liquid, with a characteristic odour and a pungent, sweetish taste. A 0.5 per cent. aqueous solution with a few drops of sodium nitroprusside solution and sodium hydroxide solution, on the addition of a slight excess of acetic acid, produces a deep red liquid which turns violet on dilution with water.

Acetone occurs in small quantities as a constituent of normal urine, and in larger amounts in that of diabetics. It may be detected by the nitroprusside test or by the following salicylaldehyde test: when to 10 millilitres, 1 gramme of potassium hydroxide and 10 drops of salicylaldehyde are added and the mixture warmed to 70° without shaking, a purplish-red ring develops; as little as 0.0001 per cent. of acetone in aqueous solution can be detected by this test, which is not given by either methylethylketone or aromatic ketones. 10 millilitres of a 0.1 per cent. solution in alcohol (50 per cent.), on the addition of 1 millilitre of 1 per cent. solution of *o*-nitrobenzaldehyde in alcohol (50 per cent.) followed by 1 millilitre of 15 per cent. sodium hydroxide solution, produces on acidification with acetic acid a bluish-green

colouration. Absolute acetone boils at 56.5° . As found in commerce, acetone contains about 99 per cent. by weight of absolute acetone. It is inflammable, its flash-point being 1.8° . It should be stored in well-closed containers in a cool place, remote from fire or lights.

Miscible with water, alcohol (90 per cent.), methyl alcohol, ether, fatty acid esters, and chloroform, in all proportions.

Standard, B.P.—Acetone has a specific gravity of 0.796 to 0.801. Not less than 95 per cent. distils between 56° and 58° . Residue on evaporation, not more than 0.01 per cent. w/v. It complies also with tests for alkalinity, acidity, methyl alcohol and other readily oxidisable substances, and for solubility in carbon disulphide.

Action and Uses.—The physiological action of acetone is similar to that of ethyl alcohol. Acetone is only occasionally administered internally and has been used in the form of a spray for inhalation in dyspnoea and spasmodic conditions such as asthma, but is of little value. It is used as a vehicle for volatile oils for inhalation. Acetone should not be used as a solvent for iodine, since the vapours of the solution are extremely irritating to the eyes. It is a useful solvent for resins, fats, cantharidin, pyroxylin, celluloid, etc.; owing to its low boiling-point, it is also a good menstruum for extracting certain drugs, since the extract can be evaporated at low temperatures.

ACETOPHENONUM.—Acetophenone, or phenylmethylketone, $C_6H_5 \cdot CO \cdot CH_3$, occurs as a colourless or slightly yellowish, oily liquid, with an odour recalling that of bitter almond and jasmine. It melts at about 18° and boils at 200° ; specific gravity, about 1.035. It is insoluble in water, but very soluble in alcohol, ether, chloroform, olive oil and almond oil. Acetophenone has been used as a hypnotic, but is uncertain in its action and is liable to cause ill effects. A solution in almond oil (1 in 10) may be administered as an emulsion or in gelatin capsules. Dose.—0.2 to 0.5 millilitre (3 to 8 minims).

ALCOHOL DIACETONICUM.—Diacetone alcohol, or diacetone, $(CH_3)_2C(OH)CH_2 \cdot CO \cdot CH_3$, may be obtained by the action of alkalis on acetone. When pure, it occurs as an odourless, colourless liquid, miscible with water, alcohol and benzene. The commercial product has a specific gravity of about 0.915 to 0.945 and a boiling-range of about 160° to 166° . It is used as a solvent in the manufacture of lacquers and varnishes.

BENZOPHENONUM.—Benzophenone, or diphenylketone, $(C_6H_5)_2CO$, occurs in white, rhombic crystals of pronounced aromatic odour. Melting-point, about 48° ; boiling-point, about 306° . It is insoluble in water, but readily soluble in alcohol and ether. Benzophenone is the typical aromatic ketone used in experimental comparisons of different groups of hypnotics; its hypnotic properties are inferior to those of the aliphatic ketones. Dose.—0.2 to 0.5 gramme (3 to 8 grains).

ACIDUM ACETICUM

(Acid. Acet.)

Acetic Acid

Acetic acid may be obtained by the destructive distillation of wood, or by the dilution of glacial acetic acid. It occurs as a clear, colourless, pungent liquid with a sharp, acid taste.

Miscible with water, alcohol (90 per cent.) and glycerin, in all proportions.

Standard, B.P.—Acetic acid contains not less than 32.5 per cent. and not more than 33.5 per cent. w/w of $C_2H_4O_2$. Specific gravity, 1.044 to 1.045. Residue on evaporation, not more than 0.01 per cent. w/w. Arsenic limit, 2 parts per million. Lead limit, 1 part per million. It complies also with limit tests for chloride, sulphate, oxidisable impurities and formic acid.

Action and Uses.—Acetic acid is oxidised in the body and is excreted in the urine as carbonate; it is mildly diaphoretic, diuretic and expectorant. Applied externally, it has an irritant action, and is therefore useful in liniments. The acid, well diluted (1 in about 30), is employed as a gargle. Acidum Aceticum Dilutum is used to sponge the skin in fevers and as a lotion for the scalp. It is **administered** in mixtures in the form of the dilute acid, oxymel, or oxymel of squill.

ACETUM.—Malt vinegar is produced by the oxidation of fermented malt-wort by means of the organism, *Mycoderma aceti*. It occurs as a brown liquid and contains not less than 4 per cent. w/v of $C_2H_4O_2$, with traces of other organic acids, sugar, dextrin, colouring matter and characteristic esters. Malt vinegar contains at least 0.05 per cent. of phosphates, calculated as P_2O_5 , and about 1.5 to 3 per cent. of solid matter. Specific gravity, 1.014 to 1.025. Malt vinegar has the action of dilute acetic acid and is used as a domestic remedy as a lotion for bruises and sprains.

CRUDE PYROLIGNEOUS ACID is the brown aqueous liquid obtained in the destructive distillation of wood. It contains methyl alcohol, acetic acid, acetone, and numerous other substances. Rectified pyroligneous acid is obtained from the crude acid by distillation.

Preparations

Acetum Odoratum, B.P.C.—(Acet. Odorat.)—Toilet Vinegar. Acetic acid, 1 in 8, with odorants. For aromatic vinegar, see Acidum Aceticum Aromaticum (under Acidum Aceticum Glaciale).

Acidum Aceticum Dilutum, B.P.—(Acid. Acet. Dil.)—Dilute Acetic Acid. It contains 6 per cent. w/w of $C_2H_4O_2$ (limits, 5.7 to 6.3). Specific gravity, about 1.008; arsenic limit, 0.4 part per million; lead limit, 0.5 part per million. It complies also with limit tests for readily oxidisable impurities, formic acid and oxidisable impurities, chloride, sulphate and residue on evaporation. Dose. 2 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

ACIDUM ACETICUM GLACIALE

(Acid. Acet. Glac.)

Glacial Acetic Acid

Glacial acetic acid, $CH_3 \cdot COOH$, may be obtained by the distillation of dried sodium or calcium acetate with strong sulphuric acid, or by synthesis. It occurs as a clear, colourless liquid, or as a colourless, crystalline mass, with a strong pungent odour. At temperatures below 10°

it crystallises, and melts again at about 15° . Boiling-point, about 117° , the acid distilling unchanged. A variety of glacial acetic acid melting at 10° is also met with in commerce. Acid of "60°" is a commercial variety; it melts at 15.5° and corresponds to an acid stronger than 99 per cent. The addition of a small amount of water lowers the melting-point considerably, an acid containing about 13 per cent. of water melting below 0° . The acid is not inflammable at ordinary temperatures, but the vapour burns with a blue flame. Flash-point, about 44° .

Miscible with water, and with most fixed and volatile oils.

Standard, B.P.—Glacial acetic acid contains not less than 99 per cent. w/w of $C_2H_4O_2$. Freezing-point, not less than 14.8° . Specific gravity, 1.055 to 1.058. Residue on evaporation, not more than 0.01 per cent. w/w. Arsenic limit, 6 parts per million. Lead limit, 3 parts per million. It complies also with limit tests for chloride, sulphate, oxidisable impurities and formic acid.

Action and Uses.—Glacial acetic acid is not administered internally. When inhaled by the nostrils glacial acetic acid induces a reflex stimulation of the medullary centres. It is, therefore, employed together with odorants, as in *Acidum Aceticum Aromaticum*, as a restorative and stimulant in cases of fainting. Externally, it is used as a rubefacient, vesicant or caustic, according to the length of time it is in contact with the skin. It is commonly employed for the destruction of warts and corns. In cases of **poisoning** by glacial acetic acid large draughts of water containing soap or magnesia, chalk and oil, or gruel, should be given.

ACETIC ANHYDRIDE, $(CH_3CO)_2O$, is a colourless liquid. Specific gravity, about 1.085. Boiling-point, about 138° . It is not employed medicinally, but large quantities are used as a reagent and in the manufacture of acetyl derivatives.

Preparation

Acidum Aceticum Aromaticum, B.P.C.—(Acid. Acet. Aromat.)—Aromatic Acetic Acid. *Syn.*—Aromatic Vinegar. Glacial acetic acid, approximately 74 per cent. v/v, with odorants. For toilet vinegar, see *Acetum Odoratum* (under *Acidum Aceticum*).

ACIDUM ACETYLSALICYLICUM

(Acid. Acetylsalicyl.)

Acetylsalicylic Acid

Synonym—Aspirin.

Acetylsalicylic acid $C_6H_4(O \cdot CO \cdot CH_3) \cdot COOH$, is *o*-acetoxybenzoic acid, and may be prepared by the action of acetic anhydride or acetyl

chloride on salicylic acid. The general use of the synonym "aspirin" is limited to Great Britain and Northern Ireland. It occurs in colourless, odourless, acicular crystals, or as a white, crystalline powder, with a slightly acid taste. It dissolves in solutions of alkalis and alkali carbonates, and in solutions of alkali citrates and ammonium acetate with partial decomposition and formation of salicylates. Boil 0.5 gramme for a few minutes with 10 millilitres of sodium hydroxide solution, cool, and add an excess of dilute sulphuric acid; a crystalline precipitate, giving the reactions of salicylates, is produced, and an odour of acetic acid is perceptible. 0.1 gramme, boiled with 10 millilitres of water, gives a violet-red colouration with one drop of ferric chloride solution. Acetylsalicylic acid is stable in dry air, but in contact with moisture it gradually hydrolyses into acetic and salicylic acids. It should be **stored** in well-stoppered bottles, in a dry place.

Soluble in water (about 1 in 300), alcohol (90 per cent.) (1 in 5), ether (about 1 in 20) and chloroform (1 in 17).

Standard, B.P.—Acetylsalicylic acid contains not less than 99.5 per cent. of $C_9H_8O_4$. Melting-point, 135° to 138° . Ash, not more than 0.05 per cent. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. It complies also with limit tests for readily carbonisable substances and free salicylic acid.

Action and Uses.—Acetylsalicylic acid is antipyretic and analgesic. It is slowly decomposed in the alimentary tract, yielding salicylic acid and salicylates; its action, therefore, resembles, but is stronger than, that of sodium salicylate. Acetylsalicylic acid is eliminated rapidly by the kidneys, excretion beginning only a short time after the drug is administered. The acid is prescribed in rheumatic conditions, including rheumatic fevers, for headache, neuralgia and influenza. In certain individuals, relatively small doses of acetylsalicylic acid produce violent reactions, of which skin eruptions and asthma are the most common symptoms. Acetylsalicylic acid may be **administered** in cachets, powders, tablets, as a mixture in which the acid is suspended by means of compound powder of tragacanth, or dissolved by the aid of potassium citrate or solution of ammonium acetate. The powder is applied locally at frequent intervals in the early stages of tonsillitis and after the removal of tonsils. Acetylsalicylic acid with Dover's powder is given as an antipyretic in acute febrile diseases, and in conjunction with phenacetin as an analgesic. Doses of 1.3 to 2.6 grammes (20 to 40 grains) are sometimes given by rectal injection before operations. **Poisoning** by acetylsalicylic acid is treated by emetics or lavage of the stomach, followed by cardiac and other stimulants.

Dose.—0.3 to 1 gramme (5 to 15 grains).

ACIDUM CITROSALICUM.—Citrosalic acid is methylenecitrylsalicylic acid, $C_{19}H_{14}O_7(COOH)_2$, and occurs as a white, odourless, almost tasteless, crystalline powder, melting at about 145° . It is hydrolysed by alkalis. It is almost insoluble in water, but soluble in alcohol and, with difficulty, in chloroform and ether.

Preparations

Mistura Acidi Acetylsalicylici, B.P.C.—(Mist. Acid. Acetylsalicyl.)—Mixture of Acetylsalicylic Acid. *Syn.*—Aspirin Mixture. Each fluid ounce contains 15 grains of acetylsalicylic acid with compound powder of tragacanth and chloroform water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Mistura Acidi Acetylsalicylici Composita, B.P.C.—(Mist. Acid. Acetylsalicyl. Co.)—Compound Mixture of Acetylsalicylic Acid. *Syn.*—Compound Aspirin Mixture. Each fluid ounce contains 15 grains of acetylsalicylic acid and 30 grains of potassium citrate with syrup of lemon and chloroform water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Tabellæ Acidi Acetylsalicylici Compositæ, B.P.C.—(Tab. Acid. Acetylsalicyl. Co.)—Compound Tablets of Acetylsalicylic Acid. *Syn.*—Compound Aspirin Tablets. Each tablet contains $3\frac{1}{2}$ grains of acetylsalicylic acid, $2\frac{1}{2}$ grains of phenacetin and $\frac{1}{4}$ grain of caffeine. Dose.—1 or 2 tablets.

Tabellæ Acidi Acetylsalicylici et Caffeini, B.P.C.—(Tab. Acid. Acetylsalicyl. et Caffein.)—Tablets of Acetylsalicylic Acid and Caffeine. Each tablet contains 4 grains of acetylsalicylic acid and 1 grain of caffeine. Dose.—1 to 3 tablets.

Tabellæ Acidi Acetylsalicylici et Opii, B.P.C.—(Tab. Acid. Acetylsalicyl. et Opii)—Tablets of Acetylsalicylic Acid and Opium. *Syn.*—Tablets of Aspirin and Dover's Powder. Each tablet contains $2\frac{1}{2}$ grains of acetylsalicylic acid and $2\frac{1}{2}$ grains of powder of ipecacuanha and opium. Dose.—1 to 3 tablets.

Tabellæ Acidi Acetylsalicylici et Opii Compositæ, B.P.C.—(Tab. Acid. Acetylsalicyl. et Opii Co.)—Compound Tablets of Acetylsalicylic Acid and Opium. Each tablet contains 3 grains of acetylsalicylic acid, $1\frac{1}{4}$ grains of phenacetin and 1 grain of powder of ipecacuanha and opium. Dose.—1 to 4 tablets.

ACIDUM AGARICUM

(Acid. Agaric.)

Agaric Acid

Synonym—Agaricin.

Agaric acid is obtained from *Fomes officinalis* Faull. (Fam. Polyporaceæ), a fungus growing on larch trees. It occurs as a nearly white, microcrystalline powder, which is almost odourless and tasteless.

Slightly **soluble** in water and alcohol (1 in 130); solutions in caustic alkalis froth freely.

Standard.—Agaric acid melts at about 140°. Ash, not more than 0·5 per cent. It dissolves in boiling water to form a perfectly clear foaming liquid.

Action and Uses.—The characteristic effect of agaric acid is to cause tonic contraction of plain muscle throughout the body. When given by the mouth it acts as an anhidrotic and it has been suggested that this action is produced by tonic contraction of the muscle surrounding the sweat glands. The chief use of agaric acid is for controlling the night-sweats in phthisis and other forms of hyperhidrosis. It is superior to atropine in that it does not cause dryness of the mouth and throat, and has little effect on the pupil of the eye, although it is more apt to

upset digestion. It is absorbed slowly, and the dose should therefore be taken some hours before retiring. Agaric acid may be **administered** in pills or cachets; since large doses have a purgative action, some preparation of opium is frequently added. It should not be administered hypodermically, since it causes intense pain and inflammation at the site of injection.

Dose.—0.005 to 0.03 gramme ($\frac{1}{200}$ to $\frac{1}{20}$ grain).

ACIDUM BENZOICUM

(Acid. Benz.)

Benzoic Acid

Benzoic acid, $\text{C}_6\text{H}_5\cdot\text{COOH}$, may be obtained from benzoin, storax and balsams of tolu and Peru, in which it occurs naturally, or it may be prepared synthetically by the oxidation of toluene or benzyl chloride. It occurs in white, light, feathery plates or needles, almost odourless when prepared synthetically, or with a slight, aromatic odour when obtained from benzoin, etc. It volatilises readily at a temperature much below its boiling-point, forming a feathery sublimate, and it is also slowly volatile in a current of steam, and in boiling benzene or other volatile liquid. A solution of 0.2 gramme neutralised with sodium hydroxide solution produces a buff-coloured precipitate with ferric chloride solution.

Soluble in water (1 in 450), boiling water (1 in 12), alcohol (1 in 3), ether (1 in 2.5), chloroform (1 in 7), and in fixed and volatile oils.

Standard, B.P.—Benzoic acid contains not less than 99.5 per cent. of $\text{C}_7\text{H}_6\text{O}_2$. Melting-point, 121° to 122° . Ash, not more than 0.05 per cent. Arsenic limit, 2 parts per million. Lead limit, 5 parts per million. It complies also with limit tests for chlorinated compounds, cinnamic acid, and for readily carbonisable substances.

Action and Uses.—Benzoic acid has an antiseptic action similar to that of salicylic acid; the presence of 0.1 per cent. of the free acid inhibits the growth of most bacteria. Taken **internally** it is rapidly absorbed and affects metabolism in the same way as do the salicylates; it combines with glycine and is excreted in the urine as hippuric acid. This action appears to be of the nature of a protective process since the hippurates are rapidly absorbed and have no toxic action. After the use of this drug, the urine contains less aromatic sulphate and indican, and this is regarded as evidence of diminished putrefaction in the intestine. It is used in chronic cystitis and other genito-urinary diseases to diminish the alkalinity and putridity of the urine, but unlike salicylic acid it has little influence on rheumatic diseases. Compound benzoic acid ointment is employed in the treatment of ring-worm of the scalp and body. The acid is sometimes **administered** in

cachets, but is better given in pills massed with glucose and tragacanth; for its local action on the throat as an expectorant and antiseptic, Trochisci Acidi Benzoici are suitable. When prescribed in mixtures the acid should be suspended with mucilage of tragacanth, or with syrup. The ammonium and sodium salts, however, are better for use in mixtures as they do not irritate the mucous membrane. For inhalation, the effect of benzoic acid is generally obtained by the use of compound tincture of benzoin which is of great service when inhaled with steam in the treatment of acute laryngitis and hoarseness.

Benzoic acid and benzoates may be used as preservatives in unfermented grape juice and non-alcoholic wine made from it, other sweetened or unsweetened non-alcoholic wines, cordials and fruit juices, sweetened mineral waters, brewed ginger beer, coffee extract, and pickles and sauces made from fruit or vegetables. The proportions, calculated as parts of benzoic acid per million, must not exceed those specified in the Public Health (Preservatives, etc., in Food) Regulations, 1925.

Dose.—0.3 to 1 gramme (5 to 15 grains).

BENZOYLIS PEROXIDUM.—Benzoyl peroxide, $C_6H_5 \cdot CO \cdot O_2 \cdot CO \cdot C_6H_5$, has been used in the form of a dusting powder and, mixed with soft paraffin, as an ointment in the treatment of burns and of dermatitis caused by poison ivy (*Rhus toxicodendron*).

METHYLIS ANTHRANILAS.—Methyl anthranilate, $C_6H_4NH_2 \cdot COOCH_3$, is the methyl ester of *o*-aminobenzoic acid, and is present in oil of neroli and other essential oils. It may be prepared synthetically from phthalic anhydride, and occurs as a crystalline solid melting at 24° . It is used in perfumery.

METHYLIS BENZOAS.—Methyl benzoate, or oil of niobe, $C_6H_5 \cdot COOCH_3$, may be prepared by esterifying benzoic acid with methyl alcohol. It occurs as a colourless liquid with a powerful odour, having a specific gravity of about 1.102 and a boiling-point of 199° . It is used in perfumery.

Preparations

Trochisci Acidi Benzoici, B.P.C.—(Troch. Acid. Benz.)—Benzoic Acid Lozenges. Each lozenge contains $\frac{1}{2}$ gram of benzoic acid.

This lozenge, containing 0.03 gramme of benzoic acid, was included in the British Pharmacopæia, 1911.

Unguentum Acidi Benzoici Compositum, B.P.C.—(Ung. Acid. Benz. Co.)—Compound Benzoic Acid Ointment. *Syn*—Whitfield's Ointment. Benzoic acid, 5 per cent., and salicylic acid, 3 per cent., in white soft paraffin and coconut oil.

ACIDUM BORICUM

(Acid. Boric.)

Boric Acid

Synonym—Boracic Acid.

Boric acid, $B(OH)_3$, may be obtained by the purification of native boric acid, or by the interaction of sulphuric acid and native borates.

It occurs in colourless, odourless, unctuous, shining scales or crystals, or in powder, with a sweetish after-taste. Boric acid is a weak acid and its alkali salts, which are hydrolysed, particularly in dilute solution, are alkaline. It volatilises in steam. On heating to 100° it loses water and is partly converted into metaboric acid, HBO_2 ; tetraboric (pyroboric) acid, $\text{H}_2\text{B}_4\text{O}_7$, is formed at 140° to 160° , and boric anhydride, B_2O_3 , at higher temperatures. Boric acid may be identified, and small amounts may be detected, by the pink colour imparted to turmeric paper which has been dipped in a solution slightly acidified with hydrochloric acid and dried; the colour changes to blue or greenish-black with solution of ammonia or of sodium hydroxide. An alcoholic solution burns with a flame tinged with green.

Soluble in water (1 in 25), boiling water (1 in 3), glycerin (1 in 4) and alcohol (1 in 30).

Standard, B.P.—Boric acid contains not less than 99.5 per cent. of H_3BO_3 . Arsenic limit, 5 parts per million. Lead limit, 25 parts per million. It complies also with tests for sulphate and for solubility in boiling alcohol.

Action and Uses.—Boric acid is a mild antiseptic; it inhibits the growth of putrefactive and saprophytic organisms, but does not destroy them. Taken internally, large doses cause gastro-intestinal irritation and smaller doses, over a long period, may exert a deleterious effect. The excretion of boric acid is very slow, so that it is cumulative. This, and the fact that it is without taste or odour, renders it the more dangerous. **Externally**, solutions of the acid are non-irritating and are used to wash out cavities after operations, and for application to wounds and ulcers; in the solid form it is employed as a dusting powder or for application to simple ulcers about the mouth and tongue. It may not be used freely with impunity since symptoms of poisoning from absorption sometimes occur. Several instances of fatal poisoning are on record from considerable quantities of solution having been left in body cavities.

Boric acid may be **administered** in cachets, in pastilles made with glycogelatin, or in mixtures flavoured with syrup of orange. It is prescribed with tincture of hyoscyamus and infusion of buchu. Aqueous solutions, sometimes more conveniently prepared from the crystals, are of service as mouth-washes, eye lotions and skin lotions, to allay irritation, as douches for irrigating the bladder and vagina, and as hot fomentations for ulcers, whitlows, boils and carbuncles. A saturated solution in alcohol may be used for instillation into the ear, and a simple solution in glycerin for painting the throat. Solutions may be sterilised by heating at 100° for thirty minutes, or by heating in an autoclave. The acid is also used as an antiseptic dusting powder, generally mixed with starch, zinc oxide, or talc; for this purpose, and for preparing ointments a very fine powder should be employed. Bougies, pessaries and suppositories containing boric acid may be prepared either with oil of theobroma or with glycerin suppository basis. The acid is also

used in the form of lint, gauze and wool. The use of boric acid as a food preservative is now prohibited.

Dose.—0·3 to 1 gramme (5 to 15 grains).

Preparations

Boroglycerinum, B.P.C.—(Boroglycer.)—Boroglycerin. A mixture of glyceryl borate, boric acid and glycerin containing the equivalent of about 50 per cent. w/w of boric acid.

Carbasus Acidi Borici, B.P.C.—(Carbas. Acid. Boric.)—Boric Acid Gauze. *Syn.*—Boric Gauze. It contains from 10 to 20 per cent. of boric acid.

Collyrium Acidi Borici, B.P.C.—(Collyr. Acid. Boric.)—Boric Acid Eye Lotion. Boric acid in distilled water, 1 in 50.

Collyrium Acidi Borici et Zinci, B.P.C.—(Collyr. Acid. Boric. et Zinc.)—Boric Acid and Zinc Eye Lotion. Each fluid ounce contains about 4 grains of boric acid and 1 grain of zinc sulphate in distilled water.

Glycerinum Acidi Borici, B.P.—(Glycer. Acid. Boric.)—Glycerin of Boric Acid. A mixture of glyceryl borate and glycerin, containing the equivalent of 31 per cent. w/w of boric acid, prepared by heating boric acid with glycerin. It contains less boric acid than boroglycerin. *Dose.*—0·6 to 2 millilitres (10 to 30 minims).

Gossypium Acidi Borici, B.P.C.—(Gossyp. Acid. Boric.)—Boric Acid Wool. *Syn.*—Boric Wool. It contains from 15 to 30 per cent. of boric acid.

Linteum Acidi Borici, B.P.C.—(Lint. Acid. Boric.)—Boric Acid Lint. *Syn.*—Boric Lint; Boracic Lint. It contains from 35 to 45 per cent. of boric acid.

Liquor Calcis Chlorinatæ cum Acido Borico, B.P.C.—(Liq. Calc. Chlorinat. c. Acid. Boric.)—Solution of Chlorinated Lime with Boric Acid. *Syn.*—Eusol. It contains when freshly prepared about 0·4 per cent. w/v of available chlorine.

Lotio Acidi Borici, B.P.C.—(Lot. Acid. Boric.)—Boric Acid Lotion. Boric acid, 1 in 30, in distilled water.

Oculentum Acidi Borici, B.P.C.—(Oculent. Acid. Boric.)—Boric Acid Eye Ointment. Boric acid, 4 per cent., in simple eye ointment.

Pulvis Acidi Borici et Amyli, B.P.C.—(Pulv. Acid. Boric. et Amyli)—Boric Acid and Starch Powder. Boric acid and starch, equal parts.

Pulvis Talcı Boricus, B.P.C.—(Pulv. Talc. Boric.)—Boric Talc Powder. *Syn.*—Talcum Boratum. Boric acid and starch, of each 1 in 10, with purified talc, perfumed with oil of geranium.

Pulvis Zinci et Acidi Borici, B.P.C.—(Pulv. Zinc. et Acid. Boric.)—Zinc and Boric Acid Powder. Zinc oxide and boric acid, equal parts.

Pulvis Zinci Sulphatis Compositus, B.P.C.—(Pulv. Zinc. Sulph. Co.)—Compound Zinc Sulphate Powder. *Syn.*—Pulvis Acidi Borici Compositus; Compound Boric Acid Powder; Pulvis Antisepticus Solubilis; Soluble Antiseptic Powder. Zinc sulphate, 12·5 per cent., with eucalyptol, menthol, phenol, salicylic acid, thymol and boric acid.

Unguentum Acidi Borici, B.P.—(Ung. Acid. Boric.)—Ointment of Boric Acid. *Syn.*—Boric Acid Ointment; Boracic Ointment. Boric acid 10 per cent., in white paraffin ointment.

Unguentum Acidi Borici Flavum, B.P.C.—(Ung. Acid. Boric. Flav.)—Yellow Boric Acid Ointment. Boric acid, 10 per cent., in yellow soft paraffin.

ACIDUM CAMPHORICUM

(Acid. Camph.)

Camphoric Acid

Camphoric acid, $\text{C}_8\text{H}_{14}(\text{COOH})_2$, may be prepared by oxidising camphor with nitric acid. It occurs in colourless, flaky crystals, or as a crystalline powder, with an acid, bitterish taste. Its solutions when neutralised give a yellowish-brown precipitate with ferric chloride and a light blue precipitate with copper sulphate.

Soluble in water (1 in 160), alcohol (1 in 1.5) and ether; only slightly soluble in chloroform.

Standard.—Camphoric acid contains not less than 99.5 per cent. of $\text{C}_{10}\text{H}_{16}\text{O}_4$. Melting-point, 185° to 187° . Ash, not more than 0.1 per cent.

Assay.—Dissolve about 0.4 gramme, accurately weighed, in 25 millilitres of alcohol and titrate with N/10 sodium hydroxide, using phenolphthalein as indicator; each millilitre of N/10 sodium hydroxide is equivalent to 0.01001 gramme of $\text{C}_{10}\text{H}_{16}\text{O}_4$.

Action and Uses.—Camphoric acid has a mild camphor-like action, and has been used for controlling the night-sweats of phthisis. Its anhidrotic action has been ascribed to stimulation of the respiratory centre. It may be **administered** in cachets or capsules, or in mixtures suspended with compound powder of tragacanth. When used as an anhidrotic the dose should be given two or three hours before bedtime. Camphoric acid is also employed in solution (0.2 to 5 per cent., with sufficient alcohol) as a local antiseptic for the nose and throat.

Dose.—0.5 to 2 grammes (8 to 30 grains).

ACIDUM CINNAMICUM

(Acid. Cinnam.)

Cinnamic Acid

Cinnamic acid, $\text{C}_6\text{H}_5\cdot\text{CH}:\text{CH}\cdot\text{COOH}$, may be obtained from storax, balsam of Peru, or balsam of tolu, or synthetically by the interaction of benzaldehyde, acetic anhydride and sodium acetate. It occurs in colourless, odourless, or slightly aromatic crystals, which are at first tasteless, but afterwards produce a burning sensation. On warming with potassium permanganate solution the odour of benzaldehyde is produced. It should be **stored** in well-closed, amber-coloured bottles.

Soluble in water (1 in 3500); more readily soluble in boiling water; freely soluble in alcohol.

Standard.—Cinnamic acid, determined by the method of the British Pharmacopœia for *Acidum Benzoicum*, contains not less than 99 per cent. of $C_9H_8O_2$; each millilitre of N/2 sodium hydroxide is equivalent to 0.07403 gramme of $C_9H_8O_2$. Melting-point, 132° to 135° . Ash, not more than 0.05 per cent. When 1 gramme is shaken with 100 millilitres of boiled and cooled water at 20° at intervals during one hour and filtered, 50 millilitres of the filtrate requires for neutralisation not more than 1.6 millilitres of N/10 sodium hydroxide, using phenolphthalein as indicator (limit of benzoic acid).

Action and Uses.—Cinnamic acid has an antiseptic action similar to that of benzoic acid. Its use by injection or by the mouth has been vaunted as a cure for tuberculosis, emphasis being laid on its power to induce leucocytosis; it is doubtful, however, if such an effect is produced in man. It is used chiefly as the sodium salt, since solutions of the acid give rise to some pain when injected hypodermically.

Dose.—0.12 to 0.2 gramme (2 to 3 grains); 0.0013 to 0.02 gramme ($\frac{1}{80}$ to $\frac{1}{5}$ grain), by injection.

BENZYLIS CINNAMAS.—Benzyl cinnamate, $C_6H_5 \cdot CH:CH \cdot COOCH_2 \cdot C_6H_5$, is the benzyl ester of cinnamic acid. A solution containing benzyl alcohol and ethyl cinnamate in olive oil corresponding to 5 per cent. of benzyl cinnamate is known as Jacobson's solution. It is given by intramuscular injection in doses of 0.5 to 1 millilitre (8 to 15 minims) in tuberculosis of the lungs and tuberculous glands and fistulæ.

SODII CINNAMAS.—Sodium cinnamate, $C_6H_5 \cdot CH:CH \cdot COONa$, occurs as a white, granular, amorphous powder or as a white, crystalline powder, having a faintly aromatic odour and a slightly alkaline reaction. It is soluble in water (1 in 11), alcohol (1 in 160), and in glycerin. It is a convenient form for administering cinnamic acid. Solutions for injection may be sterilised by tyndallisation or by filtration. Dose.—0.12 to 0.3 gramme (2 to 5 grains).

ACIDUM CITRICUM

(Acid. Cit.)

Citric Acid

Citric acid, $C_3H_4(OH)(COOH)_3 \cdot H_2O$, may be obtained from the juice of lemons and other fruits produced by species of *Citrus*, or prepared from glucose. It occurs in colourless, prismatic crystals, or as a white powder, efflorescent in warm dry air, and slightly hygroscopic in moist air. It is odourless and has a strongly acid taste. An 8 per cent. aqueous solution of the acid corresponds in strength to average samples of lemon juice. Citric acid begins to lose water at 75° ; at 135° it becomes anhydrous; it fuses at about 153° , and is decomposed into water and aconitic acid, $C_6H_4O_6$, at about 175° . On the gradual addition of potassium permanganate solution to an aqueous solution of citric acid which has been warmed with mercuric sulphate solution, the potassium permanganate is decolourised and a white precipitate is formed.

Soluble in water (10 in 6), alcohol (2 in 3) and glycerin (1 in 2); slightly soluble in ether.

Standard, B.P.—Citric acid contains not less than 99.5 per cent. and not more than the equivalent of 101 per cent. of $C_6H_8O_7 \cdot H_2O$. Ash, not more than 0.05 per cent. Arsenic limit, 1 part per million. Lead limit, 20 parts per million. It complies also with tests for tartaric acid and readily carbonisable matter, oxalic acid, sulphate, copper and iron.

Action and Uses.—Citric acid is partly absorbed from the alimentary canal and this portion is decomposed, being excreted by the kidneys in the form of sodium carbonate. It is used in dilute solution, in the form of lemon or lime juice, as a cooling drink in fevers. The alkali citrates increase the secretion of urine and render it less acid. For the administration of citric acid in the free state, lemon juice or syrup of lemon may be used. The value of lemon juice as a prophylactic and cure for scurvy is due to the presence of vitamin C, but orange juice is now preferred for this purpose (see *Succus Aurantii* and *Succus Limonis*). Citric acid is commonly **administered** in effervescing mixtures, in which it is directed to be added, in the form of powder or solution, to an alkaline mixture. Draughts prepared with a slight excess of acid are more agreeable; the following are the proportions necessary to form approximately neutral mixtures:—Citric acid, 10 parts, requires ammonium carbonate, about $7\frac{1}{2}$ parts, magnesium carbonate, about 7 parts, potassium bicarbonate, about $14\frac{1}{2}$ parts, and sodium bicarbonate, about 12 parts.

Dose.—0.3 to 2 grammes (5 to 30 grains).

ACIDUM FORMICUM

(Acid. Form.)

Formic Acid

Formic acid, $H\cdot COOH$, may be prepared by heating together glycerin and oxalic acid, or from the sodium formate produced by the action of carbon monoxide on sodium hydroxide or soda lime. It is a colourless liquid with a pungent odour and has a specific gravity of about 1.06. When warmed with solution of mercuric chloride, a white precipitate of mercurous chloride is formed. When dropped on cold concentrated sulphuric acid, carbon monoxide is evolved. Concentrated acids are also obtainable, containing about 50 per cent. and 85 to 90 per cent. of CH_2O_2 ; they are caustic liquids, which when applied to the skin cause painful burns.

Miscible in all proportions with water and alcohol.

Standard.—Formic acid contains not less than 24 per cent. and not more than 26 per cent. w/w of $H\cdot COOH$. Residue on evaporation on a

water-bath, not more than 0.01 per cent. 1 millilitre complies with the limit test for chlorides and with the limit test for sulphates. When neutralised with solution of sodium hydroxide no pungent or tarry odour develops (absence of acrolein and allyl formate). When 1 millilitre of the acid is mixed with 20 millilitres of water, heated on a water-bath with 6 grammes of yellow mercuric oxide for about fifteen minutes, shaking frequently, and the liquid filtered, the filtrate is not acid to litmus (limit of acetic acid).

Assay.—Dilute about 1 gramme, accurately weighed, to 100 millilitres with water. Take 20 millilitres of the solution and proceed as directed under *Calcii Formas*; each millilitre of N/10 potassium permanganate is equivalent to 0.002301 gramme of CH_2O_2 .

Action and Uses.—Formic acid resembles acetic acid in its action, but is more irritating and pungent. About one half of the formic acid taken internally is oxidised by the liver; the remainder is excreted as formates in the urine. The acid and its salts are employed internally as diuretics, and also in convalescence and debilitated conditions, and in cardiac weakness and muscular rheumatism, but there is lack of reliable evidence to show that they exert a tonic action upon muscle tissue. In cases of muscular rheumatism, formic acid and the formates have been injected intramuscularly, preceded by a small quantity of cocaine to alleviate the pain. The concentrated acid has been used with sodium bicarbonate in the preparation of an effervescent medicinal bath. Formic acid may be **administered** internally well diluted with water or alkaline aerated water, or as alkali formates.

Dose.—0.12 to 0.6 millilitre (2 to 10 minims).

Preparation

Syrupus Glycerophosphatum cum Formatibus, B.P.C.—(Syr. Glycerophosph. c. Format.)—Syrup of Glycerophosphates with Formates. *Syn.*—Compound Elixir of Glycerophosphates with Formates. Each fluid drachm contains $\frac{7}{8}$ grain of strychnine, about 1 grain of calcium glycerophosphate, $\frac{1}{2}$ grain each of potassium, sodium and magnesium glycerophosphates, $\frac{1}{4}$ grain of iron glycerophosphate and 3 grains each of potassium and sodium formates. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

ACIDUM GALLICUM

(Acid. Gall.)

Gallic Acid

Gallic acid is 3:4:5-trihydroxybenzoic acid, $\text{C}_6\text{H}_2(\text{OH})_3\cdot\text{COOH}, \text{H}_2\text{O}$, and is usually prepared by the hydrolysis of tannic acid. It occurs in white or pale brown, odourless, silky needles or prisms. Solutions reduce ammoniacal silver nitrate solution and give a white precipitate with potassium antimonyltartrate solution.

Soluble in water (1 in 100), boiling water (1 in 3), alcohol (1 in 8) and glycerin (1 in 10).

Standard.—Gallic acid loses, on drying at 100° , not more than 10 per cent. of its weight. Ash, not more than 0.1 per cent. A solution of 1 part of the acid in 20 parts of water is not more than faintly yellow, and gives no precipitate with albumen solution or gelatin solution (absence of tannic acid).

Action and Uses.—Gallic acid does not exert a local astringent action similar to that of tannic acid. It is absorbed and excreted as sodium gallate, but some of it is oxidised in the tissues. There is little evidence to justify its use in albuminuria, diabetes and the night-sweats of phthisis, or as a remote astringent in cases of internal hæmorrhage, for which purposes it has been employed. It is generally **administered** in mixture form, when it should be finely powdered and diffused without the aid of a suspending agent. It may also be given in cachets, powders, or pills (massed with about one-tenth of its weight of glycerin). Gallic acid is applied locally in the form of ointment. It is **incompatible** with preparations of ethyl nitrite and salts of iron.

Dose.—0.3 to 1 gramme (5 to 15 grains).

Preparation

Glycerinum Acidi Gallici, B.P.C.—(Glycer. Acid. Gall.)—Glycerin of Gallic Acid. About 1 in $6\frac{1}{2}$ w/w. Dose.—0.6 to 4 millilitres (10 to 60 minims).

ACIDUM GLYCEROPHOSPHORICUM

(Acid. Glycerophosph.)

Glycerophosphoric Acid

Synonyms—Glycerylphosphoric Acid; Monoglycerylphosphoric Acid.

Glycerophosphoric acid may be prepared by heating glycerin with phosphoric acid *in vacuo*. It occurs as a clear, colourless, odourless liquid, having an acid taste and containing about 20 per cent. w/w of $\text{C}_3\text{H}_5(\text{OH})_2\text{O}\cdot\text{PO}(\text{OH})_2$. It is a mixture of the isomeric α and β modifications; the proportions in which these two monoglycerides are present depend upon the method employed in its preparation; generally the chief constituent is the α variety, the salts of which are more soluble than those of the β acid. When heated with water, glycerophosphoric acid is decomposed into glycerin and phosphoric acid. It is used chiefly in the form of its salts, calcium and sodium glycerophosphates being the more important. Stronger solutions of the acid, namely, 25 per cent. (specific gravity, about 1.13) and 50 per cent. (specific gravity, about 1.30) are also obtainable.

Miscible in all proportions with water and alcohol.

Standard.—Glycerophosphoric acid contains not less than 19 and

not more than 21 per cent. w/w of $C_3H_9O_6P$. Specific gravity, 1.095 to 1.105. Arsenic limit, 2.5 parts per million. Lead limit, 10 parts per million. Dilute 2 millilitres with 50 millilitres of water and add 5 millilitres of dilute sulphuric acid; the mixture, after standing for thirty minutes, shows no turbidity (limit of barium). Neutralise 5 grammes with sodium hydroxide solution and mix thoroughly in a stoppered cylinder with 20 millilitres of dehydrated alcohol, add 5 grammes of recently ignited calcium sulphate, shake until the supernatant liquid is practically clear, filter into a 100 millilitre beaker, wash the residue in the cylinder with a few millilitres of dehydrated alcohol, evaporate the filtrate and washings, dry the residue at 70° for one hour and weigh; the residue weighs not more than 0.1 gramme (limit of free glycerin). Limit of combined alkali (calculated as Na_2O), 0.4 per cent.; limit of free phosphate (calculated as P_2O_5), 0.5 per cent.

Assay.—Dilute 5 grammes with a little water and titrate with N/1 sodium hydroxide, using bromocresol green as indicator; repeat the titration on another 5 grammes using thymol blue as indicator. When the titration with thymol blue is greater than twice the titration with bromocresol green, the difference gives the combined alkali present; each millilitre of N/1 sodium hydroxide is equivalent to 0.031 gramme of Na_2O . To the solution titrated to thymol blue add 40 millilitres of 30 per cent. w/v calcium chloride solution (neutral to thymol blue), boil for five minutes, cool and titrate with N/1 sodium hydroxide; the volume required represents the free phosphate present; each millilitre of N/1 sodium hydroxide is equivalent to 0.071 gramme of P_2O_5 . The difference between the titrations with bromocresol green and thymol blue, after deducting the volume required for any free phosphate, represents the proportion of glycerophosphoric acid present; each millilitre of N/1 sodium hydroxide is equivalent to 0.17208 gramme of $C_3H_9O_6P$.

Action and Uses.—Glycerophosphoric acid and its salts were introduced into medicine on the supposition that they remedy a deficiency of phosphorus in the brain, especially in nervous diseases. This speculation is not supported by facts, since the phosphate in the compound can be recovered from the urine. The acid and its salts are supposed to act as nerve tonics and their use has been advocated in all kinds of nervous and wasting diseases. This supposition may have arisen from the fact that the acid can be prepared by hydrolysis of lecithin, which occurs in brain and nerve tissue generally, and has been described as exerting a beneficial action on growth. After absorption, the glycerophosphates slightly increase the metabolism of the body, like most inorganic salts. Compounds of casein with free glycerophosphoric acid may be **administered** in aqueous solution; but more generally the acid is given in combination with sodium, potassium, calcium, magnesium, iron, manganese or quinine. These salts, in various combinations and proportions, are prescribed in syrups and similar preparations and also in solution for intramuscular injection.

Dose.—0.3 to 0.6 millilitre (5 to 10 minims).

Preparations

Caseinum Glycerophosphaticum, B.P.C.—(Casein. Glycerophosph.)—Glycerophosphated Casein. Soluble casein, with sodium and calcium glycerophosphates, of each, 1 in 40. Dose.— 4 to 16 grammes (1 to 4 drachms).

Emulsio Olei Morrhue cum Glycerophosphatibus, B.P.C.—(Emuls. Ol. Morrh. c. Glycerophosph.)—Emulsion of Cod-liver Oil with Glycerophosphates. It contains 50 per cent. v/v of cod-liver oil, with the glycerophosphates of calcium, magnesium, iron, sodium and potassium. Dose.— 8 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Emulsio Paraffini Liquidi cum Glycerophosphatibus, B.P.C.—(Emuls. Paraff. Liq. c. Glycerophosph.)—Emulsion of Liquid Paraffin with Glycerophosphates. *Syn.*—Emulsio Petrolei cum Glycerophosphatibus; Emulsion of Petroleum with Glycerophosphates. It contains 50 per cent. v/v of liquid paraffin with the glycerophosphates of calcium, magnesium, iron, sodium and potassium. Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

Extractum Malti Liquidum cum Glycerophosphatibus, B.P.C.—(Ext. Malt. Liq. c. Glycerophosph.)—Liquid Extract of Malt with Glycerophosphates. Each fluid drachm contains the equivalent of $\frac{1}{2}$ grain of potassium glycerophosphate and $\frac{1}{2}$ grain of sodium glycerophosphate in liquid extract of malt. Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

Glycerinum Glycerophosphatum Compositum, B.P.C.—(Glycer. Glycerophosph. Co.)—Compound Glycerin of Glycerophosphates. *Syn.*—Elixir Glycerophosphatum; Elixir of Glycerophosphates; Glycerol Glycerophosphatis. Each fluid drachm contains calcium glycerophosphate, $1\frac{1}{2}$ grains; potassium, sodium and magnesium glycerophosphates, of each, about $\frac{1}{2}$ grain; iron glycerophosphate, about $\frac{1}{2}$ grain; with glycerophosphoric acid, solution of bordeaux B orange-flower water, cherry-laurel water, glycerin and double chloroform water. Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

Glycerinum Glycerophosphatum cum Medulla Rubra, B.P.C.— (Glycer. Glycerophosph. c. Medull. Rub.)—Glycerin of Glycerophosphates with Red Bone Marrow. *Syn.*—Elixir Glycerophosphatum cum Medulla Rubra; Elixir of Glycerophosphates with Red Bone Marrow; Glycerol Glycerophosphatis cum Medulla Rubra. Equal parts of compound glycerin of glycerophosphates and extract of red bone marrow. Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

Syrupus Glycerophosphatum Compositus, B.P.C.—(Syr. Glycerophosph. Co.)—Compound Syrup of Glycerophosphates. *Syn.*—Syrupus Glycerophosphatum Ruber. Each fluid drachm contains $\frac{1}{80}$ grain of strychnine, $1\frac{1}{2}$ grains of calcium glycerophosphate, about $\frac{1}{2}$ grain each of potassium, sodium and magnesium glycerophosphates and about $\frac{1}{2}$ grain each of iron glycerophosphate and caffeine. Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

Syrupus Glycerophosphatum Compositus cum Medulla Rubra, B.P.C.—(Syr. Glycerophosph. Co. c. Medull. Rub.)—Compound Syrup of Glycerophosphates with Red Bone Marrow. Equal parts of compound syrup of glycerophosphates and extract of red bone marrow. Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

Syrupus Glycerophosphatum cum Formatibus, B.P.C.—(Syr. Glycerophosph. c. Format.)—Syrup of Glycerophosphates with Formates. *Syn.*—Compound Elixir of Glycerophosphates with Formates. Each fluid drachm contains $\frac{1}{80}$ grain of strychnine, about 1 grain of calcium glycerophosphate, $\frac{1}{2}$ grain each of potassium, sodium and magnesium glycerophosphates, $\frac{1}{2}$ grain of iron glycerophosphate and 3 grains each of potassium and sodium formates. Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

Syrupus Glycerophosphatum et Pepsini Compositus, B.P.C.—(Syr. Glycerophosph. et Pepsin. Co.)—Compound Syrup of Glycerophosphates and Pepsin. *Syn.*—Syrupus Glycerophosphatum Compositus (Robin). Each fluid drachm contains $1\frac{1}{2}$ grains of calcium glycerophosphate, about $\frac{1}{2}$ grain each of pepsin and of magnesium, sodium and potassium glycerophosphates, and about $\frac{1}{2}$ grain

of iron glycerophosphate, with *caffeine* and tincture of *ignatia*. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Syrupus Glycerophosphatum Flavus, B.P.C.—(Syr. Glycerophosph. Flav.)—Yellow Syrup of Glycerophosphates. It is of the same strength as compound syrup of glycerophosphates, but contains no strychnine and is coloured yellow. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

ACIDUM HYDRIODICUM DILUTUM

(Acid. Hydriod. Dil.)

Dilute Hydriodic Acid

HI = 127·9

Dilute hydriodic acid may be obtained by the action of hydrogen sulphide on a solution of iodine, or by the action of phosphorus on iodine in the presence of water in an atmosphere of carbon dioxide, and subsequent dilution. It is a clear, colourless, odourless liquid with an acid taste and contains about 10 per cent. w/w of HI with 1 per cent. w/w of hypophosphorous acid, added to prevent discolouration on keeping. It should be **stored** in small, well-filled, amber-coloured, glass-stoppered bottles protected from light. Hydriodic acids of greater concentrations can be obtained, including a constant boiling acid containing approximately 57 per cent. w/w of HI and boiling at 125°.

Standard.—Dilute hydriodic acid contains not less than 9·8 per cent. and not more than 10·2 per cent. w/w of HI. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. 5 millilitres complies with the limit test for sulphates. To 10 millilitres add 1 millilitre of dilute sulphuric acid; no turbidity is produced within five minutes (limit of barium).

Assay.—Dilute about 5 grammes, accurately weighed, with water, add an excess of N/10 silver nitrate, 5 millilitres of nitric acid and 0·5 millilitre of ferric ammonium sulphate solution; titrate with N/10 ammonium thiocyanate until a permanent pink colour is produced; each millilitre of N/10 silver nitrate is equivalent to 0·01279 gramme of HI.

Action and Uses.—Dilute hydriodic acid has the general properties of iodine in weak combination. It is administered chiefly in the form of Syrupus Acidi Hydriodici when the alkali iodides are unsuitable, and is specially suitable for children. It is **incompatible** with alkalis and oxidising agents.

Dose.—0·3 to 0·6 millilitre (5 to 10 minims), well diluted.

Preparation.

Syrupus Acidi Hydriodici, B.P.C.—(Syr. Acid. Hydriod.)—Syrup of Hydriodic Acid. Dilute hydriodic acid, 10 per cent. v/v, with distilled water and syrup. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This syrup was included in the British Pharmacopæia, 1914.

ACIDUM HYDROBROMICUM

(Acid. Hydrobrom.)

Hydrobromic Acid $\text{HBr} = 80.92$

Hydrobromic acid may be prepared by the action of bromine on amorphous phosphorus in the presence of water, and distilling the hydrobromic acid at a moderate heat from the phosphorous acid thus formed. It occurs as a colourless or light straw-coloured liquid having a strong, acid smell and contains about 34.5 per cent. w/w of hydrogen bromide. When 290 grammes is diluted with 710 grammes of water, a dilute acid containing approximately 10 per cent. w/w of HBr is obtained. Acids of the following strengths are also found in commerce:—25 per cent. w/w of HBr equivalent to 30.2 per cent. w/v (specific gravity, 1.208), 30 per cent. w/w equivalent to 37.8 per cent. w/v (specific gravity, 1.260), 40 per cent. w/w equivalent to 55.0 per cent. w/v (specific gravity, 1.375). When hydrobromic acid is distilled it yields a constant boiling mixture containing approximately 49 per cent. w/w of hydrogen bromide and boiling at about 125° .

Standard.—Hydrobromic acid, determined by the method of the British Pharmacopœia for Acidum Hydrobromicum Dilutum, contains not less than 34 per cent. and not more than 35 per cent. w/w of HBr. Specific gravity, 1.303 to 1.314. When diluted as described above it yields a dilute acid which complies with the tests for purity for Acidum Hydrobromicum Dilutum.

Uses.—Concentrated hydrobromic acid may be employed for the preparation of Acidum Hydrobromicum Dilutum.

ACIDUM HYDROBROMICUM DILUTUM

(Acid. Hydrobrom. Dil.)

Dilute Hydrobromic Acid $\text{HBr} = 80.92$

Dilute hydrobromic acid may be obtained by the interaction of bromine and sulphurous acid, or by the action of bromine on phosphorus in the presence of water, with subsequent distillation, or by distilling potassium bromide and phosphoric acid. It may be prepared by diluting Acidum Hydrobromicum with the requisite quantity of water (see Acidum Hydrobromicum). It occurs as a clear, colourless, odourless, acid liquid. Fothergill's hydrobromic acid, prepared by mixing aqueous solutions of potassium bromide and tartaric acid, contains less than 10 per cent. of hydrobromic acid with a small quantity of potassium acid tartrate. Dilute hydrobromic acid should be **stored** in amber-coloured, glass-stoppered bottles, and protected from light.

Standard, B.P.—Dilute hydrobromic acid contains not less than 9·8 per cent. and not more than 10·2 per cent. w/w of HBr. Specific gravity, 1·072 to 1·075. Residue on evaporation on a water-bath, not more than 0·01 per cent. w/w. Arsenic limit, 5 parts per million. Lead limit, 5 parts per million. It complies also with limit tests for barium, sulphite, chloride and sulphate.

Action and Uses.—Dilute hydrobromic acid is said to be less depressing than the bromides, and to give rise to bromism less frequently; in reality it is a question of dosage, for the number of bromine ions contained in an average dose of hydrobromic acid is considerably smaller than that contained in an average dose of sodium or potassium bromide. The acid is sometimes given with quinine to prevent cinchonism, although its use for this purpose cannot be relied upon.

Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

Preparation

Mistura Chloroformi Composita, B.P.C.—(Mist. Chlorof. Co.)—Compound Chloroform Mixture. *Syn.*—Mistura Tussi Sedativa; Mistura Tussi Rubra. Each fluid drachm contains 15 minims of dilute hydrobromic acid and $\frac{1}{10}$ grain of morphine hydrochloride with chloroform, solution of bordeaux B, cherry-laurel water, syrup of tolu and syrup. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

ACIDUM HYDROCHLORICUM

(Acid. Hydrochlor.)

Hydrochloric Acid

HCl = 36·46

Hydrochloric acid may be prepared by saturating water with hydrogen chloride evolved by the action of sulphuric acid on sodium chloride. It occurs as a colourless, fuming liquid with a pungent odour. When distilled it yields a constant boiling mixture which boils at 110° and contains approximately 20 per cent. w/w of hydrogen chloride. Impure, commercial hydrochloric acid is popularly known as “spirits of salts” and also as muriatic acid.

Standard, B.P.—Hydrochloric acid contains not less than 31 per cent. and not more than 33 per cent. w/w of HCl. Specific gravity, 1·158 to 1·168. Residue on evaporation and gentle ignition, not more than 0·01 per cent. w/w. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. It complies also with limit tests for free chlorine, bromide, iodide, sulphite and sulphate.

Action and Uses.—Hydrochloric acid is a powerful caustic; it does not penetrate the tissues so deeply as does sulphuric or nitric acid, but produces a white eschar which afterwards sloughs. The strong acid is rarely used in therapeutics. Dilute hydrochloric acid in the mouth

induces a reflex flow of saliva and is thus of value in fevers and in other conditions where it is desired to allay thirst. It is used in those conditions in which there is commonly some deficiency of the normal hydrochloric acid of the gastric juice, such as cancer of the stomach and primary anæmias. In the duodenum the dilute acids induce the formation of secretin, a body which augments the flow of pancreatic juice. Hydrochloric acid is neutralised before absorption, and necessarily reduces the alkalinity of the tissues. There is an increase of ammonia nitrogen and a decrease of urea excreted in the urine. Applied to the skin dilute hydrochloric acid is a mild astringent.

Dilute hydrochloric acid is used in stomachic and digestive mixtures, cooling lotions and astringent gargles. In the treatment of achlorhydria associated with pernicious anæmia as much as 8 millilitres (2 fluid drachms) of dilute hydrochloric acid, well diluted with water, may be given. In cases of **poisoning** by hydrochloric acid, emetics and gastric lavage should not be used, but large draughts of water containing sodium bicarbonate, magnesia, chalk or soap, or preparations such as mixture of magnesium hydroxide or saccharated solution of calcium hydroxide should be given, followed by the usual methods of preventing collapse.

BETAINE HYDROCHLORIDUM.—Betaine hydrochloride is the hydrochloride of trimethyl glyccoll, a base occurring in sugar-beet and obtained from sugar-beet molasses. It occurs as a white crystalline substance readily soluble in water, giving a strongly acid solution, and is used for the administration of hydrochloric acid in a solid form. Dose.—0·06 to 0·5 gramme (1 to 8 grains).

Preparation

Acidum Hydrochloricum Dilutum, B.P.—(Acid. Hydrochlor. Dil.)—Dilute Hydrochloric Acid. It contains 10 per cent. w/w of HCl (limits, 9·5 to 10·5). Specific gravity, 1·045 to 1·052. It complies also with the tests for purity under Acidum Hydrochloricum when three times the quantity is taken for each test. Dose.—0·3 to 4 millilitres (5 to 60 minims).

ACIDUM HYDROCYANICUM DILUTUM

(Acid. Hydrocyan. Dil.)

Dilute Hydrocyanic Acid

Synonym—Dilute Prussic Acid.

Dilute hydrocyanic acid is an aqueous solution of hydrogen cyanide, HCN, which may be prepared by distilling potassium ferrocyanide with dilute sulphuric acid. It occurs as a colourless liquid, with a characteristic odour and a specific gravity of about 0·997. It should be **stored** in small, glass-stoppered bottles, inverted, in a cool place and protected from light.

Standard, B.P.—Dilute hydrocyanic acid contains not less than 1·9 per cent. and not more than 2·1 per cent. w/w of HCN. Residue on

evaporation, not more than 0.02 per cent. It complies also with a limit test for sulphate. Acidum Hydrocyanicum Dilutum I.A. contains 2 per cent. of hydrocyanic acid.

Action and Uses.—Dilute hydrocyanic acid is a powerful poison to all forms of living tissue. It is absorbed with great rapidity, and in lethal doses paralyzes respiration and the heart. One of the first effects of the acid is to excite the medulla powerfully, especially the respiratory centre. Taken **internally** it is employed for its sedative action on the stomach in the vomiting of pregnancy, and other forms of vomiting. It is of doubtful value in the treatment of cough. On account of its depressing effect on sensory nerve endings it is used **externally** in dilute solution (about 1 in 20) for application to the unbroken skin to relieve irritation and itching in such conditions as lichen and urticaria.

In cases of **poisoning** by hydrocyanic acid, death generally occurs within one or two minutes, but, when this is not the case, artificial respiration should be resorted to, and the following mixture given as an antidote:—0.6 gramme (10 grains) of ferrous sulphate, 4 millilitres (1 fluid drachm) of solution of ferric chloride, and 30 millilitres (1 fluid ounce) of water, followed by 1.2 grammes (20 grains) of potassium carbonate, dissolved in 30 millilitres (1 fluid ounce) of water. Ammonia (inhaled and internally) and brandy should also be given as stimulants; atropine, $\frac{1}{80}$ grain, may be given hypodermically and 50 millilitres of a 20 per cent. solution of sodium thiosulphate intravenously may be tried. Intravenous injection of 50 millilitres of a 1 per cent. solution of methylene blue has been reported to be successful in some cases.

Dose.—0.12 to 0.3 millilitre (2 to 5 minims).

ACIDUM HYDROCYANICUM FORTIUS

(Acid. Hydrocyan. Fort.)

Stronger Hydrocyanic Acid

HCN = 27.02

Synonym—Scheele's Hydrocyanic (or Prussic) Acid.

Stronger hydrocyanic acid is an aqueous solution of hydrogen cyanide, containing approximately 4 per cent. w/w of HCN. It may be prepared by distilling potassium ferrocyanide with dilute sulphuric acid. It occurs as a colourless liquid with a characteristic odour. The vapour when inhaled is extremely poisonous. Specific gravity, about 0.994. The aqueous solution is unstable and slowly undergoes hydrolysis with formation of ammonium formate. It should be **stored** in a cool, dark place, in small, green or blue bottles, inverted, with well-fitting stoppers tied over with impervious tissue.

Standard.—Stronger hydrocyanic acid, determined by the method of the British Pharmacopœia for Acidum Hydrocyanicum Dilutum,

contains not less than 3·8 per cent. and not more than 4·2 per cent. w/w of HCN. When diluted with an equal volume of water it complies with the tests for purity for Acidum Hydrocyanicum Dilutum.

Uses.—Stronger hydrocyanic acid is employed chiefly for poisoning animals. It is seldom used in medicine except for the preparation of dilute hydrocyanic acid.

ACIDUM HYDROFLUORICUM

(Acid. Hydrofluor.)

Hydrofluoric Acid

$\text{HF} = 20\cdot01$.

Synonym—Fluoric Acid.

Hydrofluoric acid may be prepared by the action of sulphuric acid on fluorspar. The gas produced is dissolved in water, and the solution adjusted to contain about 40 per cent. w/w of hydrogen fluoride. It occurs as a colourless, fuming liquid which attacks glass strongly. The crude acid contains sulphuric, sulphurous and fluosilicic acids; for use in medicine and as a chemical reagent the acid must be purified by redistillation. The constant boiling acid contains approximately 37 per cent. w/w of hydrogen fluoride and boils at 120° . Crude hydrofluoric acid of various strengths up to 55 per cent. is prepared for technical purposes. Hydrofluoric acid should be **stored** in gutta-percha or vulcanite bottles, or preferably in bottles coated internally with ceresin or hard paraffin.

Action and Uses.—Hydrofluoric acid and the alkali fluorides are powerful antiseptics. When taken internally, hydrofluoric acid is absorbed in the merest traces only; it causes death by shock following acute gastro-enteritis. The fluorides of sodium and ammonium have been employed internally in goitre, phthisis, and enlarged spleen, but their value is extremely doubtful. Unless well diluted, when taken internally the acid exerts an extremely powerful local irritant effect, and may destroy the mucous membrane. For internal **administration** Acidum Hydrofluoricum Dilutum containing about 0·5 per cent. of the strong acid in distilled water may be given in doses of 0·3 to 1 millilitre (5 to 15 minims), well diluted. The strong acid diluted five times has been used as an inhalation in phthisis; the eyes should be well protected from the vapour. Hydrofluoric acid is an extremely powerful corrosive. The greatest care should be taken to prevent it from coming into contact with the skin, since it may produce exceedingly painful and slow-healing sores after even a momentary contact. Burns produced by hydrofluoric acid may be treated by baths of ammonium carbonate or sodium carbonate.

ACIDUM HYPOPHOSPHOROSUM

(Acid. Hypophosph.)

Hypophosphorous Acid

Hypophosphorous acid may be prepared by dissolving barium hypophosphite in hot distilled water and slowly adding dilute sulphuric acid, continuing the addition of acid, drop by drop, until no further turbidity is produced. The mixture is set aside in a warm place for one hour, filtered, the precipitate washed with hot water until the washings have no longer an acid reaction, and the filtrate evaporated on a water-bath until its specific gravity is about 1.14. It occurs as a colourless, odourless, acid liquid and contains about 31 per cent. w/w of H_3PO_2 . The acid is monobasic. Solutions yield with mercuric chloride solution a white precipitate which becomes grey on adding excess of the acid; with copper sulphate solution a red precipitate of cuprous hydride is produced. When 323 grammes is diluted with 677 grammes of water, a dilute acid containing approximately 10 per cent. w/w of H_3PO_2 is obtained.

Standard.—Hypophosphorous acid, determined by the method of the British Pharmacopœia for Acidum Hypophosphorosum Dilutum, contains not less than 30 per cent. and not more than 32 per cent. w/w of H_3PO_2 . When diluted with water as described above it yields a dilute acid which complies with the tests for purity for Acidum Hypophosphorosum Dilutum.

Uses.—Hypophosphorous acid may be employed for the preparation of Acidum Hypophosphorosum Dilutum.

ACIDUM HYPOPHOSPHOROSUM DILUTUM

(Acid. Hypophosph. Dil.)

Dilute Hypophosphorous Acid

Dilute hypophosphorous acid may be obtained by treating barium hypophosphite with dilute sulphuric acid or by diluting Acidum Hypophosphorosum with the requisite amount of water (see Acidum Hypophosphorosum). It occurs as a clear, colourless, odourless, acid liquid, miscible with water and with alcohol, and yields the reactions described under hypophosphorous acid.

Standard, B.P.—Dilute hypophosphorous acid contains not less than 9.8 per cent. and not more than 10.2 per cent. w/w of H_3PO_2 . Specific gravity, 1.040 to 1.042. Arsenic limit, 2 parts per million. Lead limit, 5 parts per million. It complies also with limit tests for barium, phosphoric and oxalic acids, chloride, sulphate and iron.

Action and Uses.—Hypophosphorous acid is rapidly absorbed after neutralisation and the whole of the quantity administered can be recovered from the urine. It is **administered** usually in the form of its salts. It has been asserted that hypophosphorous acid exerts an action on nutrition resembling that of phosphorus, and its salts are therefore sometimes prescribed in wasting diseases such as phthisis. There is no pharmacological evidence to show that they behave differently from other inorganic salts, and any benefit derived is ascribed to the iron or calcium with which the acid may be combined. Hypophosphorous acid is employed in the preparation of syrup of ferrous iodide to prevent oxidation.

Dose.—0.3 to 1 millilitre (5 to 15 minims).

Preparations

Emulsio Olei Morrhue cum Hypophosphitibus, B.P.C.—(Emuls. Ol. Morrh. c. Hypophosph.)—Emulsion of Cod-liver Oil with Hypophosphites. *Syn.*—Emulsio Olei Morrhue Composita; Compound Emulsion of Cod-liver Oil. It contains 50 per cent. v/v of cod-liver oil with 1 grain each of the hypophosphites of calcium and sodium in each fluid drachm. Dose.—8 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Emulsio Paraffini Liquidi cum Hypophosphitibus, B.P.C.—(Emuls. Paraff. Liq. c. Hypophosph.)—Emulsion of Liquid Paraffin with Hypophosphites. *Syn.*—Emulsio Petrolei cum Hypophosphitibus; Emulsion of Petroleum with Hypophosphites. It contains 50 per cent. v/v of liquid paraffin with 1 grain each of the hypophosphites of calcium and sodium in each fluid drachm. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Extractum Malti Liquidum cum Hypophosphitibus, B.P.C.—(Ext. Malt. Liq. c. Hypophosph.)—Liquid Extract of Malt with Hypophosphites. Each fluid drachm contains $\frac{1}{2}$ grain each of the hypophosphites of calcium and sodium in liquid extract of malt. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Glycerinum Hypophosphitum Compositum, B.P.C.—(Glycer. Hypophosph. Co.)—Compound Glycerin of Hypophosphites. *Syn.*—Glycerol Hypophosphitis. Each fluid drachm contains calcium hypophosphite and potassium hypophosphite, of each, about 1 grain; manganese hypophosphite and quinine (as hypophosphite), of each, about $\frac{1}{2}$ grain; strychnine (as hypophosphite), about $\frac{1}{10}$ grain; with solution of ferric hypophosphite, hypophosphorous acid, distilled water and glycerin. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Syrupus Hypophosphitum Compositus, B.P.C.—(Syr. Hypophosph. Co.)—Compound Syrup of Hypophosphites. *Syn.*—Syrupus Ferri Hypophosphitis Compositus; Compound Syrup of Iron Hypophosphite. Each fluid drachm contains $\frac{1}{10}$ grain of strychnine, $\frac{1}{2}$ grain of quinine, $\frac{1}{2}$ grain of calcium hypophosphite and $\frac{1}{2}$ grain each of manganese and potassium hypophosphites. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Syrupus Triplex, B.P.C.—(Syr. Trip.)—Triple Syrup. Equal parts of compound syrup of ferrous phosphate, compound syrup of hypophosphites and syrup of ferrous phosphate with quinine and strychnine. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tabellæ Hypophosphitum Compositæ, B.P.C.—(Tab. Hypophosph. Co.)—Compound Tablets of Hypophosphites. Each tablet contains the hypophosphites of calcium, manganese, potassium, iron and quinine, and strychnine, and is equivalent to 1 fluid drachm of compound syrup of hypophosphites. Dose.—1 or 2 tablets.

Tabellæ Phosphatæ et Hypophosphitæ Compositæ, B.P.C.—(Tab. Phosph. et Hypophosph. Co.)—Compound Tablets of Phosphates and Hypophosphites. *Syn.*—Triple Syrup Tablets. Each tablet contains saccharated iron phosphate, calcium, potassium and sodium phosphates, calcium, manganese, potassium and iron hypophosphites, strychnine and quinine sulphate, and is equivalent to 1 fluid drachm of a mixture of equal volumes of compound syrup of hypophosphites, compound syrup of ferrous phosphate and syrup of ferrous phosphate with quinine and strychnine. Dose.—1 tablet.

ACIDUM LACTICUM

(Acid. Lact.)

Lactic Acid

Lactic acid may be obtained by the lactic fermentation of sugar, and consists of a mixture of lactic acid, $\text{CH}_3\cdot\text{CH}(\text{OH})\cdot\text{COOH}$, and lactide, $\text{C}_6\text{H}_8\text{O}_4$. It occurs as a colourless, syrupy, hygroscopic liquid with a strongly acid reaction and a sour taste; it is odourless or may sometimes possess a slight, but not unpleasant, odour. When warmed with one tenth of its weight of potassium permanganate, acetaldehyde is evolved.

Miscible in all proportions with water, alcohol (90 per cent.) and ether; almost insoluble in chloroform.

Standard, B.P.—Lactic acid contains the equivalent of not less than 87.5 per cent. w/w of $\text{C}_3\text{H}_5\text{O}_3$. Specific gravity, about 1.21. Ash, not more than 0.1 per cent. w/w. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. It complies also with limit tests for various sugars, chloride, sulphate and iron.

Action and Uses.—Lactic acid is **administered** in mixtures in the form of the dilute acid, often with iron and calcium lactates, in the treatment of atonic dyspepsia. It is employed as a caustic to destroy tuberculous ulcerations of the pharynx and larynx and also as a local application to lupus and to diphtheritic membranes (1 in 15). A 1 in 3 dilution has been recommended as an application in alopecia. Nascent lactic acid has also been employed as an intestinal antiseptic. For this purpose living lactic acid-forming bacilli are ingested with suitable material for their growth and multiplication (see Lac Coactum).

In the preparation of acidified milk, lactic acid is added to whole milk in the proportion of from 45 to 60 minims to the pint. The acid should be added drop by drop to cold milk, stirring vigorously to prevent the formation of large curds. A fine flocculent curd results which will flow through an ordinary rubber teat. Sugar or honey is now added. After the addition of the acid, the milk must not be boiled or unduly heated or thick clots will form. This method is now considered by many to be the best routine procedure if the breast is not available. The procedure can also be adopted in the case of dried

milk, either full-cream or half-cream. A 10 per cent. dilution of lactic acid is used as a vaginal douche in leucorrhœa. Lactic acid, 1 to 2 per cent., in the form of jelly or pessaries in combination with boric acid is employed as a contraceptive.

Dose.—0·3 to 1·2 millilitres (5 to 20 minims).

ÆTHYLIS LACTAS.—Ethyl lactate, $\text{CH}_3\text{CH}(\text{OH})\text{C}(\text{OOC}_2\text{H}_5)_2$, may be prepared by the esterification of lactic acid. The pure substance is a colourless and almost odourless liquid, but the commercial variety usually has a somewhat disagreeable odour. It has a specific gravity of 1·03 to 1·04, and a boiling-range of about 135° to 160° . It is miscible with water and with aromatic hydrocarbons and is used as a solvent in the manufacture of lacquers and varnishes.

Preparations

Acidum Lacticum Dilutum, B.P.C.—(Acid. Lact. Dil.)—Dilute Lactic Acid. It contains about 15 per cent. v/v of lactic acid. **Dose.**—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Syrupus Acidi Lactici, B.P.C.—(Syr. Acid. Lact.)—Syrup of Lactic Acid. Lactic acid, 2·5 per cent v/v, in syrup. **Dose.**—4 to 8 millilitres (1 to 2 fluid drachms).

ACIDUM NITRICUM

(Acid. Nit.)

Nitric Acid

$\text{HNO}_3 = 63\cdot02$

Nitric acid may be obtained by the distillation of sodium nitrate with sulphuric acid. It occurs as a clear, colourless, or almost colourless, liquid which evolves corrosive fumes and boils at 121° . Other strengths of nitric acid are also obtainable in commerce. Fuming nitric acid has a specific gravity of 1·5 and contains about 94 per cent. w/w of HNO_3 ; it is usually of a reddish-brown colour owing to the presence of dissolved oxides. Aqua Regia is a mixture of concentrated hydrochloric and nitric acids.

Standard, B.P.—Nitric acid contains not less than 69 and not more than 71 per cent. w/w of HNO_3 . Specific gravity, about 1·42. Residue on evaporation and gentle ignition, not more than 0·01 per cent. w/w. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. It complies also with limit tests for copper, zinc, iron, chloride and sulphate.

Action and Uses.—Nitric acid is a powerful caustic owing to its oxidising power and its coagulating effect upon albumin. The coagulated albumin is insoluble in excess of the acid, and for this reason its caustic action is localised to some extent; it forms a convenient means of removing warts, but should be used with caution. Nitric acid is **administered** as Acidum Nitricum Dilutum in mixtures with vegetable bitters for gastric indigestion and stomatitis; it is prescribed as an astringent, often with opium, for some forms of diarrhœa.

Externally, the dilute acid may be employed further diluted (1 in 10) to relieve itching in lichen, prurigo, etc., and has an action similar to other dilute acids.

In cases of **poisoning** by nitric acid, large draughts of soap and water should be taken at once with calcium or magnesium hydroxide, well diluted; shock should be treated in the usual way. The fumes of nitric acid are irritating and corrosive to the respiratory passages; they may cause severe symptoms reflexly from the nasal and bronchial mucous membranes, such as spasm of the larynx, bronchiolar constriction, and slowing or temporary cessation of the heart beat. In case of exposure to the fumes, a wet cloth should be applied over the mouth and nostrils. Burns from nitric acid should be treated immediately with sodium bicarbonate, and subsequently with oil applied on lint, and covered with cotton wool.

Preparations

Acidum Nitricum Dilutum, B.P.C.—(Acid. Nit. Dil.)—Dilute Nitric Acid. It contains from 9.5 to 10.5 per cent. w/w of HNO_3 . Dose.—0.3 to 1.2 millilitres (5 to 20 minims).

This dilute acid was included in the British Pharmacopæia, 1914

Acidum Nitro-Hydrochloricum Dilutum, B.P.C. (Acid. Nitro-hydrochlor. Dil.)—Dilute Nitro-hydrochloric Acid. It contains nitric and hydrochloric acids and various reaction products of the constituent acids, equivalent to about 12.5 per cent. w/w of nitric acid and about 13.5 per cent. w/w of hydrochloric acid. Dose.—0.3 to 1.2 millilitres (5 to 20 minims)

This dilute acid was included in the British Pharmacopæia, 1914

Mistura Gentianæ Acida, B.P.C.—(Mist. Gent. Acid.)—Acid Mixture of Gentian. Each fluid ounce contains 12 minims of dilute nitro-hydrochloric acid, with syrup of orange, compound infusion of gentian and chloroform water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

ACIDUM NUCLEICUM

(Acid. Nucleic.)

Nucleic Acid

Synonym—Nucleinic Acid.

The nucleic acids are complex organic acids of varying composition containing phosphorus in combination with varying amounts of protein, and occur as constituents of the nuclei of cellular organs both of animals and plants. These protein combinations of nucleic acids are known as nucleo-proteins and from them, by digestion with pepsin and hydrochloric acid, the greater part of the protein is removed, the undecomposed residue being known as nuclein, a term erroneously used as a synonym for nucleic acid. On hydrolysis of nuclein by pancreatin, or better by means of dilute alkalis, nucleic acids are obtained.

Nucleic acid prepared from yeast is most commonly employed. It occurs as a greyish-white or yellowish-white amorphous powder. It is acid to litmus, liberates carbon dioxide from carbonates and forms

salts with metals. Nucleic acid is gradually decomposed by boiling with dilute acids, or by prolonged heating with water, but is resistant to alkalis, especially in the presence of alkali acetates. On hydrolysis it yields, firstly, a mixture of compounds known as nucleotides, which are combinations of pyrimidine or purine groupings with a sugar and phosphoric acid; secondly, phosphoric acid is split off and nucleosides, compounds formed of pyrimidine or purine groupings with a sugar, are obtained, and finally, these are split up into the constituent pyrimidine or purine and a sugar. Nucleic acid contains about 13 per cent. of nitrogen and about 7 per cent. of phosphorus.

Insoluble in alcohol and ether, practically insoluble in water and dilute acids; soluble in dilute alkalis and in potassium acetate solution.

Action and Uses.—Nucleic acid is credited with some power to neutralise toxins present in the blood. In cases of tuberculosis it produces a reaction similar to that of tuberculin. Given by injection, it increases the number of white blood corpuscles. This effect is preceded by a hypoleucocytosis lasting some three or four hours; the leucocytes then leave their normal situations and come out in rapidly increasing numbers into the free circulation. It has been suggested, but on no definite evidence, that it may act as an indirect bactericide in tuberculosis, endocarditis, septicæmia and other bacterial infections. Nucleic acid is also given to heal chronic and varicose ulcers. Nucleic acid is **administered** internally in pills, cachets or tablets. It is best taken with or immediately following a meal.

Dose.—0·06 to 0·3 gramme (1 to 5 grains).

ACIDUM THYMINICUM.—Thymic acid, or nucleotin-phosphoric acid, occurs as a yellowish-brown amorphous powder. It is soluble in water and the solution is slightly acid. Thymic acid is a uric acid solvent said to be capable of holding in solution practically its own weight of uric acid at 20° and one and a half times its weight at blood temperature; on this evidence, it has been prescribed in the treatment of gout. **Dose.**—0·25 to 0·4 gramme (4 to 6 grains).

SODII NUCLEAS.—A 5 per cent. solution of sodium nucleate, prepared from nucleic acid with sufficient sodium hydroxide to produce a solution neutral in reaction to litmus, is used orally and by hypodermic injection; for hypodermic injection, 0·5 per cent. of phenol or chlorbutol is added. The solution is sometimes used in combination with sodium cacodylate and strychnine. An intramuscular injection is employed in the treatment of lobar pneumonia. Solutions for injection may be sterilised by tyndallisation at 70° for one hour on three successive days, by filtration, or when required in an emergency, by boiling the solution at 100° for thirty minutes. **Dose.**—4 to 8 millilitres (1 to 2 fluid drachms) of solution, by the mouth; 1 to 2 millilitres ($\frac{1}{4}$ to $\frac{1}{2}$ fluid drachm), by injection.

ACIDUM OLEICUM

(Acid. Oleic.)

Oleic Acid

Oleic acid may be obtained by the hydrolysis of fats or fixed oils, or by treating commercial oleins with superheated steam. The liquid

consists chiefly of $C_{17}H_{33}\cdot COOH$, but also contains some stearic and palmitic acids and usually traces of iron, probably derived from the vessels in which it is stored. It occurs as a colourless or yellowish, oily liquid having a slightly acid reaction and possessing a characteristic tallow-like odour and taste; on exposure to air the liquid darkens and the odour and taste become more pronounced. The solid or semi-solid mass obtained after cooling to about 4° remelts at about 14° . On the addition of 1 part of dilute sulphuric acid to a mixture of 1 part of oleic acid and 3 parts of a saturated aqueous solution of sodium nitrite, the oleic acid is converted after standing for a few hours into the solid stereoisomeride, elaidic acid.

Insoluble in water; readily soluble in alcohol (90 per cent.), ether chloroform, benzene and light petroleum.

Standard, B.P.—Oleic acid has a specific gravity of about 0.898. Acid value, 195 to 200. Iodine value, 85 to 90. Ash, not more than 0.1 per cent. w/w. It complies also with limit tests for stearic acid, mineral acids, neutral fats and mineral oils.

Action and Uses.—Oleic acid has been used internally in the treatment of gall-stones. Externally, it is used to assist the absorption of medicaments combined with it, such as alkaloids and mercury. It should not be used in the preparation of eye ointments.

Dose.—0.3 to 1 millilitre (5 to 15 minims).

ACIDUM OXALICUM

(Acid. Oxal.)

Oxalic Acid

Oxalic acid, $(COOH)_2, 2H_2O$, may be prepared by heating sawdust with potassium or sodium hydroxide, or by heating sodium formate, with subsequent liberation of the acid and purification by recrystallisation. It occurs in large, colourless, transparent, monoclinic crystals, which effloresce in the air. By taking special precautions it can be made to melt between 98° and 100° . The anhydrous acid volatilises, with partial decomposition, at a temperature of about 150° . The commercial product may contain as impurities the sulphates of sodium, potassium, calcium and lead, and extraneous organic matter. When to a solution of oxalic acid solution of calcium chloride and acetic acid are added, a minutely crystalline precipitate is produced which, on filtering and washing, decolourises potassium permanganate solution when mixed with dilute sulphuric acid and heated to 60° .

Soluble in water (1 in 12); less soluble in alcohol; sparingly soluble in ether; insoluble in chloroform, benzene and light petroleum.

Action and Uses.—Oxalic acid is poisonous to all forms of animal and plant life. In mammals it causes death by paralysis of the central

nervous system. The acid and the oxalates are rapidly absorbed from the gastro-intestinal tract and precipitate ionisable calcium from the blood and tissues; this property is utilised in the laboratory for preventing the clotting of samples of blood. The action of the oxalates can probably be attributed to the withdrawal of ionisable calcium from the tissues. Oxalic acid is used principally for technical purposes, and the purified acid as a laboratory reagent.

The antidote in cases of **poisoning** by oxalic acid is calcium hydroxide or calcium carbonate mixed with water. Soluble alkalis and carbonates, magnesia and magnesium carbonate should not be given, neither should the stomach tube be used, nor emetics administered unless the case is treated immediately after ingestion of the poison; it is preferable to convert the acid into the insoluble calcium salt and to induce evacuation by means of castor oil or an enema.

ACIDUM PHOSPHORICUM

(Acid. Phosph.)

Phosphoric Acid

Synonyms.—Acidum Phosphoricum Concentratum;
Concentrated Phosphoric Acid.

Phosphoric acid is orthophosphoric acid and may be obtained by the oxidation of phosphorus in contact with water. It is a stronger solution than the corresponding preparation of the British Pharmacopœia, 1914, which contained only 66.3 per cent w/w of H_3PO_4 , and had a specific gravity of 1.5. Phosphoric acid occurs as a clear, colourless and odourless liquid of syrupy consistence and has a strongly acid reaction even when freely diluted. When heated, it loses water and is converted finally into metaphosphoric acid, HPO_3 , which on cooling forms a transparent glassy mass known as glacial phosphoric acid; the commercial article contains usually a little sodium or ammonium metaphosphate added to facilitate its preparation in clear sticks or slabs.

Miscible in all proportions with water.

Standard, B.P.—Phosphoric acid contains not less than 88 and not more than 90 per cent. w/w of H_3PO_4 . Specific gravity, about 1.75. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. It complies also with limit tests for calcium and aluminium, phosphorous and hypophosphorous acids, chloride, sulphate and iron.

Action and Uses.—Phosphoric acid has none of the therapeutic properties of free phosphorus. It is **administered** internally in the diluted form, when it may be prescribed in larger doses than the other dilute mineral acids without interfering with the digestive processes. It is used as a gastric stimulant and to quench thirst. For

increasing the acidity of the urine it is much inferior to sodium acid phosphate.

Preparations

Acidum Phosphoricum Dilutum, B.P.—(Acid. Phosph. Dil.)—Dilute Phosphoric Acid. It contains 10 per cent. w/w of H_3PO_4 (limits, 9·5 to 10·5). Specific gravity, 1·054 to 1·060. It complies also with the tests for purity under **Acidum Phosphoricum** when eight times the quantity is taken for each test. Dose.—0·3 to 4 millilitres (5 to 60 minims).

Mistura Acidi Phosphorici, B.P.C.—(Mist. Acid. Phosph.)—Phosphoric Acid Mixture. Each fluid ounce contains 15 minims of dilute phosphoric acid with emulsion of chloroform, syrup of orange and compound infusion of gentian. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

ACIDUM SALICYLICUM

(Acid. Salicyl.)

Salicylic Acid

Salicylic acid is *o*-hydroxybenzoic acid, $C_6H_4(OH)\cdot COOH$, and may be obtained from the sodium salt prepared by the action of carbon dioxide on sodium phenate. In addition to this synthetically prepared variety there is also obtainable in commerce a "natural" acid prepared by the hydrolysis of naturally occurring salicylates such as oil of sweet birch. The natural acid is free from impurities which formerly were present in the synthetic product and is still sometimes preferred for medicinal use. The purest variety of the synthetic product is sometimes described as "physiologically pure." Salicylic acid occurs as colourless crystals or as a light feathery powder; it is almost odourless and has a sweetish, acrid taste. A deep violet colour is given on the addition of ferric chloride solution to an aqueous or an alcoholic solution. Salicylic acid dissolves in solutions of ammonium citrate, ammonium acetate, sodium phosphate, potassium citrate, sodium citrate and borax.

Soluble in water (about 1 in 500), boiling water (1 in 9), alcohol (90 per cent.) (1 in 3·5), ether (1 in 2), glycerin (1 in 200) and chloroform.

Standard, B.P.—Salicylic acid contains not less than 99·5 per cent. of $C_7H_6O_3$. Melting-point, 158° to 159° . Ash, not more than 0·05 per cent. Arsenic limit, 2 parts per million. Lead limit, 5 parts per million. It complies also with a limit test for iron and colouring matter.

Action and Uses.—Salicylic acid is a powerful antiseptic; it exerts a strong inhibitory influence upon the growth of micro-organisms, and retards the action of unorganised ferments as well as the ferments responsible for alcoholic and acetic fermentation. Applied to wounds, it is less irritating than phenol, but strong solutions exert a destructive action upon the horny layer of the epidermis, which is softened and

may easily be removed. Swallowed in powder or tablets, salicylic acid may cause irritation and corrosion of the mucous membrane of the mouth, throat and stomach. For internal use it has been replaced, almost entirely, by sodium salicylate and acetylsalicylic acid, which resemble it in therapeutic action.

Salicylic acid is used **externally** as an antiseptic and antipruritic in the treatment of wounds and parasitic skin diseases; it is also employed as a mouth-wash and as a local application to diminish sweating, especially when offensive. In concentrated solutions it is employed to remove such epidermal thickenings as corns and warts, and to destroy lupus. A solution of 1 in 1000 is sufficiently strong to preserve alkaloidal and similar solutions. Its use as a preservative of food and beverages is prohibited by the Public Health (Preservatives, etc., in Food) Regulations, 1925. Salicylic acid is **incompatible** with iron salts and spirit of nitrous ether.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

ACIDUM SALICYLSULPHONICUM.—Salicylsulphonic acid, $C_6H_5(SO_3H)(OH)COOH$, occurs in small, colourless, needle-shaped crystals. It gives a deep violet colouration with ferric chloride solution. Salicylsulphonic acid is used as a reagent to detect albumin in urine; a few crystals added to the clear urine produce a turbidity, if albumin is present, which is not affected by heat; the precipitate due to albumoses or peptones is dissolved on heating, but reappears on cooling.

Preparations

Amylum Salicylatum, B.P.C.—(Amylum Salicylat.)—Salicylated Starch. Salicylic acid, 1 in 10, with starch.

Collodium Salicylicum, B.P.C.—(Collod. Salicyl.)—Salicylic Collodion. Salicylic acid, about 1 in 8, in acetone and acetone collodion.

Collodium Salicylicum Compositum, B.P.C.—(Collod. Salicyl. Co.)—Compound Salicylic Collodion. *Syn.*—Collodium Callosum. Salicylic acid, about 1 in 8, and extract of cannabis, in acetone and acetone collodion.

Emplastrum Salicylicum Compositum, B.P.C.—(Emp. Salicyl. Co.)—Compound Salicylic Plaster. Salicylic acid, 1 in 5, and extract of cannabis, 1 in 10, with rubber adhesive plaster.

Emplastrum Salicylicum Compositum Fortius, B.P.C.—(Emp. Salicyl. Co. Fort.)—Stronger Compound Salicylic Plaster. Salicylic acid, 1 in $2\frac{1}{2}$, and extract of cannabis, 1 in 5, with rubber adhesive plaster.

Emplastrum Salicylicum Elasticum, B.P.C.—(Emp. Salicyl. Plast.)—Rubber Salicylic Plaster. Salicylic acid, 1 in 10, with rubber adhesive plaster. Rubber salicylic plasters are also prepared containing other proportions (from 5 to 40 per cent.) of salicylic acid.

Parogenum Salicylatum, B.P.C.—(Parogen. Salicylat.)—Salicylated Parogen. *Syn.*—Salicylated Vasoliment. Salicylic acid, 10 per cent. w/v, in parogen.

Pulvis Acidi Salicylici Compositus, B.P.C.—(Pulv. Acid. Salicyl. Co.)—Compound Salicylic Acid Powder. *Syn.*—Pulvis pro Pedibus. Salicylic acid 3 per cent., with boric acid and purified talc.

Pulvis Zinci et Acidi Salicylici, B.P.C.—(Pulv. Zinc. et Acid. Salicyl.)—Zinc and Salicylic Acid Powder. Zinc oxide, 20 per cent., and salicylic acid, 5 per cent., with starch.

Unguentum Acidi Salicylici, B.P.—(Ung. Acid. Salicyl.)—Ointment of Salicylic Acid. *Syn.*—Salicylic Acid Ointment. Salicylic acid, 2 per cent., in white paraffin ointment.

ACIDUM STEARICUM

(Acid. Stear.)

Stearic Acid

Stearic acid, sometimes incorrectly called "stearine," is a mixture of solid fatty acids, chiefly stearic and palmitic, obtained by the hydrolysis of various fats and subsequent removal of the liquid acids by cooling and filtration. It occurs in almost odourless and tasteless, white, hard masses, greasy to the touch and showing signs of crystallisation. Stearic acid may be powdered by sprinkling it with alcohol during trituration. Pure stearic acid, $C_{17}H_{35}COOH = 284.3$, is obtained by crystallising the commercial substance from hot alcohol, precipitating the alcoholic solution with magnesium acetate and decomposing the magnesium stearate by boiling with water and hydrochloric acid; it occurs in white, shining, flaky crystals, or as a hard, somewhat glossy solid, melting at 69.3° .

Insoluble in water; soluble in alcohol (1 in 50); readily soluble in ether and chloroform.

Standard.—Stearic acid does not melt below 54° . Acid value, 200 to 210. The solution obtained by boiling 1 gramme of the acid with 0.5 gramme of sodium carbonate dissolved in 30 millilitres of water, is not more than opalescent (limit of neutral fat or paraffin). Ash, not more than 0.1 per cent.

Uses.—Stearic acid is sometimes used as a substitute for wax in ointments and in the form of a powder as a lubricant in making compressed tablets. When partly neutralised it forms a creamy base with 5 to 15 times its weight of aqueous liquid and, in this form, is sometimes used as the basis of "vanishing" creams. The proportion of alkali used largely determines the appearance and plasticity of the cream. In this form it is used as a protective for the skin and with the addition of quinine it protects against sunburn in light treatment. When fully saponified and dissolved by heat in glycerin or alcohol, it will solidify with at least ten times its weight of liquid when cold. This property is utilised in making glycerin suppositories and "solid" tincture of iodine.

Preparations

Pasta Acidi Stearici, B.P.C.—(Past. Acid. Stear.)—Stearic Acid Paste. *Syn.*—Unscented Vanishing Cream. A non-greasy cream containing partially saponified stearic acid.

Pasta Hamamelidis, B.P.C.—(Past. Hamam.)—Hamamelis Paste. *Syn.*—Witch Hazel Cream. A non-greasy stearate cream containing about 50 per cent. w/w of solution of hamamelis.

ACIDUM SUCCINICUM

(Acid. Succin.)

Succinic Acid

Succinic acid, $(\text{CH}_2\cdot\text{COOH})_2$, may be prepared by the destructive distillation of amber, or by the fermentation of tartaric acid or malic acid; it is also obtained as a by-product of the fermentation of sugar. It occurs in colourless crystals having an acid taste. A neutralised solution of the acid yields a cinnamon-brown precipitate with ferric chloride solution which, when washed, decomposed by boiling with solution of ammonia and filtered, gives a solution from which white barium succinate is precipitated by the addition of solution of barium chloride and an equal volume of alcohol.

Soluble in water (1 in 20), and in less than its weight of boiling water; soluble in alcohol (1 in 9); slightly soluble in ether; insoluble in chloroform.

Standard.—Succinic acid, determined by the method of the British Pharmacopœia for Acidum Tartaricum, contains not less than 99.5 per cent. of $\text{C}_4\text{H}_6\text{O}_4$; each millilitre of N/1 sodium hydroxide is equivalent to 0.05902 gramme of $\text{C}_4\text{H}_6\text{O}_4$. Melting-point, not lower than 185° . Ash, not more than 0.1 per cent.

Action and Uses.—Succinic acid is rarely used in medicine. When administered orally it is neutralised in the duodenum and the sodium succinate so formed exerts a saline cathartic action similar to that of the salts of tartaric acid. It is absorbed very slowly and that portion absorbed is completely oxidised in the tissues.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

AMMONII SUCCINAS.—Ammonium succinate, $\text{C}_4\text{H}_4\text{O}_4(\text{NH}_4)_2$, may be obtained by the interaction of ammonia and succinic acid. It occurs in colourless crystals, soluble in water and alcohol. Its action resembles that of other salines—mildly diuretic, expectorant and diaphoretic. Dose.—0.12 to 0.3 gramme (2 to 5 grains).

ASPARAGINUM.—Asparagin, $\text{HOOC}(\text{NH}_2)\text{HC}(\text{CH}_3)\cdot\text{CONH}_2\cdot\text{H}_2\text{O}$, is the amide of aminosuccinic acid, and is found in the cell sap of plants. It forms colourless crystals, which are sweet in the case of *d*-asparagin, while *l*-asparagin has a disagreeable and cooling taste. It is soluble in water (1 in 50) and insoluble in alcohol. Asparagin has diuretic properties and has been given in cardiac dropsy, nephritis, and gout, it is, however, of doubtful physiological activity. Its solutions dissolve freshly precipitated mercuric oxide, and preparations of mercury aminosuccinate have been used for hypodermic injection in syphilis. Dose.—0.3 to 0.6 gramme (5 to 10 grains).

ACIDUM SULPHANILICUM

(Acid. Sulphanil.)

Sulphanilic Acid

Sulphanilic acid, $\text{C}_6\text{H}_4(\text{NH}_2)\text{SO}_3\text{H}\cdot 2\text{H}_2\text{O}$, is *p*-aminobenzenesulph-

onic acid, and may be prepared by heating together aniline and sulphuric acid. It occurs in colourless, needle-shaped crystals, which effloresce on exposure to air. It shows no melting-point, but is decomposed on heating at 280° to 300° . A cold solution in dilute hydrochloric acid, to which a cold solution of sodium nitrite has been added, produces a red precipitate when added to a solution of betanaphthol in sodium hydroxide solution.

Soluble with difficulty in cold water (about 1 in 160), but more readily in hot water; insoluble in alcohol, ether and benzene.

Standard.—Sulphanilic acid yields not more than 0.1 per cent. of ash. 1 gramme in 25 millilitres of boiling water, boiled, cooled and filtered, complies with the limit test for chlorides. 1 gramme in 25 millilitres of boiling water, cooled and filtered, complies with the limit test for sulphates.

Action and Uses.—Sulphanilic acid was formerly recommended for use in the treatment of iodism on the supposition that this condition was due to the liberation of iodine by nitrites in the body, but it has been shown that the acid does not react with nitrites in the animal body and its use for this purpose has been abandoned. It has also been given orally in the treatment of coryza, catarrh and as an analgesic. The acid is a constituent of Ehrlich's diazo-test for typhoid fever, now superseded by the Widal reaction.

Dose.—0.6 to 1.2 grammes (10 to 20 grains).

ZINCI SULPHANILAS.—Zinc sulphanilate, $(C_6H_5O_3NS)_2Zn \cdot 4H_2O$, may be prepared from sulphanilic acid and zinc oxide, and occurs in white, prismatic crystals, which effloresce slightly on exposure to the air. It is soluble in water (1 in 6), slightly soluble in alcohol, but insoluble in ether, chloroform and benzene. Sulphanilic acid is precipitated from its aqueous solution by sulphuric acid. The salt loses its water of crystallisation when dried at 100° . It is used as an astringent and antiseptic injection in leucorrhœa and gonorrhœa. In acute gonorrhœa it is used in dilute solutions (1 or 2 grains to 1 fluid ounce of water).

ACIDUM SULPHURICUM

(Acid. Sulph.)

Sulphuric Acid

Sulphuric acid may be obtained by dissolving the product of the oxidation of sulphur dioxide in water. It occurs as a colourless, corrosive liquid of oily consistence which evolves heat when added to water. Impure commercial sulphuric acid, known as concentrated oil of vitriol, "C.O.V.," contains about 98 per cent. w/w of H_2SO_4 ; brown oil of vitriol, "B.O.V.," contains 85 to 90 per cent. w/w of H_2SO_4 . Battery or accumulator acid is pure sulphuric acid diluted with distilled water to a specific gravity ranging from 1.20 to 1.26. Nordhausen or fuming

sulphuric acid, known commercially as "oleum," is prepared by the addition of sulphur trioxide to sulphuric acid and can be obtained containing various proportions of SO_3 ; it was formerly obtained by the distillation of ferrous sulphate.

Standard, B.P.—Sulphuric acid contains not less than 95 per cent. w/w of H_2SO_4 . Specific gravity, about 1.84. Ash, not more than 0.01 per cent. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. It complies also with limit tests for oxidisable impurities, nitrate, chloride and iron.

Action and Uses.—Sulphuric acid is a powerful escharotic, charring organic substances by virtue of its affinity for water. Applied to the skin, it causes intense pain and rapid destruction of tissue; it is even more irritating to mucous membrane. The concentrated acid is seldom employed in therapeutics, but was formerly used, mixed with sufficient charcoal to form a paste, as a caustic. It is **administered** as Acidum Sulphuricum Dilutum, which has an action similar to that of other dilute mineral acids. It is employed in the treatment of diarrhoea, its action being both antiseptic and astringent.

As a preventive of cholera epidemics, a drink colloquially known as "sulphuric acid lemonade," containing 5 to 10 minims of dilute sulphuric acid in a pint of sweetened water, has been found very efficacious. Aromatic sulphuric acid in the proportion of 5 to 20 minims to an ounce of sweetened water may be used instead. Dilute sulphuric acid is given in the treatment of lead colic; "sulphuric acid lemonade" is drunk by lead workers as a prophylactic of plumbism. Dilute sulphuric acid taken internally is said to be of value in obstinate cases of furunculosis. In cases of **poisoning** by sulphuric acid, the antidotes are calcium or magnesium hydroxide and water, or soap and water. The stomach pump and emetics should not be used. Opium and brandy are useful, and the usual means should be adopted against shock. Burns from sulphuric acid should be washed with water and treated with sodium bicarbonate, followed by oil, or sprayed with tannic acid solution.

Preparations

Acidum Sulphuricum Aromaticum, B.P.C.—(Acid. Sulph. Aromat.)—Aromatic Sulphuric Acid. *Syn.*—Elixir of Vitriol. It contains about 13 per cent. w/w of free and combined sulphuric acid, with tincture of ginger, spirit of cinnamon and alcohol (90 per cent.). Dose:—0.3 to 1.2 millilitres (5 to 20 minims).

This aromatic acid was included in the British Pharmacopœia, 1914

Acidum Sulphuricum Dilutum, B.P.—(Acid. Sulph. Dil.)—Dilute Sulphuric Acid. It contains 10 per cent w/w of H_2SO_4 (limits, 9.5 to 10.5). Specific gravity, 1.064 to 1.073. It complies also with a limit test for nitrate and with the other tests for purity under Acidum Sulphuricum, when nine times the quantity is taken for each test. Dose:—0.3 to 4 millilitres (5 to 60 minims).

Mistura Acidi Sulphurici cum Opio, B.P.C.—(Mist. Acid. Sulph. c. Opio)—Sulphuric Acid Mixture with Opium. Each fluid ounce contains 20 minims of dilute sulphuric acid and $7\frac{1}{2}$ minims of tincture of opium with tincture of capsicum and camphor water. Dose:—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

ACIDUM SULPHUROSUM

(Acid. Sulphuros.)

Sulphurous Acid

Sulphurous acid may be prepared by dissolving in water the gas obtained from liquefied sulphur dioxide, or by burning sulphur in air and passing the resulting sulphur dioxide into water. It occurs as a colourless liquid with a characteristic, suffocating odour. Its specific gravity is about 1.025. It is never free from traces of sulphates, and owing to the ease with which it becomes oxidised, it should be **stored** in completely-filled, stoppered bottles in a cool, dark place. Liquid sulphur dioxide is obtainable in siphons; it is a colourless, mobile liquid, boiling at about -8° and having a specific gravity of about 1.5.

Standard.—Sulphurous acid contains not less than 4.5 per cent. and not more than 5.5 per cent. w/w of SO_2 , corresponding to from 5.76 per cent. to 7.05 per cent. w/w of H_2SO_3 . Residue on evaporation and gentle ignition, not more than 0.01 per cent. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million.

Assay.—Mix about 1 gramme, accurately weighed, with 25 millilitres of N/10 iodine, allow to stand for about five minutes, and titrate the excess of iodine with N/10 sodium thiosulphate; each millilitre of N/10 iodine is equivalent to 0.003203 gramme of SO_2 .

Action and Uses.—Sulphur dioxide is a powerful antiseptic and disinfectant; it destroys protoplasm by its reducing action, in virtue of which it absorbs oxygen in the presence of moisture and is converted into sulphuric acid. When present in sufficient concentration (5 per cent. or more), it suffocates by inhibiting respiration or by producing spasm of the larynx. Although 0.5 per cent. can usually be tolerated for a long time, as little as 0.1 per cent. has been reported to cause death and even 1 part in 20,000 may irritate the eyes and bronchial tract.

Sulphur dioxide is a popular disinfectant used to fumigate rooms; for efficient disinfection about 2 to 4 volumes per cent. should be present in a moist atmosphere for at least twelve hours. From 2 to 4 pounds of sulphur should be burned for each 1000 cubic feet of air space, or its equivalent of liquefied sulphur dioxide vapourised, and the room sealed up for twenty-four hours. Sulphur dioxide and sulphites may be used as preservatives in sausages and sausage meat, dried and undried fruit and fruit pulp, certain sweetened or unsweetened non-alcoholic wines, cordials and fruit juices, jam, candied peel, sugar, glucose, beer, cider, alcoholic wines and sweetened mineral waters. The proportions, calculated as parts of sulphur dioxide per million, must not exceed those specified in the Public Health (Preservatives, etc., in Food) Regulations, 1925.

Sulphurous acid, mixed with an equal volume of glycerin or water, is applied externally for ringworm and other parasitic diseases and, when more diluted, for chapped hands and unbroken chilblains. In

tonsillitis and septic sore throat, sulphurous acid, or *Lotio Acidi Sulphurosi*, is used as a paint or spray. For inhalation in asthma and whooping cough, 4 millilitres (1 fluid drachm) may be added to 600 millilitres (1 pint) of cold or tepid water. Sulphurous acid, diluted with 10 parts of water, is useful for removing grease, mucus, etc., from marine sponges after their use in surgical operations. Sulphurous acid is **incompatible** with all oxidising agents.

Preparation

Lotio Acidi Sulphurosi, B.P.C.—(*Lot. Acid. Sulphuros.*)—Lotion of Sulphurous Acid. Sulphurous acid and glycerin of tannic acid, of each 1 in 4, in distilled water

ACIDUM TANNICUM

(*Acid. Tann.*)

Tannic Acid

Synonym—Tannin.

Tannic acid may be obtained from galls by subjecting them to a special fermentation and extracting with water-saturated ether. It occurs as yellowish-white or light brown, glistening scales, light masses, or as an impalpable powder; it has a characteristic odour and a strongly astringent taste. Tannic acid is not a carboxylic acid, but a tannin which contains a glucose nucleus and is converted by hydrolysis with dilute sulphuric acid into gallic acid and dextrose. This decomposition indicates that its minimum complexity is represented by a pentadigalloyl-glucose, $C_{76}H_{52}O_{46}$, a view in good accordance with its slightly acid reaction, molecular weight and dextro-rotation. It acts as a dibasic acid.

Many commercial samples contain gallic acid, the presence of which reduces the solubility and may be detected by the production of a pink colour on the addition of a 5 per cent. potassium cyanide solution. These varieties of tannic acid are used in dyeing, in the manufacture of ink, etc., and are not suitable for medicinal use; they occur in coarse powder or lumps, darker in colour than the official substance. An aqueous solution of tannic acid produces precipitates with solutions of gelatin, albumin, tartar emetic and some alkaloids. Tannic acid in aqueous solution undergoes hydrolysis slowly, and the oxidation of the gallic acid formed results in a dark-coloured solution. Tannic acid may be identified by the bluish-black colour produced on adding ferric chloride solution to the aqueous solution; the colour disappears on the addition of sulphuric acid with formation of a yellowish-brown precipitate.

Soluble in water (1 in 1), and alcohol (90 per cent.) (1 in 1); very soluble in acetone; slowly soluble in glycerin (1 in 1); almost insoluble in ether, chloroform, benzene and light petroleum.

Standard, B.P.—Tannic acid loses on drying at 100° not less than 6 per cent. and not more than 12 per cent. of its weight. Ash, not more than 0·2 per cent. It complies also with a limit test for gums, dextrin, sugars and salts.

Action and Uses.—Tannic acid is strongly astringent, but somewhat irritating. Its properties depend upon the formation of insoluble compounds with albumin and other proteins. Its solutions produce in the mouth a feeling of dryness and roughness, owing to coagulation of the protein material surrounding the epithelium and some of the superficial cells. In the stomach it combines with any proteid substance with which it may come in contact, forming an insoluble compound, but as digestion proceeds and the stomach contents become more acid, the protein tannate is broken up so that some uncombined tannic acid probably passes into the intestines. By coagulating proteins and diminishing the secretions in the small intestine, tannic acid tends to produce constipation. A small proportion, only about 1 per cent., reappears in the excretions either as tannic or gallic acid. The greater part of the tannic acid is converted in the alimentary canal into gallic acid, which is either absorbed or undergoes oxidation. Large doses may produce vomiting.

Tannic acid is seldom given **internally**, but is occasionally used for diarrhœa. As intestinal astringents the combined tannic acids existing in catechu, kino and rhatany, and also several synthetic compounds of tannic acid are preferred because they are less readily absorbed. It is much more generally used for **external** application. If it can be brought into direct contact with a bleeding surface it exerts a hæmostatic action, but it cannot control any form of remote hæmorrhage. The powder may be applied, or a solution (5 per cent.) on lint, or Collodium Stypticum may be employed. As an astringent for relaxed sore throats, *Glycerinum Acidi Tannici* may be used as a paint, or the acid employed in the form of a lozenge, gargle, or spray. Glycerin of tannic acid, when diluted with 6 or 8 parts of water, is also used in stomatitis, ozœna, inflamed tonsils and pharyngeal irritation. The powder is used for insufflation, for applying to the gums as an astringent, and, in the form of an ointment, for hæmorrhoids. Solutions (1 or 2 per cent.) are employed as lotions and injections for douching the nostrils in epistaxis and for use in leucorrhœa. A 20 per cent. solution in alcohol has been found useful for application to spongy and receding gums. In ulcerative colitis the bowel may be irrigated daily with a solution of tannic acid, 0·2 to 0·5 per cent., after gently washing it free from blood, mucus and fæces with warm saline solution. Suppositories of tannic acid are used as an astringent application to hæmorrhoids, sometimes with the addition of liquid extract of belladonna to allay pain. A warm, freshly prepared 2 per cent. aqueous solution is extensively used for the treatment of burns; *Lotio Acidi Tannici* is also suitable for this purpose. It may be sprayed on to the burned area by means of an atomiser, or applied as a moist dressing.

The acid may be **administered** in the form of a mixture or as a pill,

massed with one-eighth part of its weight of glycerin of tragacanth, and in cachets. Suppositories, pessaries and bougies are prepared with oil of theobroma. It is **incompatible** with salts of iron, lead, antimony and silver, alkaloids, albumin and gelatin. Tannic acid is sometimes given as an antidote in cases of poisoning by certain alkaloids, with the object of rendering insoluble any alkaloid remaining in the stomach. It is also used as an antidote in cases of antimonial poisoning.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

Preparations

Collodium Stypticum, B.P.C.—(Collod. Stypt.)—Styptic Collodion. Tannic acid, about 1 in 6½, with benzoin, alcohol, and simple collodion.

Gargarisma Acidi Tannici, B.P.C.—(Garg. Acid. Tann.)—Tannic Acid Gargle. Glycerin of tannic acid, 1 in 8, with distilled water.

Glycerinum Acidi Tannici, B.P.—(Glycer. Acid. Tann.)—Glycerin of Tannic Acid. Tannic acid, 15 per cent. w/w, dissolved in glycerin. Dose.—0.6 to 2 millilitres (10 to 30 minims).

Lotio Acidi Tannici, B.P.C.—(Lot. Acid. Tann.)—Lotion of Tannic Acid. Tannic acid, 2 per cent., and mercuric chloride, 1 in 2000, in distilled water.

Solvellæ Acidi Tannici Compositæ, B.P.C.—(Solv. Acid. Tann. Co.)—Compound Tannic Acid Solution-Tablets. Each solution-tablet contains 8½ grains of tannic acid and ¼ grain of mercuric chloride. One tablet dissolved in 1 fluid ounce of water forms a solution containing 2 per cent. of tannic acid and about 1 in 1750 of mercuric chloride.

Suppositorium Acidi Tannici, B.P.—(Supp. Acid. Tann.)—Tannic Acid Suppository. Each suppository contains 0.2 gramme (3 grains) of tannic acid.

Syrupus Iodotannicus, B.P.C.—(Syr. Iodotann.)—Iodotannic Syrup. Iodine and tannic acid, of each, 1 per cent. w/w with syrup and syrup of lemon. Dose.—1 to 4 millilitres (¼ to 1 fluid drachm).

Syrupus Iodotannicus cum Phosphate, B.P.C.—(Syr. Iodotann. c. Phosph.)—Iodotannic Syrup with Phosphate. Each fluid drachm contains about 2½ grains of calcium phosphate in iodotannic syrup. Dose.—1 to 4 millilitres (¼ to 1 fluid drachm), well diluted.

Trochiscus Acidi Tannici, B.P.—(Troch. Acid. Tann.)—Lozenge of Tannic Acid. *Syn.*—Tannic Acid Lozenge. Each lozenge contains approximately 0.03 gramme (½ grain) of tannic acid.

Unguentum Acidi Tannici, B.P.—(Ung. Acid. Tann.)—Ointment of Tannic Acid. *Syn.*—Tannic Acid Ointment. Tannic acid, 20 per cent., with glycerin, yellow beeswax and benzoinated lard.

ACIDUM TARTARICUM

(Acid. Tart.)

Tartaric Acid

Tartaric acid is *d*-dihydroxysuccinic acid, (CHOH·COOH)₂, and

may be prepared from argol, crude potassium acid tartrate. It occurs as odourless, colourless crystals, or as a white powder, with a strongly acid taste.

Soluble in water (1 in 0·8), alcohol (90 per cent.) (1 in 2·5); slightly soluble in ether.

Standard, B.P.—Tartaric acid contains not less than 99·5 per cent. of $C_4H_6O_6$, calculated on the substance dried at 100° . Loss on drying at 100° , not more than 1 per cent. Ash, not more than 0·1 per cent. Arsenic limit, 1 part per million. Lead limit, 20 parts per million. It complies also with limit tests for copper and iron, and sulphate.

Action and Uses.—Tartaric acid is wholly or partly neutralised in the intestine, and a very small portion is absorbed; the greater amount, however, passes through the alimentary canal as sodium tartrate, and acts as a saline aperient, tending to make the stools more watery. The portion absorbed is for the most part converted into sodium carbonate, which renders the urine less acid.

Tartaric acid is employed to make saline draughts and cooling drinks for febrile and diabetic patients; if not neutralised it must be taken well diluted, or severe gastro-enteritis may ensue. The following are the proportions necessary to form approximately neutral mixtures:—Tartaric acid, 10 parts, requires ammonium carbonate, about 7 parts; magnesium carbonate, about $6\frac{1}{2}$ parts; potassium bicarbonate, about $13\frac{1}{4}$ parts; sodium bicarbonate, about $11\frac{1}{4}$ parts. In cases of **poisoning** by tartaric acid, calcium hydroxide or magnesium hydroxide mixed with water should be given freely; the administration of alkali carbonates should be avoided.

Dose.—0·3 to 2 grammes (5 to 30 grains).

ACIDUM MALICUM.—Malic acid, $HOOC \cdot CHOH \cdot CH_2 \cdot COOH$, is contained in apples, pears, mountain-ash berries and many other fruits, also in rhubarb stalks. It occurs as colourless, odourless, prismatic crystals, readily fusible and deliquescent. It exists in two forms, dextro- and lævorotatory. An aqueous solution is not precipitated by calcium chloride, but on the addition of alcohol, a bulky, white precipitate of calcium malate is formed. Lead acetate solution produces a precipitate which is soluble in strong ammonia but, unlike lead tartrate and citrate, is not easily soluble in slight excess of ammonia. It is soluble in water, alcohol, and ether. The action of malic acid is similar to that of tartaric acid; it has been used in the preparation of effervescent salines.

AMYLIS TARTRAS.—Amyl tartrate, $(CHOH \cdot COOC_5H_{11})_2$, may be obtained by the esterification of isoamyl alcohol with tartaric acid and occurs as a colourless liquid with a specific gravity of about 1·05 and a boiling-point of about 400° . It is used as a plasticising solvent in the manufacture of lacquers and varnishes.

BUTYLIS TARTRAS.—Butyl tartrate, $(CHOH \cdot COOC_4H_9)_2$, may be obtained by the esterification of butyl alcohol with tartaric acid. It occurs as a colourless liquid with a specific gravity of about 1·064 to 1·091 and a boiling-range of 292° to 312° . It is miscible with oils and hydrocarbons and is used as a solvent in the manufacture of lacquers and varnishes.

ACIDUM TRICHLORACETICUM

(Acid. Trichloracet.)

Trichloroacetic Acid

Trichloroacetic acid, $\text{CCl}_3\cdot\text{COOH}$, may be prepared by the oxidation of chloral with nitric acid. It occurs as colourless, very deliquescent crystals or crystalline masses, with a characteristic, pungent odour. The acid melts at about 55° and boils at about 195° . When warmed with sodium hydroxide solution it is converted into chloroform with formation of sodium carbonate. It should be **stored** in well-closed containers.

Very **soluble** in water (about 9 in 1), giving a strongly acid solution; soluble in alcohol (90 per cent.) and ether.

Standard, B.P.—Trichloroacetic acid contains not less than 98 per cent. of $\text{C}_2\text{HO}_2\text{Cl}_3$. Ash, not more than 0.05 per cent. It complies also with limit tests for nitrate and chloride.

Action and Uses.—Trichloroacetic acid is applied **externally** as a caustic to venereal and other warts, and is less painful than nitric acid; the application of a crystal produces an eschar without subsequent inflammation. It has also been employed in strong solution, 1 part in 2 parts of glycerin, as a caustic in chronic pharyngitis. Liquefied trichloroacetic acid may be prepared by the addition of 10 per cent. of water to the crystalline acid. Weak solutions, containing 1 per cent. or less, have a powerful disinfectant action and such solutions may be applied to wounds and ulcers or used in erysipelas without causing irritation. As a delicate test for albumin in urine, a few drops of saturated solution are added to the filtered urine without mixing. In the presence of albumin a white cloudiness appears at the junction of the two liquids. It is also used as a quantitative test for proteins in certain body fluids, such as the cerebro-spinal fluid.

ACONITI FOLIUM

(Aconit. Fol.)

Aconite Leaf

Synonyms—Monkshood; Wolfsbane.

Aconite leaf consists of the dried leaves and flowering tops of *Aconitum Napellus* Linn. (Fam. Ranunculaceæ), a perennial herbaceous plant growing in the mountainous districts of Europe, Asia and North America, and cultivated in England. It is gathered when about one-third of the flowers are expanded. It is also used in the fresh condition.

The leaves are petiolate, dark green in colour, glabrous, roundish in

general outline, and divided down to the leaf stalk into three segments, the two lateral segments being again divided nearly to the base; each of the five divisions is pinnatifid, with linear, acute, tapering lobes, the lower being longer and somewhat spreading. The blue, zygomorphic flowers are arranged in a raceme. The calyx is petaloid, the posterior sepal being galeate and sub-hemispherical. The two posterior petals are modified to hammer-shaped nectaries enclosed by the posterior sepal, the remaining three being quite inconspicuous. The stamens are numerous with hairy filaments and the apocarpous gynoecium consists of three carpels. The herb has no odour; when cautiously chewed, a characteristic tingling and numbing sensation slowly develops. Calcium oxalate crystals are absent.

Aconite leaf **contains**, when dry, from 0.1 to 1.0 per cent. of total alkaloids. The poisonous alkaloid aconitine is undoubtedly one of the chief constituents, but the extent to which it occurs, and the nature of the other alkaloids that accompany it, are questions which have not yet been definitely answered. Probably both picraconitine (benzoyl-aconine) and aconine are present. It also contains aconitic acid and tannin.

Action and Uses.—The properties of aconite leaf are essentially those of the alkaloid aconitine. The drug has been used for the preparation of an extract, but its use is dangerous and the root is preferable.

ACONITINA

(Aconitin.)

Aconitine

Aconitine is an intensely poisonous alkaloid obtained from the roots of *Aconitum Napellus* Linn. It occurs in translucent, hexagonal prisms, or as a colourless, odourless, crystalline powder. The specific rotation in chloroform is about $+17.0^\circ$. An alcoholic solution of aconitine is slightly alkaline to litmus paper. One drop of a filtered aqueous solution (1 in 10,000) produces a characteristic, tingling sensation when placed on the tip of the tongue. 0.25 gramme, boiled on a water-bath for one hour with 2 millilitres of N/2 alcoholic solution of potassium hydroxide, leaves, on distilling off the alcohol, a residue which is soluble in water, and which, on acidification and extraction with ether, yields benzoic acid. On warming 0.05 gramme on a water-bath for five minutes with 4 drops of sulphuric acid, an odour of benzoic acid is perceptible, and on the addition of a crystal of resorcinol and further warming, a reddish-orange colour is produced. A solution in dilute acetic acid and water produces a blood-red or purple, crystalline precipitate on the addition of a few drops of potassium permanganate solution, and the mixture is not changed on the addition of bromine water (distinction from cocaine and hydrastine which become orange and

yellow respectively). It should be **stored** in well-closed containers protected from light.

Soluble in alcohol (1 in 30), ether (1 in 65), benzene (1 in 7) and chloroform (1 in 1); sparingly soluble in water.

Standard.—Aconitine, when heated rapidly, melts between 196° and 200° , with evolution of acetic acid. Ash, not more than 0.1 per cent. No colour is produced immediately on dissolving 0.05 gramme in 4 drops of sulphuric acid. 0.01 gramme dissolved in 5 drops of fuming nitric acid and evaporated to dryness on a water-bath leaves a yellow residue which does not become red when moistened with N/2 alcoholic solution of potassium hydroxide (limit of pseudoaconitine).

Action and Uses.—Aconitine is rarely given **internally** on account of its extremely powerful cardiac action. It has a very characteristic effect on sensory nerve endings. It is not absorbed through unbroken skin, but when applied with alcohol or fat, typical tingling, followed by numbness, is produced. When taken by the mouth the same excitation of the sensory nerve endings is induced, and this is especially marked in the more sensitive parts of the body, such as the tongue, throat and finger-tips. This action has led to its employment in trigeminal neuralgia. The medulla is first excited and then depressed; hence, after small doses, respiration is increased in depth and frequency, the pulse becomes slower, and the peripheral vessels tend to constrict, but the blood pressure does not rise on account of the decided cardiac slowing. Large doses quicken the heart and may produce marked cardiac irregularities. It produces a marked fall in temperature both in fever and in normal conditions. It is used **externally** in the form of ointment to relieve neuralgic pains, but should not be applied to mucous surfaces or to abraded skin. In cases of **poisoning** by aconitine, the treatment described under Aconitum should be applied.

Dose.—0.0001 gramme ($\frac{1}{10000}$ grain).

ACONITINÆ HYDROBROMIDUM.—Aconitinehydrobromide, $C_{34}H_{47}O_{11}N$, $HBr \cdot 2\frac{1}{2}H_2O$, crystallises from water in rhombic plates. It sinters at 163° to 164° ; after drying *in vacuo* at 110° it melts between 176° and 180° . It is soluble in water and alcohol. Dose.—0.0001 gramme ($\frac{1}{10000}$ grain).

ACONITINÆ HYDROCHLORIDUM.—Aconitinehydrochloride, $C_{34}H_{47}O_{11}N$, $HCl \cdot 3H_2O$, crystallises from water in rhombic plates. It melts at about 149° and, after drying *in vacuo* at about 174° . It is soluble in water and in alcohol. Dose.—0.0001 gramme ($\frac{1}{10000}$ grain).

ACONITINÆ NITRAS.—Aconitine nitrate, $C_{34}H_{47}O_{11}N \cdot HNO_3$, occurs in the form of colourless, prismatic crystals. It melts at about 200° . It is soluble in boiling water (1 in 10). Salts of aconitine, preferably the nitrate (1 in 500,000 in distilled water), are of considerable value in the treatment of neuralgia by ionisation. Solutions for injection may be sterilised by tyndallisation at 70° for one hour on three successive days, or by filtration. The containers must comply with tests for limit of alkalinity of glass. Dose.—0.0001 gramme ($\frac{1}{10000}$ grain).

Preparations

Collodium Anodynum, B.P.C.—(Collod. Anodyn.)—Anodyne Collodion. *Syn.*—Anodyne Colloid. Aconitine, about 0.1 per cent. w/v, and veratrine, about 0.7 per cent. w/v, in acetone and acetone collodion.

Unguentum Aconitinæ, B.P.C.—(Ung. Aconitin.)—Aconitine Ointment. Aconitine, 2 per cent., in oleic acid and lard.

This ointment was included in the British Pharmacopœia, 1914.

ACONITUM

(Aconit.)

Aconite

Synonyms—Aconiti tuber I.A.; Aconiti Radix; Aconite Root.

Aconite is the dried root of *Aconitum Napellus* Linn. (Fam. Ranunculaceæ). The roots are dried either entire or longitudinally sliced.

The root is dark brown and obconical, and bears numerous rootlets or the scars left by them. It varies from about 4 to 10 centimetres in length and from 1 to 3 centimetres in width at the crown, to which is attached the base of the aerial stem or the remains of a bud. The fracture is short, and the smoothed, transverse surface exhibits a thick bark separated from the inner portion by a darker stellate cambium with 5 to 8 projecting angles. Aconite has a faint odour; the taste is at first slight, but is followed by a persistent sensation of tingling and numbness.

The diagnostic **microscopical** characters are the brown-walled, tabular cells of the metaderm; the occasional sclerenchymatous cells, of various shapes and with lignified walls, from the parenchymatous tissue of the cortex and secondary phloem; the abundant parenchyma containing small starch grains, simple or 2 to 5-compound, individual grains measuring up to 30 microns in diameter; fragments of vessels; the absence of fibres and calcium oxalate crystals.

Aconite **contains** the three alkaloids, aconitine (acetylbenzoyl-aconine), picroaconitine (benzoylaconine or benzaconine) and aconine, but it is to the first-named only that the toxic action of the root is due. The total amount of alkaloid present varies from 0·2 to 1·5 per cent. The ether-soluble alkaloids (chiefly aconitine) vary usually from 0·3 to 0·6 per cent. Other constituents are starch and aconitic acid.

Varieties.—English root consists chiefly of daughter roots each of which is crowned by the remains of a bud. Much of the aconite at present in commerce is imported from Germany and consists chiefly of the dried parent root of the flowering plants. It may be recognised by the remains of the aerial stem which crown the root; it is also generally less starchy, darker internally and more shrivelled than English root.

Substitutes.—Japanese aconite is said to be obtained from *A. uncinatum* Linn. var. *japonicum* Regel; it is distinguished by its dark greyish colour, smaller size, smoother surface and circular cambium; it contains japaconitine (acetylbenzoyl-japaconine) which has an action similar to that of aconitine and may be identical with it. Indian (Nepaul) aconite (bikh or bish) consists of the root of *A. deinorrhizum* Stapf; the larger size and less tapering character sufficiently distinguish it from the official drug. It contains pseudoaconitine (acetylveratroylpseudoaconine), which

is about twice as active as aconitine. Atis root (*A. heterophyllum* Wall) and the roots of certain other species of *Aconitum* occur in commerce; they contain non-poisonous alkaloids and may be distinguished by the absence of a tingling taste.

Standard, B.P.—Aconite contains not more than 2 per cent. of other organic matter. The British Pharmacopœia states that there is no trustworthy chemical method of assay for aconite and that it is not considered to be a drug of sufficient medicinal value to justify a biological method of assay.

Aconite, in powder (*Pulvis Aconiti* : *Pulv. Aconit.*), contains the constituents and possesses the diagnostic microscopical characters of the unground drug. *Pulvis Aconiti* I.A. is adjusted, by dilution with rice starch if necessary, to contain 0.5 per cent. of total alkaloids.

Action and Uses.—The properties of aconite are virtually those of aconitine. Owing to the extremely poisonous nature of the drug, all preparations thereof should be used with great care. For **internal** use, the tincture, well diluted, is employed as a mild diaphoretic to reduce feverishness in common colds, and in the early stages of acute infections, such as tonsillitis, laryngitis, and bronchitis. Very small doses, frequently repeated, are preferred to full doses to diminish the frequency of the pulse. Preparations of aconite are not usually given when there is cardiac disease. **Externally**, the liniment, compound paint and chloroform of aconite are used as anodynes in neuralgia, sciatica and acute rheumatism, but such preparations must not be used on abraded surfaces on account of the danger of absorption. A strong tincture is prepared for external application, and is sometimes used with an equal quantity of strong or weak solution of iodine to paint the gums in dental periostitis. This tincture is an extremely powerful preparation. Aconite plasters are prepared in rubber combination, and pastilles are used in tonsillitis and laryngitis, but should not be administered too freely. In cases of **poisoning** by aconite, the stomach should be emptied by means of the stomach pump, or apomorphine, $\frac{1}{10}$ grain, should be given hypodermically. An emetic of mustard, zinc sulphate, or ipecacuanha, followed by stimulants, and atropine and digitalis have been recommended. The patient should be kept lying down, and warmth applied.

Preparations

Chloroformum Aconiti, B.P.C.—(*Chlorof. Aconit.*)—Chloroform of Aconite. A 1 in 1 preparation of aconite, obtained by percolating the drug, previously moistened with dilute solution of ammonia, with a mixture of chloroform and alcohol.

Linimentum Aconiti, B.P.—(*Lin. Aconit.*)—Liniment of Aconite. An alcoholic extract of aconite, 1 in 2, prepared with alcohol (90 per cent.), or with industrial methylated spirit suitably diluted, and containing also 3 per cent. w/v of camphor.

Linimentum Aconiti Oleosum, B.P.C.—(*Lin. Aconit. Oleos.*)—Liniment of Aconite with Oil. *Syn.*—A B.C. Liniment. Equal parts of liniment of aconite, liniment of belladonna and liniment of chloroform. The non-oily liniment of the British Pharmaceutical Codex, 1923 is included under the name of *Pigmentum Aconiti Compositum*.

Pigmentum Aconiti Compositum, B.P.C.—(Pig. Aconit. Co.)—Compound Aconite Paint. Liniment of aconite and liniment of belladonna, of each 37·5 per cent. v/v, with chloroform and distilled water.

Pigmentum Iodi et Aconiti, B.P.C.—(Pig. Iod. et Aconit.)—Iodine and Aconite Paint. Weak solution of iodine and strong tincture of aconite, equal parts.

Tinctura Aconiti, B.P.C.—(Tinct. Aconit.)—Tincture of Aconite. About 1 in 6. Dose.—0·12 to 0·3 millilitre (2 to 5 minims).

This tincture, standardised to contain 0·04 per cent. w/v of ether-soluble alkaloids, was included in the British Pharmacopœia, 1914.

Tinctura Aconiti I.A. is prepared with alcohol (70 per cent.) and contains 0·05 per cent. of total alkaloids. Extractum Aconiti I.A. contains 1 per cent. of total alkaloids. Sirupus Aconiti I.A. is prepared from the tincture and contains 0·0025 per cent. of total alkaloids.

Tinctura Aconiti Fortis, B.P.C.—(Tinct. Aconit. Fort.)—Strong Tincture of Aconite. *Syn.*—Fleming's Tincture of Aconite. It is about five times the strength of Tinctura Aconiti and is not used for internal administration.

ACRIFLAVINA

(Acriflavin.)

Acriflavine

Acriflavine is a mixture of the hydrochlorides of 2:8-diamino-10-methylacridinium chloride and diaminoacridine, and may be prepared by the combination of methyl *p*-toluenesulphonate with 2:8-diacetyldiaminoacridine and hydrolysis of the product with hydrochloric acid. It occurs as an odourless, orange-red or brownish-red, crystalline powder, with an acid taste. The 0·1 per cent. aqueous solution is fluorescent and has a deep orange colour, changing to red on the addition of a few drops of solution of methyl orange. Acriflavine may be distinguished from fluorescein by the bulky yellow precipitate produced on the addition of a 10 per cent. solution of sodium salicylate. It may be determined volumetrically by the assay process for Euflavina; each millilitre of M/10 potassium ferricyanide is equivalent to 0·08883 gramme of $\text{C}_{14}\text{H}_{14}\text{N}_3\text{Cl}\cdot\text{HCl}$.

Soluble in water (1 in 3), and alcohol (90 per cent.); almost insoluble in ether, chloroform, liquid paraffin, and fixed and volatile oils.

Standard, B.P.—Acriflavine, after moistening with sulphuric acid and gently igniting, and again moistening and igniting, leaves not more than 1 per cent. of residue. It complies also with a limit test for proflavine and with tests for the stability of its solutions in water and in normal saline.

Action and Uses.—Acriflavine is a powerful antiseptic. It has been credited with trypanocidal powers, though it is not now used in the treatment of trypanosomiasis. Its bactericidal action is increased by the presence of serum and in this respect it differs from most other antiseptics; the presence of whole blood appears to diminish its activity.

Concentrations sufficient to inhibit the growth of organisms do not interfere with normal phagocytic action and are without harmful effect on the tissues locally, hence its suitability in the treatment of suppurating wounds, but it should be noted that, after prolonged treatment, wounds tend to become sluggish in healing. Solutions of 1 in 1000 in normal saline are recommended, but weaker solutions are sometimes used. *Emulsio Acriflavinæ* is a suitable application for general use. Pessaries are usually composed of one part of acriflavine in 500 parts of oil of theobroma or glycerin suppository basis.

Acriflavine can be employed as a urinary disinfectant and has been used in the treatment of gonorrhœa, being given by the mouth in doses of 0.1 gramme ($1\frac{1}{2}$ grains) three times daily, or intravenously in smaller doses. Solutions for **injection** may be prepared by aseptic methods and stored protected from light. Its action is more marked if the urine is kept alkaline. Recently it has been shown that its use internally is not without risk of grave toxic results. Cases have been reported in which death has followed its administration, the liver and kidneys being the organs particularly affected. The jaundice occurring in these cases may be delayed for weeks or months after the last dose. Acriflavine stains may be removed by the application of a dilute solution of sulphurous acid.

AURAMINA.—Auramine is tetramethyldiaminodiphenylketonimine hydrochloride, and occurs as a yellow powder soluble in water. The aqueous solution decomposes slowly in the cold but rapidly on heating. It is used as a non-irritant antiseptic in dilute aqueous solution (0.1 to 1 per cent.).

QUINANILUM.—Quinamil, or "48S," is a sulphonated-2-(*p*-dimethylaminoanil)-6-methylquinoline methochloride and is used in dilute aqueous solution as an antiseptic in the treatment of wounds and various infections, particularly of the genito-urinary system.

Preparations

Emulsio Acriflavinæ, B.P.C. (*Emuls. Acriflavin.*)—Emulsion of Acriflavine. Acriflavine, 1 in 1000, with liquid paraffin, white beeswax and distilled water.

Liquor Acriflavinæ, B.P.C. (*Liq. Acriflavin.*)—Solution of Acriflavine. Acriflavine, 0.1 per cent. w/v, in physiological solution of sodium chloride.

ADEPS

(*Adeps*)

Lard

Synonyms.—*Adeps Præparatus*; Prepared Lard.

Lard is the purified internal fat of the hog, *Sus scrofa* Linn. (Order Ungulata). It is prepared from the "flare," or omentum, by washing the fat, leafy masses and removing external membranes as far as possible; the product is then heated to a temperature not above 57° until the fat has melted, and strained. It is a soft, white, unctuous fat

with a faint, but not rancid, odour and yields when melted a clear liquid which does not deposit on standing.

Lard may be identified by the characteristic shape of the crystals deposited from a 25 per cent. w/v ethereal solution on standing for eighteen hours at 20°, when mounted in alcohol (95 per cent.) or in a fixed oil; the crystals form irregular groups of flat, rhomboidal plates, cut off obliquely at one end. Lard consists of olein, about 60 per cent., associated with variable amounts of stearin and palmitin, approximately 40 per cent.; it does not contain any vitamins.

Insoluble in water; very slightly soluble in alcohol (90 per cent.); soluble in ether (1 in 22), oil of turpentine (1 in 16), chloroform and light petroleum; it is also soluble in carbon disulphide yielding a slightly turbid solution.

Standard, B.P.—Lard, after preliminary treatment as described, melts between 34° and 41°. Refractive index at 60°, 1.452 to 1.455. Acid value, not more than 1.2. Saponification value, 192 to 198. Unsaponifiable matter, not more than 0.5 per cent. Iodine value, 52 to 66. It complies also with tests for the absence of beef fat, sesame oil, cotton-seed oil, alkalis and chloride.

Uses.—Lard is employed as a basis for the preparation of ointments which are intended to be absorbed. On account of its tendency to become rancid it is, however, less used than formerly. When used in the form of *Adeps Benzoïnatus*, the benzoic acid present in the benzoïn acts as an antiseptic and prevents the lard from becoming rancid. The acid, however, renders the lard slightly irritant and unsuitable for application to such sensitive parts as the conjunctiva. Benzoïnated lard should not be used in the preparation of ointments containing alkaloidal bases. In India, suet should be used for making preparations for which lard is directed to be used.

OLEUM ADIPIS.—Lard oil may be obtained by pressure from lard. It occurs as a colourless, or pale yellow, oily liquid, having a peculiar odour and bland taste. It is slightly soluble in boiling alcohol, and easily soluble in ether, chloroform, benzene and carbon disulphide.

Preparation

Adeps Benzoïnatus, B.P.—(*Adeps Benz.*)—Benzoïnated Lard. Lard containing the fat-soluble matter from 3 per cent. of benzoïn.

ADEPS LANÆ

(*Adeps Lan.*)

Wool Fat

Synonym—Anhydrous Lanolin.

Wool fat is the purified, anhydrous, fat-like substance obtained from the wool of the sheep, *Ovis aries* Linn. (Order Ungulata). The

natural grease is extracted from the wool by kneading with water, with which it readily forms an emulsion; on heating, it separates as a distinct layer at the surface of the liquid. Purification is effected by repeated treatment with water in a centrifugal machine or by other methods. It occurs as a pale yellow, tenacious, unctuous substance with a faint but characteristic odour, and melts at about 37°.

Wool fat is a wax and contains the alcohols cholesterol and iso-cholesterol, together with various esters, the acids in combination being lanoceric, lanopalmitic, carnaubic, myristic, oleic, and probably cerotic and palmitic acids. A distinctive test is that for cholesterol; 1 gramme of wool fat, dissolved in 3 or 4 millilitres of acetic anhydride, gives with 0.3 millilitre of sulphuric acid a pink colouration soon changing to green and blue. When a 2 per cent. solution in chloroform is gently poured over the surface of concentrated sulphuric acid a purple-red colouration is developed at the junction of the liquids. It is practically impossible to saponify wool fat with aqueous solution of potassium hydroxide, but saponification may be effected by alcoholic potash under pressure or by solution of sodium ethylate.

Insoluble in water; sparingly soluble in cold alcohol (90 per cent.), but more soluble in boiling alcohol (90 per cent.) (about 1 in 75), the solution depositing most of the wool fat in the form of flocks; freely soluble in ether, chloroform, carbon disulphide, acetone, benzene and light petroleum.

Standard, B.P.—Wool fat has a melting-point of 34° to 40°. It loses, when dried at 100° for one hour, not more than 0.5 per cent. Ash, not more than 0.15 per cent. Acid value, not more than 1. Saponification value, 94 to 106. Iodine value, 18 to 32. It complies also with a test for absence of free alkali and with a limit test for chloride.

Action and Uses.—Wool fat is closely allied to the natural secretions of the skin; it is not very readily absorbed, but when mixed with olive oil or soft paraffin it readily penetrates the skin and is useful for promoting the cutaneous absorption of drugs. Unlike lard, it does not readily become rancid. It takes up about 50 per cent. of water and is thus available for use in ointments in which the proportion of water is too great to permit of incorporation with any other fatty base. By the addition of a small quantity of wool fat to soft or liquid paraffin, the latter can be formed into stable emulsions with water, as in the preparation of parenols.

Hydrous wool fat is employed as an ointment basis, generally for substances in aqueous solution. It may be mixed with olive oil, soft paraffin, or lard, by which its stickiness is much diminished and its absorbability increased. Wool fat should be used in preference to hydrous wool fat in the preparation of ointments containing phenol, mercuric chloride, or other antiseptics, so as to minimise the caustic action resulting from absorption.

CHOLESTEROL.—Cholesterol, $C_{27}H_{46}O, H_2O$, is the crude sterol prepared from wool fat, bile, gall stones, or blood. It may be obtained from wool fat by saponification with potassium hydroxide and extraction with ether. It occurs as a white, inodorous, crystalline substance, soluble in ether and hot alcohol, but insoluble in water. It melts at about 145° . Cholesterol is present normally in the blood to the extent of about 0.18 per cent. In certain forms of nephritis, particularly the chronic parenchymatous variety, a rise in blood cholesterol to 0.3 per cent. may be observed. Cholesterol has been suggested as a local stimulating application in alopecia; lotions should contain 0.25 to 0.5 per cent. w/v in alcohol with 3 to 5 per cent. of glycerin. The addition of 0.5 to 1 per cent. of cholesterol to soft paraffin renders possible the incorporation of 10 to 20 per cent. of an aqueous solution in an ointment. Contrary to original ideas, irradiated solutions of highly purified cholesterol have no antirachitic potency.

Preparations

Adeps Lanæ Hydrosus, B.P.—(Adeps Lan. Hydros.)—Hydrous Wool Fat. *Syn*—Lanolin. Wool fat, with 30 per cent. of water.

Unguentum Adipis Lanæ, B.P.C.—(Ung. Adip. Lan.)—Wool Fat Ointment. *Syn*—Unguentum Lanolini Anhydrosi; Anhydrous Lanolin Ointment. Wool fat and yellow soft paraffin, equal parts.

Unguentum Adipis Lanæ Compositum, B.P.C.—(Ung. Adip. Lan. Co.)—Compound Wool Fat Ointment. *Syn*—Unguentum Lanæ Compositum; Emollient Ointment. Lard and wool fat, of each 40 per cent., and yellow paraffin ointment, 20 per cent.

This ointment was included in the British Pharmacopœia, 1914, under the name of Unguentum Lanæ Compositum

Unguentum Adipis Lanæ Hydrosi, B.P.C.—(Ung. Adip. Lan. Hydros.)—Hydrous Wool Fat Ointment. *Syn*—Unguentum Lanolini; Lanolin Ointment. Hydrous wool fat and yellow soft paraffin, equal parts.

ADHATODA

(Adhat.)

Adhatoda

Synonyms—Adhatodæ Folia; Malabar Nut Leaves; Vasaka.

Adhatoda consists of the leaves of *Adhatoda Vasica* Nees (Fam. Acanthaceæ), a shrub or small tree indigenous to and cultivated in India.

The leaves vary from 10 to 20 centimetres in length and are about 3.5 to 6 centimetres broad; they are entire, lanceolate, somewhat acuminate and shortly petiolate. When dry, they are dull greenish-brown, and possess a characteristic odour and bitter taste.

The diagnostic **microscopical** characters are stomata of the caryophyllaceous type, few on the upper surface and very numerous on the lower surface; the epidermis, bearing one- to three-celled, thin-walled, warty trichomes and small, sessile, quadricellular glands; the fairly large, elongated cystoliths occurring in the hypodermal and cortical parenchyma of the under surface, but never in the epidermis.

Adhatoda **contains** a bitter, crystalline alkaloid, vasicine ($C_{11}H_{12}ON_2$, melting-point, about 190° to 191°), which is said to exist in combination

with an acid that has been named adhatodic acid. A second alkaloid has been reported to be present, as well as an odorous, volatile principle, organic acids and mucilage.

Action and Uses.—Adhatoda acts as an irritant to the alimentary canal, large doses causing vomiting and diarrhœa. It is used as an expectorant in the form of liquid extract, juice, syrup and tincture. More rarely, in asthmatic conditions, the leaves are dried and smoked in the form of cigarettes. It is used in India and the Eastern Colonies, and is said to be non-poisonous to mammals, but to kill fish, insects and lower organisms.

ADRENALINA

(Adrenal.)

Adrenaline

Synonyms—Adrenalinum; Adrenalin; Epinephrine.

Adrenaline, *l* - α - 3 : 4 - dihydroxyphenyl - β - methylaminoethanol, $\text{C}_6\text{H}_3(\text{OH})_2\text{CHOH}\cdot\text{CH}_2\cdot\text{NH}\cdot\text{CH}_3$, is an active principle of the suprarenal gland, and may be prepared from an acid extract of the glands of certain mammals, or synthetically. The synthetic base may be prepared from catechol by interaction with chloroacetyl chloride and treatment of the resulting chloroacetylcatechol with methylamine, followed by reduction. The product so obtained is the racemic form and resolution and removal of the less active dextro-base can be effected by crystallisation of the *d*-tartrates, the *l*-adrenaline salt being the more sparingly soluble. It should be kept dry and **stored** in dark-coloured glass containers.

Adrenaline occurs as a white or pale buff-coloured, sphæro-crystalline, odourless powder; it has a slightly bitter taste and produces a temporary numbing effect on the tongue. It dissolves readily in dilute mineral acids and in aqueous solutions of sodium hydroxide or of potassium hydroxide, but not in solutions of ammonia or of the alkali carbonates. Neutral or alkaline solutions are unstable and rapidly become red on exposure to the air. When a few drops of 0.25 per cent. ferric chloride solution are added to a neutral or faintly acid solution of adrenaline, an emerald-green colour is produced which changes to red on standing or on the addition of sodium bicarbonate solution. When 1 millilitre of a solution containing adrenaline is mixed with 1 millilitre of a 0.2 per cent. solution of potassium persulphate and the mixture gently warmed, a red colour slowly appears. A similar colour is formed by treatment with other oxidising agents such as potassium ferricyanide, potassium permanganate, potassium dichromate, hydrogen peroxide, etc. On mixing 1 millilitre of a solution of adrenaline with 2 millilitres of a 10 per cent. ammonium molybdate solution a yellow colour

develops instantly; this test is also given by certain other reducing substances. Adrenaline is not precipitated by potassio-mercuric iodide solution or by picric, tannic, phosphomolybdic, or phosphotungstic acids.

Sparingly **soluble** in water; insoluble in alcohol (90 per cent.), ether, chloroform, liquid paraffin and other organic solvents; slightly soluble in oleic acid with colouration due to the presence of iron in the acid.

Standard, B.P.—Adrenaline has a melting-point of 205° to 212° with decomposition (the rate of rise of temperature being 10° per minute). Ash, not more than 0.01 per cent. A solution in N/1 hydrochloric acid complies with limits for specific rotation.

Action and Uses.—The action of adrenaline is comparable to the effects produced by stimulating the sympathetic nervous system. When injected into the circulation it produces a rapid rise in blood pressure which is brought about largely by the constriction of all vessels innervated by the sympathetic. At first there is acceleration of the heart-beat, but this is followed by slowing and strengthening of the beat owing to the stimulation of the cerebral vagus centre. Intravenous injection of adrenaline has been recommended as a cardiac stimulant in sudden failure, and to relieve surgical, vesical and intestinal bleeding; it is contra-indicated in hæmorrhage occurring during light chloroform anæsthesia. It is usually administered as *Liquor Adrenalinæ Hydrochloridi*. For intravenous injection, the solution is diluted with 100 to 200 times its volume of physiological sodium chloride solution. It must, however, be remembered that adrenaline should not be injected intravenously except in emergency. Adrenaline is rapidly destroyed in the circulation and its effects are, therefore, transient. Injection directly into the heart has been employed in cases of apparent death. Subcutaneous injection gives rise to local constriction of the vessels, and adrenaline is therefore used, in the dilution of 1 in 30,000 to 1 in 100,000, with local anæsthetics to reduce the hæmorrhage in surgical operations, to prevent absorption and to localise the effect of the anæsthetic. Strong solutions of adrenaline should not be used for hypodermic injection, since they cause ischæmia of the part, which may be followed by sloughing.

Adrenaline is useful in the treatment of anaphylactic reactions or the allergic state, such as urticaria, angioneurotic œdema, hay fever and serum rash, also for counteracting the toxic effects of overdosage with arsphenamine. Subcutaneous injections almost immediately relieve the symptoms in cases of acute spasmodic asthma; here it acts by exciting the broncho-dilator nerve (sympathetic), in contrast to atropine, which depresses the broncho-constrictors (vagus). Injected into the uterus, it arrests post-partum hæmorrhage, promoting contraction of the uterine muscle and constricting the vessels. Although general systemic effects are more satisfactorily obtained from hypodermic than from oral administration, doses of 0.3 to 0.6 millilitre (5 to 10 minims) of *Liquor Adrenalinæ Hydrochloridi* are given by

the mouth to prevent heart failure in diphtheria. In whooping cough, doses of 0.12 to 0.3 millilitre (2 to 5 minims) by the mouth are said to give good results. It is also used to counteract an overdose of insulin.

Externally, it is employed as a vasoconstrictor and hæmostatic. When applied to mucous membranes it produces ischæmia by constricting the peripheral vessels; it therefore relieves turgescence and is of use in hay fever and other oral, laryngeal, or nasal inflammations. For use as a nasal spray in coryza, hay fever, asthma, epistaxis, etc., a solution of 1 in 5000 to 10,000 is suitable, or Nebula Adrenalinæ Aromatica or Nebula Adrenalinæ et Cocainæ may be used. Adrenaline is applied to the eye in various forms of conjunctivitis, trachoma, etc., for reducing intra-ocular tension in glaucoma and also to arrest progressive myopia. It controls hæmorrhage in ophthalmic and nasal surgery (1 of adrenaline in 5000). As an addition to eye lotions in conjunctivitis, 1 of adrenaline in 4000 is sufficient. Adrenaline may be used also in the form of suppositories or ointment for its constrictive action upon hæmorrhoids and other inflammatory conditions of the anus and rectum. The constricting effect of adrenaline on mucous membrane may be prolonged if ephedrine is employed at the same time, as in Nebula Adrenalinæ et Ephedrinæ.

Dose.—0.0001 to 0.0005 grammes ($\frac{1}{1000}$ to $\frac{1}{200}$ gram), by subcutaneous injection.

Preparations

Insufflatio Adrenalinæ, B.P.C.—(Insuff. Adrenal.)—Adrenaline Insufflation.

Syn.—Adrenaline Snuff. Adrenaline, about 1 in 1300, with boric acid, camphor, menthol, potassium chlorate, oil of eucalyptus and lycopodium.

Liquor Adrenalinæ Hydrochloridi, B.P.—(Liq. Adrenal. Hydrochlor.)—

Solution of Adrenaline Hydrochloride. *Syn.*—Liquor Adrenalinæ Hydrochloricus; Hydrochloric Solution of Adrenalin. A sterile preparation containing adrenaline, 1 in 1000, dilute hydrochloric acid, chlorbutol and sodium chloride in distilled water. It should be stored in well-filled, well-closed containers in a cool place away from light. The containers should comply with the tests for limit of alkalinity of glass. *Dose.*—0.12 to 0.5 millilitre (2 to 8 minims), by subcutaneous injection.

Nebula Adrenalinæ Aromatica, B.P.C.—(Neb. Adrenal. Aromat.)—Aromatic

Adrenaline Spray. *Syn.*—Adrenaline Inhalant; Aromatic Solution of Adrenaline. Adrenaline, 1 in 1000, with acidified dehydrated alcohol, eucalyptol, oil of sweet birch, castor oil and arachis oil.

Nebula Adrenalinæ et Cocainæ, B.P.C.—(Neb. Adrenal. et Cocain.)—

Adrenaline and Cocaine Spray. Adrenaline, as solution of adrenaline hydrochloride, 1 in 5000, cocaine hydrochloride, 1 in 100, with chlorbutol and sodium chloride, in distilled water.

Nebula Adrenalinæ et Ephedrinæ, B.P.C.—(Neb. Adrenal. et Ephed.)—

Adrenaline and Ephedrine Spray. Adrenaline, as solution of adrenaline hydrochloride, 1 in 8000, and ephedrine hydrochloride, about 1 in 45, with glycerin of phenol and cinnamon water.

Nebula Adrenalinæ et Ephedrinæ Oleosa, B.P.C.—(Neb. Adrenal. et Ephed.

Oleos.)—Only Adrenaline and Ephedrine Spray. Adrenaline, 1 in 10,000, and ephedrine, 1 in 50, with menthol and eucalyptol, in acidified dehydrated alcohol, castor oil and arachis oil.

Suppositorium Adrenalinæ, B.P.C.—(Supp. Adrenal.)—Adrenaline Suppository. Each suppository contains $\frac{1}{60}$ grain of adrenaline.

Suppositorium Adrenalinæ et Cocainæ, B.P.C.—(Supp. Adrenal. et Cocain.)—Adrenaline and Cocaine Suppository. Each suppository contains $\frac{1}{60}$ grain of adrenaline and $\frac{1}{4}$ grain of cocaine hydrochloride.

Unguentum Adrenalinæ, B.P.C.—(Ung. Adrenal.)—Adrenaline Ointment. Adrenaline, 0·1 per cent., as borate, in hydrous wool fat and white soft paraffin.

Unguentum Adrenalinæ et Amylocainæ Compositum, B.P.C.—(Ung. Adrenal. et Amylocain. Co.)—Compound Ointment of Adrenaline and Amylocaine. Adrenaline, 1 in 14,000, as benzoate, amylocaine hydrochloride and benzocaine, of each 1 per cent., and liquid extract of hamamelis, 7·5 per cent. v/w, in wool fat and yellow soft paraffin.

Unguentum Adrenalinæ et Cocainæ, B.P.C.—(Ung. Adrenal. et Cocain.)—Cocaine and Adrenaline Ointment. Adrenaline, 0·1 per cent., as borate, and cocaine hydrochloride, 1 per cent., in hydrous wool fat and white soft paraffin.

ÆTHER

(Æther)

Ether

Ether is diethyl ether, $(\text{C}_2\text{H}_5)_2\text{O}$, and may be obtained by the distillation of a mixture of ethyl alcohol and sulphuric acid, and rectification of the distillate. It is a colourless, transparent, very mobile liquid, with a characteristic odour and a sweet burning taste. It is very volatile and inflammable, and mixtures of its vapour with oxygen, nitrous oxide, or air in certain proportions are explosive. The flash-point is about -20° (close test).

Methylated ether for various technical purposes is prepared from duty-free alcohol and subsequently denatured by the addition of wood naphtha, or from industrial methylated spirits. The ether thus obtained is adjusted to the required specific gravity, which varies between wide limits, generally from 0·720 to 0·750, by the addition of alcohol and water in varying proportions. Methylated ether is unsuitable for anæsthetic purposes or oral administration. Ether should be **stored** in well-closed containers, protected from light and in a cool place.

Soluble in water (1 in $8\frac{1}{2}$); miscible in all proportions with alcohol (90 per cent.), chloroform, and fixed and volatile oils.

Standard, B.P.—Ether has a boiling-range of 34° to 36° and a specific gravity of 0·720 to 0·724. Residue on evaporation, not more than 0·002 per cent. w/v. It complies also with limit tests for sulphurous acid and other free acids, and for peroxides.

Action and Uses.—Ether is employed internally for its action on the stomach and circulation. Taken by the mouth, it has a narcotic action somewhat similar to that of alcohol, except that the intoxication comes on and passes away much more rapidly, so that a person may

become intoxicated with ether and recover three or four times a day. In the stomach it acts as a carminative and reflexly excites the heart, but it has little or no direct action on either the heart or blood vessels.

Ether is **administered** in mixtures in the form of Spiritus Ætheris or Spiritus Ætheris Compositus, or in gelatin capsules containing 0·18 or 0·3 millilitre (3 or 5 minims). Hypodermic injections, 1 to 2 millilitres (15 to 30 minims), are used as a restorative in collapse; for this purpose Injectio Camphoræ Æthereæ is used. Ether containing one-fourth to one-half its volume of olive oil is administered also as a rectal injection to produce anæsthesia.

As a local anæsthetic the ether spray has been used for small and superficial operations, but its use in this manner has been almost entirely superseded by that of ethyl chloride. Ether is used to cleanse skin areas before surgical operations either alone or in conjunction with soap (Liquor Saponis Æthereus). It is also employed as a menstruum for exhausting such drugs as male fern and capsicum, and as a solvent for oils, resins and many other substances. Ether for **injection** should be filled into sterile containers under aseptic conditions.

Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

Preparations

Injectio Camphoræ Æthereæ, B.P.C.—(Inj. Camph. Æther.)—Ethereal Injection of Camphor. *Syn.*—Curschmann's Solution. Camphor, 1 in 5, and ether, about 1 in 3, in olive oil. **Dose.**—0·25 to 1 millilitre (4 to 15 minims), by subcutaneous injection.

Mistura Ætheris cum Ammonia, B.P.C.—(Mist. Æther. c. Ammon.)—Ether Mixture with Ammonia. One fluid ounce contains 30 minims each of spirit of ether and aromatic spirit of ammonia, in camphor water. **Dose.**—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Spiritus Ætheris, B.P.—(Sp. Æther.)—Spirit of Ether. Ether, 33 per cent. v/v in alcohol (90 per cent.). Specific gravity, 0·802 to 0·806. **Dose.**—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

Spiritus Ætheris Compositus, B.P.C.—(Sp. Æther. Co.)—Compound Spirit of Ether. *Syn.*—Hoffmann's Anodyne. An alcoholic solution containing about 1 in 8 of ether, with ethyl sulphate and ethyl hydrogen sulphate. **Dose.**—For a single administration, 4 to 6 millilitres (1 to 1 $\frac{1}{2}$ fluid drachms); for repeated administration, 1·2 to 2·5 millilitres (20 to 40 minims).

ÆTHER ANÆSTHETICUS

(Æther Anæsth.)

Anæsthetic Ether

Synonyms—Æther Purificatus; Purified Ether.

Anæsthetic ether is a highly purified grade of ether. It should be **stored** in a dry container closed with a well-fitting glass stopper or a cork covered with tin-foil, protected from light and in a cool place.

Standard, B.P.—Anæsthetic ether has a boiling-range of 34° to 35° and a specific gravity of 0.720. No foreign odour is detectable when it is allowed to evaporate spontaneously from filter paper and it complies also with a test for the absence of methyl alcohol and with limit tests for peroxides and for acetone and aldehyde.

Action and Uses.—Anæsthetic ether is employed for inhalation as a general anæsthetic. For this purpose, it is only about one-fourth as toxic to the central nervous system as chloroform. The cases of sudden death from vagal stimulation in the early stages of chloroform narcosis are unknown in ether narcosis. The disadvantages of ether are the time taken in inducing anæsthesia, the stage of excitement being especially prolonged, and its irritation to the bronchial mucous membrane. A hypodermic injection of atropine, with or without morphine and hyoscine, is frequently given before administration of ether. When employed as a general anæsthetic, its use is sometimes preceded by administration of nitrous oxide.

ÆTHYLENI DICHLORIDUM

(Æthylen. Dichlor.)

Ethylene Dichloride

Synonym—Dichlorethane.

Ethylene dichloride, $(\text{CH}_2\text{Cl})_2$, may be prepared by passing ethylene into a slightly warmed mixture of 2 parts of manganese dioxide, 3 parts of sodium chloride, 4 parts of water and 5 parts of sulphuric acid. It may be purified by washing with a dilute solution of sodium carbonate, drying over calcium chloride and distilling. It is a mobile liquid, with an ethereal odour and sweetish taste. Ethylene dichloride dissolves iodine, forming a reddish-violet solution. It does not decolourise potassium permanganate solution. It boils at about 84° and has a specific gravity of about 1.26.

Soluble in water (about 1 in 120).

Action and Uses.—Ethylene dichloride is employed as a solvent; a solution of iodine, 1 in 40, in ethylene dichloride has been used as an application to the skin in place of weak solution of iodine.

ÆTHYLENI DIBROMIDUM.—Ethylene dibromide, $(\text{CH}_2\text{Br})_2$, may be prepared by heating ethyl bromide with bromine in the presence of iron wire, or by the combination of ethylene with bromine, and occurs as a heavy, colourless liquid with a characteristic odour. When placed in a freezing mixture it solidifies, melting again at about 9°; boiling-point, about 131°; specific gravity, about 2.18. It is slightly soluble in water and miscible with alcohol, ether and oils.

ÆTHYLENUM

(Æthylen.)

Ethylene

Ethylene, $\text{CH}_2:\text{CH}_2$, may be obtained from the decomposition products of petroleum and is usually supplied compressed in metal cylinders. It is a colourless gas with a faint, sweetish odour and taste, burning in air with a luminous flame and forming explosive mixtures with various proportions of air or oxygen. It is absorbed slowly by sulphuric acid but rapidly by fuming sulphuric acid with formation of ethyl hydrogen sulphate, $(\text{C}_2\text{H}_5)\text{HSO}_4$; it is also absorbed by potassium permanganate solution with formation of ethylene glycol, $\text{C}_2\text{H}_4(\text{OH})_2$, and it discharges the colour of bromine water.

Slightly **soluble** in water (1 in 9.2 at 25°); soluble in alcohol (95 per cent.) (2 in 1 at 25°) and ether (20 in 1 at 15.5°).

Standard, B.P.—Ethylene contains not less than 98 per cent. v/v of C_2H_4 . It complies with tests for the absence of carbon monoxide and with limit tests for carbon dioxide, acid and sulphur dioxide, and for acetylene, phosphine, aldehydes and hydrogen sulphide.

Action and Uses.—As a general anæsthetic, ethylene is administered in admixture with oxygen in the proportion of 80 to 90 per cent. of ethylene. Anæsthesia is quickly produced without any respiratory difficulty, and, on withdrawing the anæsthetic, recovery is rapid, the patient generally waking without excitement and with comparatively little tendency to vomit. Ethylene-oxygen anæsthesia is suitable for most major operations since the muscular relaxation produced is superior to that obtained by nitrous oxide-oxygen, but not so complete as that produced by ether. For this reason it is necessary to supplement its action with a small amount of ether when operating on the upper abdomen. The general tissues of the body are unaffected by its use, and it produces no alteration in the clotting time of the blood. The undesirable effect on kidney function is less than that of ether, and there is a marked absence of post-operative pneumonia. It is considered the best anæsthetic for cases attended with risk. The disadvantage of ethylene is the danger of fire or explosion. Consequently it should not be used in the neighbourhood of a naked flame or in operations where cautery, diathermy or any form of electric apparatus which produces a spark is to be employed. Ethylene is also used for ripening fruit during transit. Fruit so ripened does not contain the same amount of vitamins as that which is ripened naturally, but the vitamins already present are not affected.

ACETYLENUM.—A mixture of acetylene, $\text{CH}:\text{CH}$, 40 to 80 per cent., with oxygen has been suggested as a general anæsthetic. It is considered to be rapid and safe in its action, but the dangers of explosion impose considerable limits on its use.

ÆTHYLHYDROCUPREINÆ HYDROCHLORIDUM

(Æthylhydrocuprein. Hydrochlor.)

Ethylhydrocupreine Hydrochloride

Ethylhydrocupreine hydrochloride is the hydrochloride of an alkaloid which may be prepared synthetically by the ethylation of the hydrocupreine produced by the demethylation of hydroquinine, the product of the hydrogenation of quinine. It occurs as a white, crystalline powder, with a very bitter taste and melting at about 240° .

Readily **soluble** in water, alcohol and chloroform.

Standard.—Ethylhydrocupreine hydrochloride contains not less than 90 per cent. of $\text{C}_{21}\text{H}_{28}\text{O}_2\text{N}_2$. On the addition of excess of sodium hydroxide solution to 0.5 gramme in 5 millilitres of water, a white, curdy precipitate is produced (distinction from hydrocupreine). On the addition of 0.3 millilitre of N/10 potassium permanganate to 0.1 gramme, dissolved in 20 millilitres of water at 15° , a violet colour is produced and persists for at least one minute (limit of quinine and other impurities). 0.5 gramme dissolves in 1 millilitre of sulphuric acid with not more than a slightly greenish-yellow colour (limit of organic impurities).

Assay.—Dissolve about 0.5 gramme, accurately weighed, in 20 millilitres of water in a separator, make slightly alkaline with dilute solution of ammonia and completely extract with successive portions of chloroform, passing each portion of chloroform through 10 millilitres of water contained in a second separator; evaporate the combined chloroform extracts, add 2 millilitres of alcohol and again evaporate; dry the residue of $\text{C}_{21}\text{H}_{28}\text{O}_2\text{N}_2$ to constant weight at 100° .

Action and Uses.—Ethylhydrocupreine hydrochloride exerts a specific bactericidal action upon the pneumococcus and is used for local application in the treatment of pneumococcal infections of the eyes, where it is said to be capable of killing the pneumococcus in the substance of the cornea without injuring the cornea itself. It is not suitable for oral administration in the treatment of pneumonia; for this purpose, ethylhydrocupreine base is employed. A solution containing 1 or 2 per cent. of ethylhydrocupreine hydrochloride may be instilled into the conjunctival sac, or an ointment with atropine sulphate in yellow soft paraffin may be applied. The first application of the solution is often painful, but anaesthesia develops in from two to thirty seconds, and persists sufficiently long to prevent discomfort from subsequent applications. Ethylhydrocupreine is employed as a prophylactic against infection after injuries to the eye involving laceration of the cornea. It may also be used in 0.01 per cent. w/v solution in water as a mouth-wash or gargle. Solutions for **injection** may be sterilised by tyndallisation or by filtration. The containers must comply with the tests for limit of alkalinity of glass, and the solution should be stored protected from light.

ÆTHYLHYDROCUPREINÆ.—Ethylhydrocupreine, $C_{21}H_{28}O_2N_2$, occurs as a white powder or in minute crystals, melting at about 124° , readily soluble in alcohol, chloroform, ether and dilute acid, and insoluble in water. Ethylhydrocupreine exerts a powerful and selectively specific bactericidal action against all four types of the pneumococcus, and has been recommended for use as a curative agent in pneumococcal infection and as a prophylactic in impending pneumonia. It kills the pneumococcus in a dilution of 1 in 400,000 *in vitro*, but for other bacteria the solution must be from 100 to 1000 times stronger to produce a comparable effect. Following oral administration of ethylhydrocupreine the blood serum acquires pneumococcicidal properties. Ethylhydrocupreine base, but not the hydrochloride, is suitable for use in the treatment of pneumonia. Treatment should be commenced if possible within forty-eight hours after the initial symptoms. For adults, doses of 0.25 gramme (4 grains) should be given orally at intervals of five hours night and day for three days only, and 5 ounces of milk given with each dose. Patients who exhibit an idiosyncrasy towards quinine may show a similar idiosyncrasy towards ethylhydrocupreine. Disturbances of hearing, such as a ringing in the ears, or dulled vision are indications for its discontinuance. The administration of milk with each dose serves not only to supply nourishment, but also to utilise free hydrochloric acid in the stomach, thereby retarding the too rapid conversion of the base into the more soluble hydrochloride. In this way the rate of absorption is so controlled that an optimum concentration is more easily maintained in the blood. The administration of ethylhydrocupreine requires caution since large doses or continued administration may cause optic atrophy; the vision should be carefully tested throughout the treatment. Dose.—0.25 gramme (4 grains).

AMYLYHYDROCUPREINÆ DIHYDROCHLORIDUM.—*iso*Amylhydrocupreine dihydrochloride, $C_{24}H_{34}O_2N_2 \cdot 2HCl$, is the salt of the synthetic base. It is a white, crystalline powder, sparingly soluble in water and readily soluble in alcohol. It has been suggested for use as an antiseptic and anæsthetic in diphtheria and other affections of the nose and throat, and for anæsthesia of the bladder.

OCTYLHYDROCUPREINÆ DIHYDROCHLORIDUM.—*iso*Octylhydrocupreine dihydrochloride, $C_{27}H_{38}O_2N_2 \cdot 2HCl$, is the salt of the synthetic base. It is a white powder, sparingly soluble in water and soluble in alcohol. It is suggested as a disinfectant for wounds and is used in solution containing 0.5 to 1 per cent. w/v.

ÆTHYLIS ACETAS

(Æthyl. Acet.)

Ethyl Acetate

Synonyms—Ether Aceticus; Acetic Ether.

Ethyl acetate, $CH_3 \cdot COOC_2H_5$, mixed with small quantities of alcohol and other substances, is obtained by distilling ethyl alcohol, sulphuric acid and acetic acid, and purifying the product. It occurs as a colourless liquid, with a characteristic, fragrant odour. In the presence of water it becomes partially hydrolysed with formation of ethyl alcohol and acetic acid; conversely, it is produced in mixtures containing alcohol and acetic acid. Ethyl acetate prepared from industrial methylated spirit is used as a solvent, for technical purposes. It should be **stored** in well-stoppered bottles.

Soluble in water (1 in 15); miscible with alcohol, ether and chloroform.

Standard.—Ethyl acetate contains not less than 90 per cent. w/w of $C_4H_8O_2$. Specific gravity, 0.900 to 0.907. Residue on evaporation, not more than 0.05 per cent. Moistened blue litmus paper, introduced into the liquid, is not immediately reddened (limit of free acid). When carefully poured over sulphuric acid in a test tube, no dark ring is formed at the point of contact within fifteen minutes (limit of readily carbonisable substances). Mix about 2 millilitres with 20 millilitres of sodium hydroxide solution and distil 5 millilitres; the distillate complies with the limit test for methyl alcohol in Alcohol.

Assay.—Weigh accurately about 5 grammes in a tared flask and dilute to 100 millilitres with water. Take 10 millilitres of this solution and neutralise with N/1 sodium hydroxide, using phenolphthalein as indicator; add 20 millilitres of N/1 sodium hydroxide, mix, set aside for thirty minutes, and titrate with N/1 sulphuric acid; each millilitre of N/1 sodium hydroxide is equivalent to 0.08806 gramme of $C_4H_8O_2$.

Action and Uses.—Ethyl acetate is carminative, antispasmodic and diaphoretic, but is seldom given internally. For inhalation in laryngeal catarrh, 2 millilitres ($\frac{1}{2}$ fluid drachm) is added to 600 millilitres (1 pint) of water at 60°. Ethyl acetate is widely used as a solvent.

Dose.—For repeated administration, 1 to 2 millilitres ($\frac{1}{4}$ to $\frac{1}{2}$ fluid drachm); for a single administration, 3 to 4 millilitres ($\frac{3}{4}$ to 1 fluid drachm).

BENZYLIS ACETAS.—Benzyl acetate, $CH_3COOCH_2C_6H_5$, is present in the oils of hyacinth, jasmin and other flowers and may be obtained by the acetylation of benzyl alcohol. It occurs as a colourless liquid with a sweet, jasmin-like odour, having a specific gravity of about 1.06 and a boiling-point of about 216°. It is used in perfumery.

BUTYLIS ACETAS.—*n*-Butyl acetate, $CH_3COO(CH_2)_3CH_3$, may be prepared by the acetylation of butyl alcohol and occurs as a colourless, non-toxic liquid having an odour similar to, but less pronounced than, that of amyl acetate. It has a specific gravity of about 0.875 to 0.890 and a boiling-range of about 110° to 130°. It is miscible with oils and hydrocarbons, and is used as a solvent in the manufacture of lacquers and varnishes.

ÆTHYLIS BROMIDUM

(Æthyl. Brom.)

Ethyl Bromide

Ethyl bromide may be prepared by distilling a mixture of alcohol, potassium bromide and sulphuric acid. To prevent decomposition about 1 per cent. of alcohol is added to the purified product. It occurs as a clear, colourless, strongly refracting, neutral liquid, with a pleasant, ethereal odour and a sweetish, warm taste. Boiling-point, about 38°. It is decomposed by exposure to air and sunlight, and should be **stored** in well-closed bottles in a dark place.

Soluble in water (about 1 in 100), alcohol and ether.

Standard.—Ethyl bromide has a specific gravity of 1·453 to 1·457. Sulphuric acid, shaken with an equal volume of ethyl bromide in a glass-stoppered vessel and allowed to stand for one hour in the dark, does not acquire a yellow colour (limit of foreign organic matter). When allowed to evaporate spontaneously, no foreign odour is perceptible and no appreciable residue remains (limit of phosphorus compounds). When 10 millilitres is shaken with 10 millilitres of 20 per cent. cadmium iodide solution and 1 millilitre of starch mucilage, no colour is produced in either layer (limit of free bromine). When 5 millilitres is shaken with 5 millilitres of water, and the water separated, not more than 0·5 millilitre of N/10 sodium hydroxide is required to neutralise the aqueous solution to phenolphthalein (limit of hydrobromic acid).

Action and Uses.—Ethyl bromide has been used instead of chloroform as an anæsthetic in short operations. Consciousness returns very rapidly, but there is sometimes an after-feeling of discomfort. It may seriously depress the respiration and several deaths have resulted from its use as an anæsthetic.

ÆTHYLIS IODIDUM.—Ethyl iodide, C_2H_5I , occurs as a clear, colourless, mobile liquid, with a pleasant, ethereal odour, and a pungent taste. It is decomposed on exposure to air and sunlight, and should be stored in well-closed bottles in a dark place. Boiling-point, 71° to 72° ; specific gravity, about 1·943. It is soluble in water (1 in 440), and miscible in all proportions with alcohol and ether. Ethyl iodide has been used alone or with two parts of chloroform for inhalation to relieve the dyspnoea of bronchial asthma and oedematous laryngitis. Dose.—0·2 to 0·3 millilitre (3 to 5 minims), by inhalation.

ÆTHYLIS CHLORIDUM

(Æthyl. Chlor.)

Ethyl Chloride

$C_2H_5Cl = 64\cdot50$

Ethyl chloride or monochlorethane, $CH_3\cdot CH_2Cl$, may be prepared by the action of hydrogen chloride on ethyl alcohol or on industrial methylated spirit; if prepared from methylated spirit it will contain a small proportion of methyl chloride. It occurs as a gas at ordinary temperatures and pressures, but is liquefied by slight compression, forming a colourless, mobile and very volatile liquid, in which form it is usually supplied; under normal pressure the liquid boils at about $12\cdot5^\circ$ and has a specific gravity ($0^\circ/15\cdot5^\circ$) of about 0·921. It has a pleasant, ethereal odour and a sweetish, burning taste. It is highly inflammable, burning with a smoky, green-edged flame. Ethyl chloride may be identified by hydrolysis with sodium hydroxide, when sodium chloride and ethyl alcohol are formed. The official assay gives very low

results; accurate results may be obtained by using an excess of N/1 alcoholic potassium hydroxide and making a blank experiment.

Slightly **soluble** in water; miscible with alcohol (90 per cent.) and ether.

Standard, B.P.—Ethyl chloride contains the equivalent of not less than 99.5 per cent. w/w of C_2H_5Cl . Residue on evaporation, not more than 0.01 per cent. During evaporation no foreign odour is at any time detectable. It complies also with limit tests for acid, alkali, ionisable chlorides and ethyl alcohol.

Action and Uses.—Ethyl chloride is largely used to produce local or general anæsthesia in minor surgery. For local use, the tubes in which the liquid is stored are provided with a tap by which a fine jet of the liquid is directed upon the part, at a distance of six to eight inches. For general anæsthesia, the vapour volatilising from the liquid is inhaled through a mask and sometimes perfumed with cologne essence. Anæsthesia is rapid, but difficult to maintain for long with safety. Ethyl chloride has been recommended for use in place of nitrous oxide, and it is sometimes used to produce primary anæsthesia before giving ether or chloroform, especially to children. For a sedative inhalation, glass capsules encased in silk are prepared containing 0.3 millilitre (5 minims) in each. In cases of collapse from administration of ethyl chloride the restorative measures recommended under Chloroformum should be applied.

METHYLIS CHLORIDUM.—Methyl chloride, CH_3Cl , occurs, in the compressed state, as a colourless liquid having an ethereal odour and a sweet taste. At about -25° it has a specific gravity of 0.991; boiling-point, about -21° . It is soluble in water, more so in alcohol and freely in ether and chloroform. Methyl chloride is occasionally used to produce local anæsthesia, the spray being directed obliquely upon the part, which may be partly protected by a thin layer of cotton wool, as the liquid is liable to cause blisters. In neuralgia, sciatica and lumbago, cotton wool soaked in liquid methyl chloride may be applied to the seat of pain. On account of its action on the skin, however, pure methyl chloride is not much used as a local anæsthetic; a mixture of methyl and ethyl chlorides, which is free from this disadvantage, is sometimes used.

ÆTHYLMORPHINÆ HYDROCHLORIDUM

(Æthylmorph. Hydrochlor.)

Ethylmorphine Hydrochloride

Ethylmorphine hydrochloride may be obtained by the action of diethyl sulphate on morphine in alkaline alcoholic solution, the ethylmorphine formed being neutralised with hydrochloric acid. It occurs as a white, odourless, minutely crystalline powder, having a bitter taste. Its aqueous solution is precipitated by the usual alkaloidal reagents. Melting-point, about 123° . The addition of one drop of

ferric chloride solution to a solution of 0.01 gramme in 10 millilitres of sulphuric acid, produces on warming a violet or blue colouration, and the further addition of one drop of nitric acid changes it to deep red.

Soluble in water (about 1 in 10), alcohol (about 1 in 25), warm alcohol (about 1 in 1); almost insoluble in ether and chloroform.

Standard.—Ethylmorphine hydrochloride loses, on drying at 100°, not more than 10 per cent. of its weight. Ash, not more than 0.1 per cent. A solution in water (1 in 20) is neutral to litmus paper. On the addition of 1 millilitre of dilute solution of ammonia to 5 millilitres of a 4 per cent. w/v solution in water, a white turbidity is immediately produced (distinction from codeine hydrochloride). To 5 millilitres of a 2 per cent. w/v solution in N/10 hydrochloric acid add 2 millilitres of a 1 per cent. w/v solution of sodium nitrite in water and then 3 millilitres of dilute solution of ammonia; the yellow colour produced is not deeper than that obtained when 5 millilitres of a 0.002 per cent. w/v solution of anhydrous morphine in N/10 hydrochloric acid is similarly treated (limit of morphine).

Action and Uses.—Ethylmorphine hydrochloride is intermediate in its properties between morphine and codeine. It does not depress the respiratory centre to the same extent as does morphine. It is employed to allay cough in bronchitis, bronchial asthma and whooping cough, but is inferior to diamorphine. It is narcotic and sedative, and is sometimes employed for ulcer and cancer of the stomach and bowel when morphine causes nausea. It is employed in ophthalmic practice as an analgesic in corneal ulceration, iritis and glaucoma (1 to 5 per cent. solution). Its use may at first cause a sharp burning sensation and some œdema of the conjunctiva, which, however, soon subsides. It may be **administered** as an elixir or in pills. Solutions for **injection** may be sterilised by tyndallisation or by filtration. The containers must comply with the tests for limit of alkalinity of glass, and the solution should be stored protected from light.

Dose.—0.006 to 0.03 gramme ($\frac{1}{16}$ to $\frac{1}{2}$ grain), by the mouth; 0.0025 to 0.008 gramme ($\frac{1}{40}$ to $\frac{1}{8}$ grain), by hypodermic injection.

BENZYLMORPHINE HYDROCHLORIDUM.—Benzylmorphine hydrochloride, $C_{17}H_{18}O_2N(OCH_2C_6H_5)$, HCl, is a salt of a base formed by the action of benzyl chloride on morphine. It occurs as a colourless, microcrystalline powder, having a bitter taste. This ether must not be confused with the ester, benzoylmorphine. Benzylmorphine hydrochloride is soluble in water (1 in 200), in alcohol (1 in 160), but insoluble in ether and chloroform. Benzylmorphine has properties closely resembling those of codeine and ethylmorphine, and may be used for local irritation of the respiratory organs. It is generally administered for this purpose in solution with expectorants. Dose.—0.008 to 0.03 gramme ($\frac{1}{8}$ to $\frac{1}{2}$ grain).

Preparation

Elixir Æthylmorphinæ et Terpinæ, B.P.C.—(Elix. Æthylmorph. et Terpin.)—Elixir of Ethylmorphine and Terpin. Each fluid drachm contains approximately $\frac{1}{4}$ grain of ethylmorphine hydrochloride and $\frac{1}{8}$ grain of terpin hydrate, with alcohol (90 per cent), glycerin and syrup of wild cherry. Dose.—2 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

AGAR

(Agar)

Agar*Synonyms*—Agar-Agar; Japanese Isinglass.

Agar is the solid residue obtained by concentrating a decoction prepared from *Gelidium corneum* (Huds.) Lamouroux, *G. cartilagineum* Gaill. (Fam. Gelidiaceæ) and other algæ belonging to the Rhodophyceæ. The seaweeds are collected chiefly off the coast of Japan, bleached by exposure to the sun and boiled in slightly acidulated water. The strained decoction is exposed to a low atmospheric temperature to freeze out the water and the gelatinous slabs so produced are cut up, converted into fine strips by forcing them through wire netting, and dried.

Agar occurs as thin, translucent strips about 60 centimetres long and 4 millimetres wide, of a greyish-white colour, with a somewhat crinkled and micaceous surface, or as flattened bands about 30 centimetres long and 2.5 centimetres wide and of a yellowish colour. On hydrolysis with 5 per cent. v/v sulphuric acid, agar yields galactose which reduces Fehling's solution, thus distinguishing it from gelatin and isinglass. The latter substances yield ammonia when heated with soda lime, a reaction which is not given by agar. A nearly boiling 0.2 per cent. solution of agar in water gives with solution of tannic acid a faint opalescence but no precipitate; a similar cold solution, however, yields a precipitate with solution of tannic acid. One drop of N/10 iodine added to 10 millilitres of a rapidly cooled 0.2 per cent. aqueous solution produces a pale yellowish colour, while 0.5 millilitre added to a similar solution yields a dark purple colouration; when the hot solution is allowed to cool slowly and 0.5 millilitre of N/10 iodine is added after the solution has been set aside for two hours, a brownish colour is produced. The residue obtained by treating the ash, particularly of strip agar, with hydrochloric acid exhibits, when viewed microscopically, particles of sand, sponge spicules and diatoms, of which the disc-shaped species, *Arachnoidiscus Ehrenbergii* Baill., is one of the best known. When immersed in cold water, agar swells to a gelatinous mass, but does not dissolve; a 1 per cent. solution in water forms a firm jelly.

Agar **contains** the carbohydrate, gelose, in combination with calcium and sulphuric acid in the form of an ethereal sulphate. Agar also contains small traces of boron and arsenic.

Standard, B.P.—Agar yields not more than 5 per cent. of ash.

Agar, in powder (Pulvis Agar : Pulv. Agar), contains the constituents and possesses the properties of Agar, and complies with the standard for the unground drug. When viewed microscopically, it shows translucent rounded or angular fragments; no starch grains are present.

Action and Uses.—Agar has little nutritive value; it is not attacked by the digestive secretions and passes through the intestine almost

unchanged. It absorbs and retains moisture, increasing very largely in bulk, and, owing to this property, it is used with success in chronic constipation with intestinal atony. It renders the fæces soft and bulky and promotes peristalsis. Emulsions containing agar with liquid paraffin, phenolphthalein and magnesium hydroxide are also used. When agar is to be taken by itself, small shreds mixed with fruit, milk, etc., are preferable. A jelly for invalids may be made by dissolving 1 part of agar in 200 parts of boiling water and allowing to cool. Biscuits made from a mixture of agar and bran are given to diabetic patients. Agar is employed for preparing culture media for use in bacteriology; it has also been recommended as a substitute for gelatin in making suppositories and for use as an emulsifying agent.

Dose.—4 to 16 grammes (1 to 4 drachms).

Preparations

Emulsio Paraffini Liquidi Composita, B.P.C.—(Emuls. Paraff. Liq. Co.)—Compound Emulsion of Liquid Paraffin. *Syn.*—Emulsion of Liquid Paraffin with Agar and Phenolphthalein. Emulsion of liquid paraffin with agar, containing $1\frac{1}{2}$ grains of phenolphthalein in each fluid ounce. **Dose.**—4 to 16 millilitres (1 to 4 fluid drachms).

Emulsio Paraffini Liquidi cum Agar, B.P.C.—(Emuls. Paraff. Liq. c. Agar)—Emulsion of Liquid Paraffin with Agar. It contains 50 per cent. v/v of liquid paraffin, with agar. **Dose.** 4 to 16 millilitres (1 to 4 fluid drachms).

AGARICUS

(Agaric.)

Agaric

Synonyms.—White Agaric; Larch Agaric; Purging Agaric; Boletus Laricis.

Agaric is the dried fungus, *Fomes officinalis* Faull. (Fam. Polyporaceæ), which grows in Europe and Northern Asia upon *Larix sibirica* Led., *L. europæa* DC., and other species of *Larix* (Fam. Pinaceæ). It is collected in August and September, chiefly in the larch forests of the French Alps and Southern Tyrol, and near Archangel; it is dried and bleached in the sun. Agaric should not be confused with the poisonous fly agaric, *Amantia muscaria* Pers., which is the Agaricus of the Homœopathic Pharmacopœia.

The fungus occurs in spongy, resinous masses of irregular shape, brownish externally and yellowish-white internally. The pieces are friable, not easily powdered in a mortar, but can be disintegrated by rubbing through a sieve. The odour is faint and meal-like and the taste sweetish, afterwards acrid and bitter, resembling that of quinine. Microscopically it consists of long, slender, interlacing hyphæ 3 to 5 microns wide, with occasional enlargements and calcareous particles of irregular shape, and a few prismatic crystals of calcium oxalate.

Agaric contains agaric acid, agaricol, a phytosterol, ricinoleic acid, cetyl alcohol, and several resinous principles.

Standard.—Acid-insoluble ash, not more than 2 per cent.

Action and Uses.—Agaric is an irritant and may cause nausea, vomiting and purging. It is used in the preparation of *Tinctura Antiperiodica*.

Dose.—0.2 to 2 grammes (3 to 30 grains).

AGROPYRUM

(*Agropyri*.)

Couch Grass

Synonyms—*Triticum*; *Triticum repens*.

Couch grass is the rhizome of *Agropyron repens* Beauvois (Fam. Gramineæ), a weed abundant in Europe, Northern Asia, Australia and America. It is gathered in the spring, deprived of its roots, cut into short lengths and dried.

The rhizome occurs in short, straight pieces, hollow except at the nodes, about 3 to 20 millimetres long and 2 to 3 millimetres in diameter, straw-coloured, lustrous and strongly furrowed longitudinally. At the nodes are small, circular, root scars and somewhat larger stem scars; very short pieces of stem or root are sometimes attached. It has no odour and possesses a faint, sweetish taste. A transverse section is circular in outline.

The diagnostic **microscopical** characters are the narrow hypodermal band of sclerenchyma; nearer the centre, a wide band of sclerenchyma in which the principal vascular bundles are embedded; in surface view, the epidermis which consists of wavy-walled rectangular cells in parallel rows, in which long cells alternate with small twin cells. The twin cells are together about one-tenth the length of a long cell, the latter being about eleven times as long as it is broad.

Couch grass **contains** triticin (a carbohydrate resembling inulin), dextrose, mucilage, mannitol and inositol. Triticin yields lævulose on hydrolysis. The medicinal activity cannot be attributed to any known constituent.

Substitutes.—The rhizome of *Cynodon Dactylon* Persoon (Dog-grass), has been substituted wholly or in part for the genuine drug; it may be recognised by the presence of abundant starch and the absence of hypodermal sclerenchyma.

Standard.—Couch grass contains not more than 2 per cent. of foreign organic matter. Acid-insoluble ash, not more than 3 per cent.

Couch grass, in powder (*Pulvis Agropyri* : *Pulv. Agropyri*.), contains the constituents and possesses the diagnostic microscopical characters of *Agropyrum*, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Cough grass is a demulcent diuretic and is used internally in the treatment of catarrhal diseases of the genito-urinary tract, in the form of the liquid extract or decoction. The latter is a suitable vehicle for bladder sedatives and antiseptics.

Preparations

Decoctum Agropyri, B.P.C.—(Dec. Agropyr.)—Decoction of Couch Grass. *Syn.*—Decoction of Triticum. 1 in 20. Dose.—15 to 60 millilitres ($\frac{1}{4}$ to 2 fluid ounces).

This decoction was included in the British Pharmacopœia, 1914.

Extractum Agropyri Liquidum, B.P.C.—(Ext. Agropyr. Liq.)—Liquid Extract of Couch Grass. *Syn.*—Liquid Extract of Triticum. 1 in 1. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

This liquid extract was included in the British Pharmacopœia, 1914.

ALBUMEN

(Albumen)

Albumen

Synonyms—Egg Albumen; White of Egg.

Albumen is the liquid white of the egg of *Gallus bankiva* var. *domesticus* (Order Gallinæ). It occurs as a nearly colourless or pale-yellow fluid contained in a network of fibrinous material which is broken up by beating. Albumen should be free from unpleasant odour, and faintly alkaline to litmus. It has a specific gravity of about 1.045 and contains about 13 per cent. of solid matter of which about 12 per cent. is protein. The organic solids contain about 15.5 per cent. of nitrogen and 1.6 per cent. of sulphur. Of the protein, about 6.7 per cent. is globulin (ovoglobulin) and is precipitated by half-saturation with ammonium sulphate; the albumin (ovalbumin) remaining in solution may be salted out by complete saturation with ammonium sulphate.

Albumen is coagulated when heated to about 70°, the temperature of coagulation being influenced by a number of factors, including the rate of heating, the reaction of the solution, and the concentration of electrolytes present. Albumen is coagulated by alcohol. It is precipitated by most mineral acids and some organic acids, but not by phosphoric or acetic acids. It is soluble in caustic alkalis, but forms precipitates with the salts of most of the heavy metals. It is precipitated also by volatile oils, camphor, phenol and tannic acid. Fresh white of egg contains the growth-promoting vitamin B₂, but is lacking in the anti-neuritic vitamin B₁.

Action and Uses.—A solution of albumen made by dissolving the white of one egg in 150 millilitres (5 fluid ounces) of boiled and cooled water, adding salt to taste, and a little brandy if necessary, is used in the diarrhœa of infants. Albumen is used as an antidote to poisoning by mercuric chloride and soluble salts of other heavy metals. It

is also used as a clarifying agent for culture media and gelatin solutions.

ALBUMEN SICCCUM.—Dried albumen may be obtained by careful evaporation of white of egg on glass plates at a temperature not above 50° . It occurs as yellowish, transparent flakes or scales of a horny consistence, or as a coarse powder. It slowly dissolves in about 10 parts of water, being more readily soluble in the presence of a little sodium chloride, forming a solution which may be substituted for white of egg. Dried albumen is used as a protective in colloidal solutions.

OVI VITELLUS.—Yolk of egg is the membranous sac, enclosing a yellow or reddish-yellow, opaque, odourless liquid with a slightly alkaline reaction. The liquid contains about 50 per cent. of water and 20 per cent. of oil, emulsified by the presence of about 7 per cent. of lecithin and 15 per cent. of the protein vitellin. Yolk of egg contains vitamins A, B₁, and B₂. It is employed as an emulsifying agent for oils, being particularly useful in the case of oil of turpentine and other volatile oils.

ALCOHOL

(Alcoh.)

Alcohol (95 per cent.)

Alcohol (95 per cent.) is a mixture of ethyl alcohol, C_2H_5OH , and water obtained by the distillation of fermented saccharine liquids. It occurs as a transparent, colourless, mobile, volatile liquid with a characteristic odour and a burning taste; it is highly inflammable, burning with a blue, smokeless flame.

Miscible in all proportions with water, contraction in volume and rise of temperature occurring, and with ether and chloroform.

Standard, B.P.—Alcohol (95 per cent.) contains not less than 94.7 per cent. v/v or 92.0 per cent. w/w and not more than 95.2 per cent. v/v or 92.7 per cent. w/w of C_2H_6O . Specific gravity, 0.815 to 0.817. Residue on evaporation and drying at 100° , not more than 0.01 per cent. w/v. Refractive index at 20° , 1.3637 to 1.3639. It complies with limit tests for acidity, alkalinity, oily or resinous substances, fusel oil and allied impurities, and aldehyde; it complies also with a test for the absence of methyl alcohol.

DILUTE ALCOHOLS.—Dilute alcohols of various strengths may be prepared by diluting alcohol (95 per cent.) with distilled water in the proportions stated below. Before the final adjustment of volume is made, the mixture is cooled to the same temperature, about 15° , as that at which the alcohol (95 per cent.) is measured. The dilute alcohols comply with the chemical tests for purity of the British Pharmacopœia given under Alcohol, and with specified limits for specific gravity and refractive index.

Alcohol (90 per cent.)—(Spiritus Rectificatus; Rectified Spirit). Dilute 948 millilitres of alcohol (95 per cent.) to 1 litre with distilled water. It contains not less than 89.6 per cent. v/v and not more than 90.5 per cent. v/v of C_2H_6O .

Alcohol (80 per cent.)—Dilute 842 millilitres of alcohol (95 per cent.) to 1 litre with distilled water. It contains not less than 79.5 per cent. v/v and not more than 80.3 per cent. v/v of C_2H_6O .

Alcohol (70 per cent.)—Dilute 737 millilitres of alcohol (95 per cent.) to 1 litre with distilled water. It contains not less than 69.5 per cent. v/v and not more than 70.4 per cent. v/v of C_2H_6O .

Alcohol (60 per cent.).—Dilute 632 millilitres of alcohol (95 per cent.) to 1 litre with distilled water. It contains not less than 59·7 per cent. v/v and not more than 60·2 per cent. v/v of C_2H_5O .

Alcohol (50 per cent.).—Dilute 526 millilitres of alcohol (95 per cent.) to 1 litre with distilled water. It contains not less than 49·6 per cent. v/v and not more than 50·2 per cent. v/v of C_2H_5O .

Alcohol (45 per cent.).—Dilute 474 millilitres of alcohol (95 per cent.) to 1 litre with distilled water. It contains not less than 44·7 per cent. v/v and not more than 45·3 per cent. v/v of C_2H_5O .

Alcohol (25 per cent.).—Dilute 263 millilitres of alcohol (95 per cent.) to 1 litre with distilled water. It contains not less than 24·6 per cent. v/v and not more than 25·4 per cent. v/v of C_2H_5O .

Alcohol (20 per cent.).—Dilute 210 millilitres of alcohol (95 per cent.) to 1 litre with distilled water. It contains not less than 19·5 per cent. v/v and not more than 20·5 per cent. v/v of C_2H_5O .

PROOF SPIRIT.—Proof spirit (*Spiritus Tenuior*) has a specific gravity of 0·9198 and contains about 57·1 per cent. v/v or 49·2 per cent. w/w of C_2H_5O . Spirits are described as so many degrees over or under proof (*o.p.* or *u.p.*) according to the quantity of distilled water which must be added to, or deducted from, 100 volumes of the sample in order to produce spirit of proof strength. Alcohol (90 per cent.) corresponds very nearly to 58 over proof and 100 volumes thus contain almost as much C_2H_5O as 158 volumes of proof spirit.

Action and Uses.—Alcohol produces a purely depressant action on the central nervous system and not, as was formerly supposed, a stimulant effect. This is explained by the fact that the higher centres are inhibitory in action; hence alcohol tends to remove such characteristics as hesitancy, circumspection and self-criticism. Alcohol acts on the digestive system by causing reflexly an increased flow of saliva and gastric juice. It also increases the flow of gastric juice by a direct action on the fundus of the stomach, and further aids digestion by inhibiting unpleasant emotions such as worry or anger. Concentrated solutions of alcohol, however, if taken habitually, produce chronic gastritis with diminished gastric secretion. The clinical picture of cirrhosis of the liver may appear later.

Because of its rapid absorption, alcohol is a valuable food and is used therefore in fevers when the assimilation of ordinary foods is impaired. It should be given in small and repeated doses in order to avoid its action as a tissue poison. Alcohol produces dilatation of the vessels supplying the skin and mucous membranes. Its use should therefore be avoided by those exposed to cold, although it may be of value for restoring the circulation after exposure to cold. It is a hypnotic when given in quiet surroundings conducive to sleep. In the treatment of acute infections, such as pneumonia and septicæmia, alcohol is considered to be of service. Alcohol (80 per cent.), injected into the Gasserian ganglion, is helpful in the treatment of intractable trigeminal neuralgia. Alcohol is excreted partly by the lungs and partly by the kidneys. Chemical estimations of alcohol in the blood, urine, or breath, are sometimes utilised as a test for drunkenness. In the treatment of acute alcoholism the stomach pump should be employed, the stomach being well washed out, and a pint of warm sodium bicarbonate solution left in it. The patient should be kept warm. In chronic alcoholism

in its various manifestations, the only effective action is institutional treatment.

Alcohol may be **administered** in the form of brandy, whisky, or champagne. It is one of the most valuable solvents and preservatives known, and, in appropriate strength, is the menstruum employed in the manufacture of various tinctures, spirits and other galenical preparations. It is also widely used in perfumery and in the manufacture of culinary essences. Diluted alcohol may be used **externally** as an evaporating lotion in various forms of skin inflammation, to diminish sweating, to prevent bed sores, and, in surgery, to sterilise the skin of the patient and the hands of the operator. As, however, industrial methylated spirit and suitable preparations of it are obtainable for these purposes, the use of rectified spirit is not essential. Alcohol hardens by dehydrating, and may therefore be applied to the nipples before lactation. Its greatest bactericidal effect is obtained from a solution containing 70 per cent. of ethyl alcohol.

SPIRITUS FRUMENTI.—Whisky is an alcoholic liquid obtained by distillation from a fermented mash of malted cereal grains, and usually contains about 40 per cent. v/v of C_2H_5OH . It occurs as an amber-coloured liquid, with a distinctive odour and taste, and a slightly acid reaction. It usually contains about 0.1 to 0.2 per cent. of higher alcohols, about 0.03 to 0.08 per cent. of esters, about 0.2 to 0.8 per cent. of volatile acid, about 0.001 to 0.003 per cent. of furfural, and about 0.015 to 0.04 per cent. of other aldehydes, to which secondary products the flavour and odour are due.

SPIRITUS VINI GALICI.—Brandy is obtained by distillation from the wine of grapes, and matured by age. It occurs as a pale, amber-coloured liquid, having a characteristic odour and taste, and, as a rule, a slightly acid reaction. It contains about 40 per cent. v/v of C_2H_5OH . It usually contains about 0.05 to 0.15 per cent. of higher alcohols, about 0.1 to 0.15 per cent. of esters, about 0.05 to 0.2 per cent. of volatile acid, about 0.0005 to 0.002 per cent. of furfural and about 0.02 to 0.04 per cent. of other aldehydes.

The action of brandy and whisky is due mainly to their content of ethyl alcohol. Although the presence of higher alcohols, volatile oils, aldehydes and esters may not be without therapeutic effect, it is not possible in the present state of knowledge to define their pharmacological action. Brandy has the reputation of being of value in the milder forms of diarrhoea and vomiting. As a restorative in syncope it should be given neat, and acts by reflex stimulation of the medulla. In the treatment of acute infections, *e.g.* pneumonia, brandy, 1 ounce, four-hourly for an adult or in smaller doses for children, is of value. By the depressant action on the central nervous system it allays the painful inhibitions to respiration caused by the accompanying pleurisy and so allows of quieter and deeper breathing. Furthermore, and this is of utmost importance in promoting recovery in an acute infection, brandy engenders calm and peaceful sleep. Brandy and whisky are often of benefit in the early stages of a "chill." They act by dilatation of the vessels of the mucous membranes, and the local resistance of the tissue to infection is thereby increased; they should be administered with an equal quantity of water after the patient has retired to bed. The simultaneous administration of a dose of powder of ipecacuanha and opium and acetylsalicylic acid may with advantage be prescribed. Brandy is probably a better hypnotic than whisky; it should be given immediately before retiring. CHAMPAGNE is often of value in checking the toxic vomiting of pregnancy and in sea-sickness, the carbon dioxide acting as a gastric sedative and the alcohol as a food. Champagne is often tolerated better than brandy or whisky in the acute febrile states when toxic gastritis is present. It tends to shorten convalescence in such conditions as post-influenzal debility.

Preparations

Alcohol Ammoniatum, B.P.C.—(Alcoh. Ammon.)—Ammoniated Alcohol. An alcoholic solution of ammonia, containing from 9 per cent. to 11 per cent. w/w of NH_3 .

Lotio Evaporans, B.P.C.—(l.o. Evap.)—Evaporating Lotion. Alcohol, 1 in 8, with ammonium chloride and distilled water.

Mistura Spiritus Vini Gallici, B.P.C.—(Mist. Sp. Vin. Gall.)—Mixture of Brandy. Two fluid ounces contains about 6 fluid drachms of brandy, with yolk of egg, sucrose and cinnamon water. Dose.—(as a draught) 30 to 60 millilitres (1 to 2 fluid ounces).

ALCOHOL AMYLICUM

(Alcoh. Amyl.)

Amyl Alcohol*Synonym*—Amylic Alcohol.

Amyl alcohol is a mixture of approximately 10 per cent. of primary active amyl alcohol (methyl-2-butanol-1) and 90 per cent. of primary isoamyl alcohol (methyl-3-butanol-1) obtained by purifying fusel oil. It occurs as a colourless liquid having a characteristic odour. The flash-point is 19.5° .

Slightly **soluble** in water; miscible in all proportions with alcohol, ether, chloroform, carbon disulphide, light petroleum, benzene, and fixed and volatile oils.

Standard.—Amyl alcohol boils between 128° and 132° . Specific gravity, 0.815 to 0.817. Residue on evaporation, not more than 0.01 per cent. Acidity, calculated as acetic acid, not more than 0.01 per cent. When mixed with an equal volume of sulphuric acid a clear and almost colourless solution is produced.

Action and Uses.—Amyl alcohol has an action very similar to that of ethyl alcohol, but is a more pronounced local irritant. In chronic alcohol poisoning, the deleterious effects are attributed more to amyl alcohol than to ethyl alcohol, but this is not based on satisfactory evidence; the importance of amyl alcohol depends on the fact that small quantities are present in most forms of spirit, especially when these are "raw" or freshly distilled. Amyl alcohol is used chiefly as a solvent.

ALCOHOL DEHYDRATUM

(Alcoh. Dehyd.)

Dehydrated Alcohol*Synonyms*—Alcohol Absolutum; Absolute Alcohol.

Dehydrated alcohol, $\text{CH}_3\cdot\text{CH}_2\text{OH}$, may be obtained by the

dehydration of weaker spirit and subsequent distillation. It possesses the characters of alcohol (95 per cent.), but is very hygroscopic.

Standard, B.P.—Dehydrated alcohol contains not less than 99.4 per cent. v/v or 99 per cent. w/w of C_2H_5O . Specific gravity, 0.7936 to 0.7967. Refractive index at 20° , 1.3614 to 1.3618. It complies with a limit test for water and with the tests for purity for Alcohol.

Action and Uses.—Dehydrated alcohol is used in the preparation of Liquor Æthylis Nitritis and of Liquor Sodii Æthylatis. It is a valuable solvent and dehydrating agent, especially in microscopical technique. It is used in aseptic containers to store surgical needles, sutures, etc., in sterile condition, ready for use. Dehydrated alcohol for **injection** should be filled into sterile containers under aseptic conditions.

Preparation

Liquor Sodii Æthylatis, B.P.C.—(Liq. Sod. Æthylat.)—Solution of Sodium Ethylate. A solution of sodium in dehydrated alcohol, 1 in 20.

ALCOHOL ISOPROPYLICUM

(Alcoh. Isopropyl.)

Isopropyl Alcohol

$C_3H_8O = 60.06$

Isopropyl alcohol, $(CH_3)_2CH \cdot OH$, may be obtained by the reduction of acetone or, as a by-product in the petroleum industry, by absorbing olefine gases containing propylene in sulphuric acid, and hydrolysing the resulting sulphuric acid esters. It is a colourless liquid, with a characteristic alcoholic odour. When heated just to boiling with mercuric sulphate solution, a white or yellow precipitate is formed, and this reaction may be used to distinguish it from methyl and ethyl alcohols. Heated with half its volume of sulphuric acid, propylene is evolved and is readily detected by its characteristic odour. When heated with four volumes of a 10 per cent. potassium dichromate solution and one volume of sulphuric acid, acetone is evolved. Anhydrous isopropyl alcohol has a specific gravity of 0.788 and boils at 82.4° . Isopropyl alcohol, containing water in varying degrees, is also obtainable having specific gravities from 0.793 to 0.795. Technical varieties may contain more than traces of aldehydes and ketones and possess a disagreeable odour and bitter taste.

Miscible with water, but salted out by means of salts or sodium hydroxide.

Standard.—Isopropyl alcohol contains about 96 per cent. v/v, corresponding to about 94 per cent. w/w, of C_3H_8O . Boiling-point

from 80.5° to 81.5°. Specific gravity, 0.810 to 0.812. Residue on evaporation and drying at 100°, not more than 0.01 per cent. To 10 millilitres, diluted with 20 millilitres of water, add 0.5 millilitre of decolourised magenta solution containing 0.1 per cent. of pyrogallol and mix well; no pink colouration is produced within one minute (limit of aldehydes). To 5 millilitres add 2 millilitres of N/1 sodium hydroxide and 5 drops of sodium nitroprusside solution; on slightly acidifying with acetic acid, no violet colour is produced within one minute (limit of ketones).

Action and Uses.—Isopropyl alcohol is twice as toxic as ethyl alcohol when given intravenously to cats, but it is sufficiently non-toxic for external and oral administration in small amounts. Inhalation of its vapour has not been found to cause the defects in vision associated with methyl alcohol. Isopropyl alcohol is not potable and its ingestion produces a form of intoxication which resembles that produced by ethyl alcohol. In concentrations up to 50 per cent., applied externally to open wounds, it allows healing to take place normally. It has been used for skin sterilisation, also in antiseptic solutions for the throat. Isopropyl alcohol may be used for drying nitrocellulose, sugars, starches, animal or vegetable tissues, and for dehydrating histological specimens. It is used in cosmetics and the cheaper varieties of perfume and culinary

ALCOHOL BUTYLICUM.—*n*-Butyl alcohol or butanol, $\text{CH}_3(\text{CH}_2)_3\text{OH}$, may be prepared by fermentation processes from maize flour, or synthetically from acetaldehyde, or by the catalytic hydrogenation of water-gas or coal-gas. It occurs as a colourless liquid, having a specific gravity of about 0.814 to 0.816 and a boiling-range of 113° to 119°. It is used in the manufacture of butyl acetate and as a solvent in the varnish and lacquer industries.

ALCOHOL METHYLICUM

(Alcoh. Methyl.)

Methyl Alcohol

Synonyms—Methanol; Methyl Alcohol (acetone-free).

Methyl alcohol, CH_3OH , may be obtained by the destructive distillation of wood or by the catalytic hydrogenation of water-gas and subsequent purification of the product. It occurs as a colourless liquid with an alcoholic odour, and is also known in commerce as Alcohol Methyl Puriss. (acetone-free). When treated with oxidising agents, such as acid solution of potassium permanganate, it yields formaldehyde and formic acid, and this reaction forms the basis of the usual test for methyl alcohol in ethyl alcohol.

Commercial wood spirit, wood naphtha, or pyroxylic spirit, is a clear, yellowish, inflammable liquid consisting of methyl alcohol (60 to 90 per cent.), together with acetone, aldehyde, water and other substances.

Wood spirit for use in denaturing alcohol is required to contain not less than 72 per cent. v/v of methyl alcohol, not more than 12 grammes per 100 millilitres of acetone, aldehyde and higher ketones, estimated as acetone, and not more than 3 grammes per 100 millilitres of esters, calculated as methyl acetate; it must also comply with certain limits for unsaturated compounds and acidity.

Miscible with water and organic solvents.

Standard.—Methyl alcohol has a specific gravity not higher than 0.799. Residue on evaporation, not more than 0.05 per cent. To 5 millilitres add 50 millilitres of sodium hydroxide solution (1 in 10) and 25 millilitres of N/10 iodine and shake repeatedly; no turbidity or precipitate appears, and when heated at 60° to 70° for thirty minutes, no odour of iodoform develops (limit of ethyl alcohol). To 5 millilitres add 2 millilitres of N/1 sodium hydroxide and 0.2 millilitre of a 2 per cent. aqueous solution of sodium nitroprusside; on slightly acidifying with acetic acid, no violet colouration is produced within one minute (limit of acetone). The colour of a mixture of 50 millilitres of the alcohol and 2 millilitres of a 0.02 per cent. solution of potassium permanganate maintained at 15° to 16° is not discharged within ten minutes (limit of readily oxidisable substances). On shaking in the cold with an equal volume of sulphuric acid, not more than a faint yellow colouration is produced (limit of empyreumatic substances).

Action and Uses.—Methyl alcohol is more slowly oxidised in the body than ethyl alcohol so that its effects last longer; the oxidation is also incomplete, formic acid and formaldehyde being formed. It is never given internally; one fluid drachm has caused permanent blindness and one fluid ounce has proved fatal. It has been used in so-called "hygienic" lamps designed for slow combustion by means of a cone of platinum black, formaldehyde being produced. It is largely employed as a solvent in the arts and sciences. Methyl alcohol is used as a solvent in the preparation of Leishman's stain for blood, preparatory to microscopical examination. In cases of **poisoning** by methyl alcohol the stomach should be evacuated by the stomach pump or by apomorphine given hypodermically. This should be followed by gastric lavage with sodium bicarbonate solution, and the administration of strong coffee, brandy, or strychnine.

ALETRIS

(Aletr.)

Aletris

Synonyms—Ague Root; Colic Root; Star Grass; Unicorn Root.

Aletris consists of the dried rhizome and roots of *Aletris farinosa* Linn. (Fam. Liliaceæ), a small perennial herb growing throughout the Eastern United States of America. It is collected after the plant has flowered.

The rhizome is short, horizontal, nearly cylindrical, from 1 to 6 centimetres in length and from 3 to 9 millimetres in thickness. The upper surface shows circular stem-scars and is covered with the papery fibrous bases of radical leaves, the upper parts of which have been cut away. The under surface bears numerous short, tough, wiry rootlets, some of which are devoid of the outer layers, or scars where rootlets have been broken off. The rhizome is brown externally and yellowish-white internally; the fracture is short and starchy in the cortex, uneven and lacunous in the centre. The odour is slight and resembles that of acetic acid; the taste at first is sweetish and afterwards soapy and bitter.

The diagnostic **microscopical** characters are the numerous small glandular trichomes, consisting of a unicellular stalk and a sub-spherical head; the cells of the cortex filled with starch grains, mostly simple, spherical or ellipsoidal, and from 3 to 15 microns (mostly 6 microns) in diameter; the occasional cortical cells filled with acicular raphides of calcium oxalate about 15 to 50 microns in length; the lacunar stele traversed in various directions by numerous concentric, vascular bundles having phloem in the centre and surrounded by rather thin-walled, lignified and pitted parenchyma.

No definite **constituents** have been isolated. It yields to alcohol (45 per cent.) from 9 to 15 per cent. of extractive.

Standard.—Aletris contains not more than 5 per cent. of foreign organic matter. Acid-insoluble ash, not more than 10 per cent.

Action and Uses.—Aletris is used in the form of elixir and liquid extract as a so-called “uterine tonic.”

Preparations

Elixir Aletridis, B.P.C.—(Elix. Aletr.)—Elixir of Aletris. Liquid extract of aletris, 1 in 4, with liquid extract of liquorice, simple elixir and distilled water. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Extractum Aletridis Liquidum, B.P.C.—(Ext. Aletr. Liq.)—Liquid Extract of Aletris. 1 in 1. Dose. 0.3 to 1 millilitre (5 to 15 minims).

ALLANTOINUM

(Allant.)

Allantoin

Allantoin is a diureide of glyoxylic acid. It is present in the allantoin, in comfrey root, and in the young shoots of the plane and maple, and may be prepared by the oxidation of uric acid with alkaline potassium permanganate solution. It occurs in colourless, glistening prisms, melting at about 235°. Oxidising agents convert it into allanturic acid, $\text{C}_3\text{H}_4\text{O}_2\text{N}_2$. The solution in sodium hydroxide evolves ammonia when heated, with simultaneous production of urea.

Soluble in water (1 in 130) and alcohol.

Action and Uses.—Allantoin has been used as a cell proliferant. Experiments on plants seem to show that it exerts a perceptibly stimulating action on growth. It may replace the decoction of comfrey root in the treatment of gastric ulcer. Proof as to its value in clinical medicine is still lacking. Allantoin has no antiseptic properties; it has been applied locally to sluggish wounds, sores, and abscesses to promote the formation of epithelial tissue.

Dose.—0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains).

ALLIUM

(*Allium*)

Garlic

Garlic is the fresh compound bulb of *Allium sativum* Linn. (Fam. Liliacæ). It is a native of Southern Europe, but is widely cultivated. Garlic may be kept in good condition for about six months after harvesting if **stored** in a cool, dry place and exposed to the air.

The compound bulb is subglobular, greyish-white, 4 to 6 centimetres in diameter, and consists of from 8 to 20 cloves, the whole of which are surrounded by from 3 to 5 whitish, papery, membranous scales, formed from the leaf-bases of the previous year's bulb and terminating in a thick, papery outgrowth. The cloves are attached to a flattened, circular, woody axis from which numerous thin, wiry roots arise on the under side and which bears upon the upper surface short, sub-cylindrical outgrowths, each of which forms the axis of a clove. Each clove is ovoid, appearing from 3- to 4-sided when cut transversely; the cut surface shows that each is surrounded by two papery scale leaves, the outer one whitish and loose, the inner one pink and adherent, but easily separable from the solid portion of the clove. These enclose two whitish, fleshy scales, the inner one thinner and smaller than the outer. In the centre are one or two yellowish-green, conduplicate foliage leaves. Garlic has a slight alliaceous odour, which becomes very strong and disagreeable when the drug is bruised; the taste is strongly pungent, alliaceous and persistent.

Garlic **contains** about 0.1 to 0.3 per cent. of an optically inactive volatile oil of specific gravity 1.045 to 1.060, containing allylpropyl disulphide and diallyl disulphide. It also contains a glycoside, alliin, which is hydrolysed by an enzyme, allisin, with formation of lævulose and the volatile oil. Garlic yields, when strongly pressed, about one-fourth of its weight of a viscous juice.

Action and Uses.—Garlic has antiseptic, diaphoretic, diuretic and expectorant properties. Large doses, continued, are stated to cause an increase in blood pressure. The juice has been used in laryngeal tuberculosis, and poultices made from pulped garlic are stated to be

useful in accessible tuberculous lesions. The juice, diluted with four parts of water, has been used **externally** for treating suppurating wounds, and by inhalation for pulmonary tuberculosis. The fresh juice is extremely irritating when applied to broken surfaces. Garlic is **administered** as juice, syrup, or volatile oil, also in the form of infusion which is sometimes taken in milk. Cases have been reported where its use internally has proved fatal to children.

Dose.— 2 to 8 grammes ($\frac{1}{2}$ to 2 drachms), of the fresh bulb.

Preparations

Succus Allii, B.P.C.—(Succ. Allii)—Juice of Garlic. The juice expressed from fresh garlic, mixed with alcohol (90 per cent.) and distilled water. **Dose.**— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Syrupus Allii, B.P.C.—(Syr. Allii)—Syrup of Garlic. Juice of garlic, about 18 per cent. v/v, with sucrose, dilute acetic acid and distilled water. **Dose.**— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

ALLOBARBITONUM

(Allobarbiton.)

Allobarbitone

Synonyms—Diallylbarbituric Acid; Diallylmalonylurea.

Allobarbitone is 5:5-diallylbarbituric acid and may be prepared by the condensation of the ethyl ester of diallylmalonic acid with urea. It occurs as a white, crystalline powder which is odourless and has a slightly bitter taste. The saturated aqueous solution is acid to litmus. When fused with caustic alkali, or when boiled with a strong solution, it gives off ammonia. When 0.1 gramme is dissolved in 1 millilitre of sulphuric acid, the solution is yellow, the colour changing slowly to a dark red. A saturated solution in water decolourises bromine water and potassium permanganate when either reagent is added drop by drop.

Slightly **soluble** in water; soluble in alcohol and ether; readily soluble in solutions of alkali hydroxides and carbonates.

Standard.—Allobarbitone melts between 171° and 172°. Ash, not more than 0.1 per cent.

Action and Uses.—Allobarbitone is a reasonably safe and reliable hypnotic. Its hypnotic action is similar to that of barbitone in that its administration is followed by quietness and sleep, but it is more readily absorbed. Idiosyncrasy to allobarbitone may be shown, a skin rash with fever being one of the common manifestations. Overdosage, often the result of cumulative action, may produce coma, with the attendant liability to respiratory complications. Allobarbitone is **administered** in tablets or cachets swallowed with a draught of hot liquid, and is sometimes given by subcutaneous injection. In cases of **poisoning**

by allobarbitone, the procedure described under *Barbitonum* should be followed.

Dose.—0.03 to 0.18 gramme ($\frac{1}{2}$ to 3 grains).

ALLYLIS SULPHIDUM

(Allyl. Sulphid.)

Allyl Sulphide

$C_6H_{10}S = 114.1$

Allyl sulphide, $(C_3H_5)_2S$, may be prepared by heating allyl iodide with potassium sulphide in alcoholic solution. It is a colourless or pale yellow oil, with an unpleasant odour resembling that of garlic. It yields a crystalline precipitate with alcoholic solution of mercuric chloride or of platinic chloride. Allyl sulphide boils at about 138° , and has a specific gravity of 0.890 to 0.900.

Slightly **soluble** in water; soluble in alcohol and ether.

Action and Uses.—Allyl sulphide, when injected intravenously in large doses, acts chiefly on the respiratory centre in the medulla, paralysing it rapidly; it acts to a lesser degree on the vasomotor centre. When given orally it is excreted by the lungs and skin. One half-minim of allyl sulphide per kilogramme of body-weight may be taken as being the lethal dose; death results from asphyxia owing to paralysis of the respiratory centre. Allyl sulphide is regarded as a powerful germicide, and is used chiefly in the treatment of tuberculosis; for this purpose it is **administered**, diluted with oil, in capsules, or inhaled from an oro-nasal inhaler. Its use rapidly diminishes cough and expectoration. Allyl sulphide is also administered in chronic bronchitis and bronchiectasis; it was formerly recommended for use in cholera. It should not be given undiluted on account of its irritant properties. Local applications have been used in lupus and tuberculous abscesses; a subcutaneous injection of a solution in oil has also been recommended. In cases of **poisoning** by allyl sulphide, artificial respiration should be used.

Dose.—0.03 to 0.12 millilitre ($\frac{1}{2}$ to 2 minims).

ALOE

(Aloe)

Aloes

Aloes is the solid residue obtained by evaporating the liquid which drains from the leaves cut from various species of *Aloe* (Fam. Liliaceæ). The juice is concentrated by spontaneous evaporation or, more

generally, by boiling, until it solidifies on cooling; it is then poured into boxes or other suitable receptacles. Slow and moderate concentration of the juice tends to induce crystallisation of the aloin, thus causing the drug to appear opaque; such aloes is termed "livery" or "hepatic" and splinters of it exhibit minute crystals of aloin when examined under the microscope. If, on the other hand, the evaporation is carried out rapidly and taken as far as possible, the aloin does not crystallise and small fragments of the drug appear transparent; it is then termed "glassy," "vitreous," or "lucid" and does not exhibit crystals of aloin under the microscope.

Cape aloes occurs in dark brown or greenish-brown, glassy masses, thin fragments of which are transparent and exhibit a yellowish, reddish-brown, or greenish tinge; it breaks with a clean, glassy fracture and has a distinctive, somewhat acid odour. Curaçao aloes has a dark, chocolate-brown colour and occurs usually in opaque masses, which break with a dull, waxy, uniform and frequently conchoidal fracture; it has a characteristic penetrating odour; occasional specimens are vitreous. Socotrine aloes occurs in hard, dark brown or nearly black, opaque masses, with an uneven, porous fracture, and an unpleasant, cheesy odour. Zanzibar aloes is livery-brown and has a nearly smooth, slightly porous fracture; its odour is slight and not disagreeable. Aloes has a nauseous, bitter taste. The following chemical tests may be used to identify aloes and its varieties. Prepare a 1 per cent. w/v solution by boiling aloes with water until nearly dissolved, adding diatomite and filtering until clear. Add 0.2 gramme of borax to 5 millilitres of the filtrate and dissolve by boiling; a few drops of the resulting solution give a green fluorescence when added to water. Another portion of the filtered aqueous solution gives a copious, pale yellow precipitate when mixed with an equal volume of freshly prepared bromine solution. Mix 5 millilitres of the filtrate with 2 millilitres of nitric acid; that prepared from Cape aloes gives a yellowish-brown colour, passing rapidly to a vivid green; with Curaçao aloes, the colour is a deep brownish-red; with Socotrine aloes, a pale brownish-yellow; and with Zanzibar aloes, a yellowish-brown. The Cape and Curaçao varieties are almost entirely **soluble** in alcohol (60 per cent.).

Aloes **contains** the pale yellow, crystalline glycoside, barbaloin. In Curaçao aloes this is accompanied by isobarbaloin, but little or none of the latter is found in the other varieties. There is also present an amorphous β -barbaloin which can be produced by heating barbaloin for about three hours at 160° to 165°; these substances are water-soluble. Other constituents are resin, aloë-emodin and water-soluble substances of which nothing definite is known; aloë-emodin is a hydrolytic product of barbaloin. The resin of Cape aloes and probably of Zanzibar and of Socotrine aloes consists of capaloresinotannol combined with *p*-cumaric acid; the resin of Curaçao aloes contains also barbaloresinotannol combined with cinnamic acid. Cape aloes may yield up to nearly 10 per cent. of crystallisable aloins; good Curaçao aloes may yield up to 30 per cent.; Socotrine and Zanzibar aloes yield rather less.

Varieties.—Four varieties of aloes are official in the British Pharmacopœia; these are known in commerce as Cape, Curaçao, Socotrine and Zanzibar aloes. Cape aloes is prepared in Cape Colony from *Aloe ferox* Miller. Curaçao aloes is obtained from *A. vera* Linn. var. *officinalis* (Forsk.) Baker on the Dutch Islands of Curaçao, Aruba and Bonaire; it was formerly produced on the island of Barbados and is still frequently, but improperly, called Barbados aloes. Socotrine aloes is prepared to a certain extent on the island of Socotra, but probably more largely on the African and possibly also on the Arabian mainland, from the leaves of *Aloe Perryi* Baker; it is imported usually in kegs in a pasty condition and subsequent drying is necessary. Zanzibar aloes, which is generally regarded as a variety of Socotrine, is usually imported in skins or in masses covered with leaves.

Substitutes.—Other kinds of aloes are known in commerce. Natal aloes, believed to be derived from *A. candelabrum* Berger, is rarely imported; it resembles Cape aloes in odour, but is opaque, and when the powder is mixed with sulphuric acid and the vapour of nitric acid blown over it, a deep blue colouration is produced. "Mocha" aloes is occasionally imported from Bombay; it is a black, brittle, glossy aloes with a strong odour, and is of inferior quality. Jaffarabad aloes is also nearly black, but does not enter English commerce.

Standard, B.P.—Aloes loses, when dried at 100°, not more than 10 per cent. of its weight. Ash, not more than 5 per cent.

Aloes, in powder (Pulvis Aloes : Pulv. Aloes), contains the constituents and possesses the properties of Aloe, and complies with the standard for the unground drug.

Action and Uses.—Aloes is used as a cathartic. A dose of from 2 to 3 grains takes from eight to twelve hours to produce an effect; this may be due to the fact that aloin is slowly converted, in the bowel, into an amorphous body which induces the local irritation; its action is therefore delayed, and is exerted on the large intestine. It is one of the most valuable drugs in the treatment of constipation. The pronounced action of aloes on the large intestine induces some pelvic congestion, and it is, therefore, employed as an emmenagogue in amenorrhœa, generally with iron. Aloes should not be used when there is intestinal irritation or catarrh. Its use is contra-indicated for pregnant or nursing women. Preparations of aloes are rarely prescribed alone; they require the addition of carminatives to moderate the tendency to griping. The compound preparations of aloes in use generally contain such correctives. Aloes in one form or another is a common domestic medicine, and is the basis of many proprietary pills.

Dose.—0·12 to 0·3 gramme (2 to 5 grains).

Preparations

Decoctum Aloes Compositum, B.P.C.—(Dec. Aloes Co.)—Compound Decoction of Aloes. Aloes, 1 per cent. w/v, with myrrh, potassium carbonate, extract of liquorice, compound tincture of cardamom and distilled water. When Decoctum Aloes Compositum is prescribed, either this preparation, or Decoctum Aloes Compositum (concentratum diluted with three times its volume of distilled water, may be dispensed. Dose.—15 to 60 millilitres ($\frac{1}{2}$ to 2 fluid ounces).

This decoction, prepared with extract of aloes instead of aloes, was included in the British Pharmacopœia, 1914.

Decoctum Aloes Compositum Concentratum, B.P.C.—(Dec. Aloes Co. Conc.)—Concentrated Compound Decoction of Aloes. A product closely resembling compound decoction of aloes is obtained by diluting one part of this preparation with three parts of distilled water. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Extractum Aloes, B.P.C.—(Ext. Aloes)—Extract of Aloes. A dry aqueous extract. Dose.—0.06 to 0.25 gramme (1 to 4 grains).

Pilula Aloes, B.P.—(Pil. Aloes)—Pill of Aloes. Aloes, about 58 per cent., with hard soap, oil of caraway and syrup of liquid glucose. Dose.—0.25 to 0.5 gramme (4 to 8 grains).

Pilula Aloes et Asafetidae, B.P.—(Pil. Aloes et Asafet.)—Pill of Aloes and Asafetida. Aloes and asafetida, of each about 30 per cent., with hard soap and syrup of liquid glucose. Dose.—0.25 to 0.5 gramme (4 to 8 grains).

Pilula Aloes et Ferri, B.P.—(Pil. Aloes et Ferr.)—Pill of Aloes and Iron. Exsiccated ferrous sulphate, about 10 per cent., and aloes about 20 per cent., with cinnamon, cardamom, ginger and syrup of liquid glucose. 0.5 gramme contains about 0.05 gramme of exsiccated ferrous sulphate corresponding to about 0.015 gramme of iron; 8 grains contains about $\frac{1}{4}$ grain of exsiccated ferrous sulphate corresponding to about $\frac{1}{4}$ grain of iron. Dose.—0.25 to 0.5 gramme (4 to 8 grains).

Pilula Aloes et Myrrhae, B.P.C.—(Pil. Aloes et Myrrh.)—Aloes and Myrrh Pills. *Syn.*—Pilulae Rufi; Rufus Pills. Each pill contains 2 grains of aloes and 1 grain of myrrh. Dose.—1 or 2 pills.

The mass with which these pills are made was included in the British Pharmacopoeia, 1914.

Pilula Aloes et Nucis Vomicae, B.P.C.—(Pil. Aloes et Nuc. Vom.)—Aloes and Nux Vomica Pills. Each pill contains 2 grains of aloes, $\frac{1}{4}$ grain of dry extract of nux vomica and $\frac{1}{8}$ grain of dry extract of belladonna. Dose.—1 pill.

Pilula Colchici et Aloes, B.P.C.—(Pil. Colch. et Aloes)—Colchicum and Aloes Pills. Each pill contains $\frac{1}{4}$ grain each of dry extract of colchicum, dry extract of hyoscyamus and aloes. Dose.—1 to 4 pills.

Pulvis Aloes et Canellae, B.P.C.—(Pulv. Aloes et Canell.)—Aloes and Canella Powder. *Syn.*—Hiera Picra. Aloes, 4 parts; canella, 1 part. Dose.—0.2 to 0.6 gramme (3 to 10 grains).

Tinctura Aloes, B.P.C.—(Tinct. Aloes)—Tincture of Aloes. Aloes, 1 in 40, and liquid extract of liquorice, about 1 in 6. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Tinctura Aloes Composita, B.P.C.—(Tinct. Aloes Co.)—Compound Tincture of Aloes. Aloes, about 1 in 30, and gentian, rhubarb and ginger, of each 1 in 200. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Tinctura Aloes et Myrrhae, B.P.C.—(Tinct. Aloes et Myrrh.)—Tincture of Aloes and Myrrh. *Syn.*—Elixir Proprietatis. Aloes, 1 in 10, and saffron, in tincture of myrrh. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Tinctura Antiperiodica, B.P.C.—(Tinct. Antiperiod.)—Antiperiodic Tincture. *Syn.*—Warburg's Tincture. Aloes, about 1 in 40, quinine sulphate, 1 in 50, with rhubarb, angelica fruit, elecampane, saffron, fennel, chalk, gentian, zedoary, cubeb, myrrh, agaric, opium, black pepper, cinnamon, ginger and camphor. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Vinum Aloes, B.P.C.—(Vin. Aloes)—Aloes Wine. Aloes, about 1 in 30, cardamom and ginger, macerated in sherry-type wine. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

ALOINUM

(Aloin.)

Aloin

Aloin is a mixture of crystalline principles obtained from aloes; it is obtained chiefly from Curaçao aloes, but may be obtained also from other varieties. It may be extracted from aloes by means of boiling acidified water, the filtered solution being evaporated and allowed to crystallise. When obtained from Curaçao aloes it consists of the crystalline substances barbaloin and *isobarbaloin* in approximately equal proportions. Barbaloin, $C_{21}H_{20}O_9$, is a methylantraquinone derivative of glycosidal character yielding aloë-emodin (trihydroxy-methylantraquinone) and *d*-arabinose on hydrolysis; it is converted into amorphous β -barbaloin by heating at 160° to 165° for about three hours. *iso*Barbaloin is distinguished by yielding the cupraloin reaction. Aloin obtained from Socotrine or Zanzibar aloes consists chiefly of barbaloin, but also contains β -barbaloin; *isobarbaloin* is absent.

Aloin occurs as a pale yellow, microcrystalline powder which is odourless, or has a faint odour of aloes, and has an intensely bitter taste. It is stable in neutral or acid solutions but not in alkaline solutions. It dissolves readily in ammonium hydroxide solution, giving a liquid which is red, or yellow changing to red, and has a greenish-red fluorescence.

Almost entirely **soluble** in water (about 1 in 130), alcohol and acetone; almost insoluble in ether, chloroform and benzene. The proportion of matter insoluble in water varies greatly with the temperature of the water, and samples giving less than 1.5 per cent. at 25° may yield as much as from 7 to 10 per cent. at 15° .

• **Standard, B.P.**—Aloin yields, on ignition, not more than 0.5 per cent. of residue and contains not more than 1.5 per cent. of matter insoluble in water. The saturated aqueous solution is neutral or only faintly acid to litmus.

Action and Uses.—The action of aloin is the same as that of aloes, although it has the disadvantage of being more easily absorbed. It has sometimes produced signs of renal irritation during excretion in the urine. It is **administered** in the form of pills, tablets, or cachets, often with phenolphthalein, and is frequently combined with extract of nux vomica or strychnine, ferrous sulphate, myrrh, ipecacuanha and extract of belladonna.

Dose.—0.016 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

Preparations

Pilulæ Aloini Compositæ, B.P.C.—(Pil. Aloin. Co.)—Compound Aloin Pills.

Syn.—Andrew Clark's Liver Pills. Each pill contains $\frac{1}{2}$ grain each of aloin, dry extract of nux vomica, exsiccated ferrous sulphate, myrrh and hard soap, Dose.—1 pill.

Pilulæ Aloini et Podophyllini Compositæ, B.P.C.—(Pil. Aloin. et Podoph. Co.)—Compound Aloin and Podophyllin Pills. Each pill contains $\frac{1}{10}$ grain each of aloin and jalap resin, $\frac{1}{100}$ grain of oleoresin of capsicum, $\frac{1}{20}$ grain each of the dry extracts of nux vomica and hyoscyamus, and about $\frac{1}{2}$ grain of resin of podophyllum. Dose.—1 to 4 pills.

Pilulæ Aloini et Strychninæ Compositæ, B.P.C.—(Pil. Aloin. et Strych. Co.)—Compound Aloin and Strychnine Pills. Each pill contains $\frac{1}{2}$ grain of aloin, $\frac{1}{10}$ grain of strychnine, $\frac{1}{10}$ grain of dry extract of belladonna and $\frac{1}{10}$ grain of powdered ipecacuanha. Dose.—1 or 2 pills.

Pilulæ Ferri Carbonatis Compositæ, B.P.C.—(Pil. Ferr. Carb. Co.)—Compound Iron Carbonate Pills. *Syn.*—Blaud's Pill with Aloin and Cascara. Each pill contains $\frac{1}{10}$ grain of aloin, $\frac{1}{2}$ grain of dry extract of cascara sagrada and 5 grains of pill of iron carbonate. Dose.—1 to 3 pills.

Pilulæ Phenolphthaleini Compositæ, B.P.C.—(Pil. Phenolphthal. Co.)—Compound Phenolphthalein Pills. *Syn.*—Pilulæ Phenolaini. Each pill contains $\frac{1}{2}$ grain of aloin, $\frac{1}{2}$ grain of phenolphthalein, $\frac{1}{10}$ grain of strychnine, $\frac{1}{10}$ grain of dry extract of belladonna and $\frac{1}{5}$ grain of powdered ipecacuanha. Dose.—1 or 2 pills.

Tabellæ Aloini Compositæ, B.P.C.—(Tab. Aloin. Co.)—Compound Aloin Tablets. Each tablet contains $\frac{1}{2}$ grain of aloin, $\frac{1}{2}$ grain of powdered ipecacuanha and $\frac{1}{2}$ grain of dry extract of nux vomica. Dose.—1 or 2 tablets.

Tabellæ Ferri Carbonatis et Aloini, B.P.C.—(Tab. Ferr. Carb. et Aloin.)—Tablets of Iron Carbonate and Aloin. *Syn.*—Blaud's Tablets with Aloin. Each tablet is approximately equivalent to 5 grains of pill of iron carbonate and contains also $\frac{1}{10}$ grain of aloin. Dose.—1 to 6 tablets.

ALSTONIA

(Alston.)

Alstonia

Synonyms—Australian Fever Bark; Alstoniæ Cortex; Dita Bark.

Alstonia is the dried bark of *Alstonia scholaris* R. Br. (Fam. Apocynaceæ), a tree growing in India, Burma and the Philippine Islands, known as dita bark, and of *A. constricta* F. Muell., which grows in Australia, known as Australian fever bark.

The bark of *A. scholaris* occurs in channelled or, occasionally, quilled pieces, up to about 3 to 4 millimetres thick, from the branches, and cut or broken, irregular, curved or flat pieces, up to about 7 millimetres thick, from the stem. Externally, the younger bark is dark grey to brownish and the older bark is very rough, uneven and much fissured, both transversely and longitudinally; both are marked by numerous rounded or transversely elongated, grey to whitish-brown lenticels. Internally, it is brownish-buff to dark greyish-brown, somewhat striated and indented. The fracture is short and the smoothed transverse surface shows a narrow, inner portion traversed by numerous, fine, medullary rays and a spongy outer portion of varying extent. It is odourless, and the taste persistently bitter. The bark of *A. constricta* occurs in quills and curved pieces, often of considerable size. The

outer surface is brown or yellowish-brown, strongly rugose, with large, deeply fissured reticulations; internally, it is cinnamon-brown and coarsely striated. The transverse section exhibits an abundant dark brown periderm, within which is a yellowish-brown layer, the secondary phloem, which contains abundant fibres in tangentially arranged groups. The fracture is short and granular in the outer layers and fibrous in the inner. *Alstonia* has a very bitter taste and yields a yellowish infusion having a well-marked blue fluorescence.

The bark of *A. scholaris* contains the alkaloids, ditamine, echitenine, echitamidene and echitamine. Echitamine (ditaine), $C_{22}H_{28}O_4N_2 \cdot H_2O$, the most important of these alkaloids, forms crystalline salts and has also been obtained from a Java species, *A. spectabilis* R. Br., and two West African plants, *A. congensis* Engl. and *A. Gilletii* De Wild. Echitamidene, $C_{20}H_{26}O_3N_2 \cdot H_2O$, melting-point, 135° , is crystalline and also occurs in *A. congensis*. Ditamine, $C_{16}H_{19}O_2N$, melting-point, 75° , and echitenine, $C_{20}H_{27}O_4N$, melting-point, above 120° , are amorphous, bitter powders about which little is known. The following constituents have also been extracted from the bark:—Echicerin, a crystalline non-nitrogenous body; echicaoutchin, an amorphous substance resembling caoutchouc; echitin and echitein, both of which are crystalline, and echiretin, which is amorphous; all these constituents appear to be devoid of marked therapeutic properties. The bark of *A. constricta* contains the alkaloids, alstonine (chlorogenine), $C_{21}H_{20}O_3N_2$, and porphyrine. It also contains porphyrosine and alstonidine, about which little definite is known. Porphyrine is amorphous and colourless, and shows a blue fluorescence in acid solution.

Action and Uses.—*Alstonia* is used in India and the Eastern Colonies as a tonic in malarial conditions and as a remedy for chronic diarrhœa. Its value in malaria cannot be compared with that of cinchona bark, although it produces no bad effects such as cinchonism. For **administration**, the infusion (Infusum *Alstoniæ*, 1 in 20; dose, $\frac{1}{2}$ to 1 fluid ounce) and the tincture (Tinctura *Alstoniæ*, 1 in 8; dose, $\frac{1}{2}$ to 1 fluid drachm) may be employed.

ALTHÆA

(Alth.)

Althæa

Synonyms—Guimauve; Marshmallow; Marshmallow Root.

Althæa is the dried, peeled root of *Althæa officinalis* Linn. (Fam. Malvaceæ), a perennial plant widely distributed in Central and Southern Europe and cultivated in Belgium, France and Germany. The roots are collected in the autumn from plants not less than two years old, trimmed and scraped to remove the cork, and finally dried. They are sometimes split longitudinally or cut into transverse slices.

The root is yellowish-white in colour, straight and tapering, from 10

to 30 centimetres long and 10 to 20 millimetres in diameter, bearing deep and broad longitudinal furrows. The surface is softly fibrous and bears the brownish scars of lateral rootlets. The fracture is short, fibrous in the bark and granular in the wood; the fractured surface is whitish and starchy. The transverse section exhibits a moderately thick bark, separated from the wood by a greyish cambium line. The odour is faint and the taste mucilaginous.

The diagnostic **microscopical** features are the abundant bast fibres, which are unligified except for the middle lamella and occur in groups of 3 to 25; the numerous starch grains, mostly simple and ovoid in shape, measuring about 4 to 25 microns in diameter; occasional cluster-crystals of calcium oxalate; numerous mucilage cells which stain red with solution of ruthenium red.

Althæa contains from 25 to 35 per cent. of mucilage, which consists of glucosan and xylan. It also contains about 1·7 per cent. of an oil composed of the glycerides of palmitic and oleic acids, together with butyric acid and a phytosterol apparently identical with sitosterol. A hydroxy-acid of high molecular weight appears to be present and also a lecithin in which palmitic and oleic acids occur and the base of which is choline. The sugar is mainly sucrose.

Standard.—Althæa contains not more than 2 per cent. of foreign organic matter. Ash, not more than 8 per cent. Cold water extractive, not less than 20 per cent.

Althæa, in powder (*Pulvis Althææ*: *Pulv. Alth.*), contains the constituents and possesses the diagnostic microscopical characters of Althæa, and complies with the limits for ash and cold water extractive of the unground drug.

Action and Uses.—Althæa is demulcent and emollient. Taken internally it is a popular remedy for catarrhs and bronchitis. It may be given in the form of syrup. *Pâte de Guimauve* pastilles, which contain althæa flavoured with oil of neroli, are a useful and pleasant demulcent. The powdered root is used as an excipient for pills which require some inert, absorbent substance. Althæa has been applied to inflamed tissues as a fomentation (1 part of powdered root to 5 parts of water), the macerated drug being used as a poultice.

ALTHÆÆ FOLIUM.—Althæa, or marshmallow, leaves are greyish-green, broadly ovate, or nearly cordate, somewhat 5-lobed, with unequal triangular teeth, and covered with a velvety felt of stellate hairs. They have a mucilaginous taste and are almost odourless. The leaf is used in the preparation of an ointment which has been recommended for its soothing and emollient effects in a variety of skin diseases. A factitious ointment is often sold which consists of a mild resin ointment.

Preparation

Syrupus Althææ, B.P.C.—(*Syr. Alth.*)—Syrup of Althæa. *Syn.*—Syrup of Marshmallow. A solution of sucrose in the liquid obtained by macerating althæa in distilled water, preserved with chloroform. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

ALUMEN**(Alum.)****Alum***Synonyms*—Alumen Purificatum; Purified Alum.

Alum is either potassium aluminium sulphate, potash alum, ($\text{KAl}(\text{SO}_4)_2, 12\text{H}_2\text{O} = 474.4$) or ammonium aluminium sulphate, ammonia alum, ($\text{NH}_4\text{Al}(\text{SO}_4)_2, 12\text{H}_2\text{O} = 453.3$) and may be prepared by crystallising solutions containing aluminium sulphate and potassium or ammonium sulphate respectively. It occurs in colourless, transparent, octahedral crystals, or as a white powder, with a sweet and very astringent taste. When heated, alum at first dissolves in its water of crystallisation, and becomes anhydrous at about 200° . Roche alum was originally a native alum, but is now prepared artificially by colouring crystals of alum with red bole.

Soluble in water (potash alum, 1 in 10; ammonia alum, 1 in 8), boiling water (3 in 1), and glycerin (1 in 3); insoluble in alcohol.

Standard, B.P.—Potash alum and ammonia alum contain not less than 99.5 per cent. of $\text{KAl}(\text{SO}_4)_2, 12\text{H}_2\text{O}$ and of $\text{NH}_4\text{Al}(\text{SO}_4)_2, 12\text{H}_2\text{O}$, respectively. Arsenic limit, 5 parts per million. They comply also with tests for absence of copper and of zinc and with a limit test for iron. Potash alum complies with a tes. for the absence of ammonium salts, and ammonia alum complies with a limit test for alkali salts.

Action and Uses.—When taken internally the salts of aluminium are very slowly absorbed owing to their property of precipitating proteins. In small doses alum exerts an astringent action on the alimentary canal, more particularly the stomach; in larger doses it induces vomiting, and a strong solution may produce inflammation of the bowel and the stomach. Alum is not much employed internally, although it has been administered in the treatment of lead colic, and as an emetic in capillary bronchitis, spasmodic croup, food poisoning and narcotic poisoning. It is contra-indicated in corrosive poisoning and acute inflammation of the alimentary tract.

The astringency of salts of aluminium is due to their action in coagulating albumin. They coagulate protein on the surface of mucous membranes or on wounded surfaces. Alum is therefore used in solution as a local astringent in such conditions as stomatitis (about 1 per cent.), pharyngitis (about 4 per cent., applied by means of a spray), leucorrhœa (about 0.5 per cent.), gonorrhœa and gleet (about 0.5 per cent.) and in skin diseases (about 1 per cent.). Solutions containing from 0.5 to 2 per cent. are used in the treatment of purulent ophthalmia. As a gargle or spray for a relaxed throat, alum is used in combination with tincture of myrrh or acid infusion of roses. As an application to the mouth and throat for use in ulcerated conditions, pharyngitis, etc., glycerin of alum may be employed either as a paint or, diluted with eight parts of water or of acid infusion of roses, as a gargle or spray solution.

Alum is used externally in the form of a lotion, as a styptic to bleeding points, especially after tooth extraction, and for the relief and prevention of bed-sores. A strong solution hardens the epidermis and is a useful application for soft corns and ingrowing toe-nails. Localised hyperhidrosis may sometimes be relieved by bathing with a hot 2 per cent. solution of alum. For use as a foot powder 15 parts of alum may be mixed with 85 parts of purified talc. It is **incompatible** with alkalis and tannic acid.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

Preparations

Collyrium Aluminis, B.P.C.—(Collyr. Alum.)—Alum Eye Lotion. Alum, 1 in 100, in distilled water.

Gargarisma Aluminis, B.P.C.—(Garg. Alum.)—Alum Gargle. Glycerin of alum, 1 in 8, with acid infusion of roses.

Glycerinum Aluminis, B.P.—(Glycer. Alum.)—Glycerin of Alum. Potash alum, in crystals, 13 per cent. w/w, dissolved in water and glycerin. **Dose.**—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

ALUMEN CHROMICUM

(Alum. Chrom.)

Chrome Alum

Chrome alum, or chromium potassium sulphate, may be prepared by the combination of potassium sulphate with chromium sulphate, or by passing sulphur dioxide into a solution of potassium dichromate in the presence of sulphuric acid. It occurs in large, violet, octahedral crystals. The solution in water is violet, but on heating at 60° to 80° the colour changes to green; on standing for some weeks the solution returns to its original colour.

Soluble in water (1 in 7); insoluble in alcohol.

Uses.—Chrome alum is not used in medicine, but is employed largely in tanning and as a mordant in dyeing, and also for the hardening of the gelatin of photographic plates and films.

ALUMEN EXSICCATUM

(Alum. Exsic.)

Exsiccated Alum

Synonyms—Alumen Ustum; Burnt Alum.

Exsiccated alum is potash alum, $\text{KAl}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$, deprived of

its water of crystallisation by heating until it liquefies, then heating at a higher temperature until water vapour ceases to be given off and the salt has lost from 45 to 46 per cent. of its weight. When, on drying, the alum is subjected to a temperature above 200° , some sulphuric acid is expelled and the product is not completely soluble in water owing to the formation of insoluble aluminium oxysulphate. It occurs as a white powder, or in masses.

Soluble in 20 parts of water, slowly and completely.

Standard.—Exsiccated alum, determined by the method of the British Pharmacopœia for Alumen, contains not less than 99.5 per cent. of $KAl(SO_4)_2$, calculated on the substance dried at 200° ; 1 gramme of residue is equivalent to 5.066 grammes of $KAl(SO_4)_2$. Loss on drying at 200° , not more than 10 per cent. In other respects it complies with the requirements for Alumen (potash alum) when one half the quantity is taken for each test.

Action and Uses.—Exsiccated alum is a very powerful astringent. It is useful as a dressing for old ulcers and sores, and as an astringent for swollen gums. In consequence of its power of absorbing water, it is serviceable as a mild caustic. Exsiccated alum is used by taxidermists for preserving purposes, the powder being well rubbed into the skins.

ALUMEN FERRICUM

(Alum. Ferr.)

Iron Alum

Iron alum is ferric ammonium sulphate, and may be prepared by adding ammonium sulphate to a boiling solution of ferric sulphate and crystallising, or by electrolysis of an acidified solution of ferrous and ammonium sulphates. It occurs in octahedral crystals of a pale violet colour, with an acid, astringent taste, and effloresces on exposure to air. When strongly heated the crystals fuse, losing water of crystallisation and finally leaving a pale brown residue. The aqueous solution reddens blue litmus and, if dilute, rapidly becomes turbid, although when concentrated it remains clear for several months.

Soluble in water (1 in 3); insoluble in alcohol.

Action and Uses.—The properties of iron alum are essentially those of ferric sulphate. It is employed as an astringent gargle (1 in 50), as a paint for the throat (1 in 12), and **internally** to arrest hæmorrhage. It is used also as a reagent.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

ALUMINII CHLORIDUM

(Alumin. Chlor.)

Aluminium Chloride

Aluminium chloride may be prepared by the action of barium chloride on a solution of aluminium sulphate and subsequent crystallisation from the filtrate. It occurs in the form of nearly white, deliquescent crystals or as a granular, crystalline powder. It cannot be dehydrated without suffering decomposition; the anhydrous variety is obtained by passing chlorine over the metal. Aluminium chloride should be **stored** in closely stoppered bottles.

Very **soluble** in water (2 in 1), alcohol (1 in 4) and glycerin.

Standard.—Aluminium chloride, determined by the method of the British Pharmacopœia for Alumen, contains not less than 95 per cent. of $\text{AlCl}_3, 6\text{H}_2\text{O}$; 1 gramme of residue is equivalent to 4.737 grammes of $\text{AlCl}_3, 6\text{H}_2\text{O}$. 0.1 gramme complies with the limit test for iron.

Action and Uses.—Aluminium chloride has been given internally in locomotor ataxy and is said to relieve the pains. For internal use, it should be administered in the form of a mixture. Pills are occasionally prescribed, but on account of the deliquescent nature of the salt they are difficult to prepare and also to preserve; they are best massed with Canada balsam and powdered althæa. Aluminium chloride in solution is antiseptic and astringent, and is used in the form of gargle (1 in 500), spray (1 in 300), or pigment (1 in 100).

Dose.—0.12 to 0.25 gramme (2 to 4 grains).

ALUMINII HYDROXIDUM

(Alumin. Hydrox.)

Aluminium Hydroxide

Aluminium hydroxide may be prepared by the interaction of alum and sodium carbonate in solution. The precipitate is washed, dried at a temperature not exceeding 40°, and reduced to a fine powder. It occurs as a white, light, amorphous powder, which is odourless and tasteless.

Insoluble in water, soluble in solutions of sodium and potassium hydroxides.

Standard.—Aluminium hydroxide loses, on heating to redness, not more than 34 per cent. of its weight. Arsenic limit, 20 parts per million. Boil 1 gramme with 20 millilitres of water and filter; on evaporating the filtrate and gently igniting, the residue weighs not more than 0.02

gramme (limit of alkali salts). 1 gramme with 2·5 millilitres of hydrochloric acid complies with the limit test for sulphates.

Action and Uses.—Aluminium hydroxide is employed as a protective agent for the gastric mucous membrane in cases of gastric or duodenal ulcer associated with hyperacidity. **Externally** it is used in the form of a dusting powder, aqueous suspension, or ointment as a mild astringent and desiccant.

Dose.—0·3 to 0·6 gramme (5 to 10 grains).

ALUMINII ACETAS.—Aluminium acetate, $\text{Al}_2(\text{C}_2\text{H}_3\text{O}_2)_6$, may be prepared by dissolving freshly precipitated aluminium hydroxide in strong acetic acid, or by precipitating a solution of aluminium sulphate with lead acetate; it can be obtained as a soluble, gummy mass, but it is chiefly used in solution, in the form of *Liquor Aluminii Acetatis*, as an astringent in lotions and mouth-washes.

ALUMINII SUBACETAS.—Aluminium subacetate, $\text{Al}_2\text{O}_3 \cdot 4\text{C}_2\text{H}_3\text{O}_2 \cdot 4\text{H}_2\text{O}$, may be prepared by dissolving aluminium hydroxide in acetic acid, or by decomposing aluminium sulphate with lead acetate, and heating the solution. It is a basic salt, and occurs as a light, white powder, sparingly soluble in water.

ALUMINII ACETO-TARTRAS.—Aluminium aceto-tartrate may be prepared by dissolving freshly precipitated aluminium hydroxide in a mixture of acetic and tartaric acids. It occurs in colourless crystals or scales, or as a crystalline powder, soluble in water (1 in 2), but insoluble in alcohol and ether.

Preparation

Liquor Aluminii Acetatis, B.P.C.—(*Liq. Alumin. Acet.*)—Solution of Aluminium Acetate. *Syn.*—*Liquor Aluminii Aceticus* Burw's Solution. A solution containing a basic aluminium acetate equivalent to about 2·5 per cent. w/v of aluminium oxide.

ALUMINII SULPHAS

(*Alumin. Sulph.*)

Aluminium Sulphate

Aluminium sulphate may be prepared by dissolving freshly precipitated aluminium hydroxide in diluted sulphuric acid and allowing the solution to crystallise. It occurs as a white powder or in crystalline masses. Heated to 200° , it loses its water of crystallisation.

Soluble in water (1 in 1), the solution having an acid reaction; insoluble in alcohol.

Standard.—Aluminium sulphate, determined by the method of the British Pharmacopœia for *Alumen*, contains not less than 99 per cent. of $\text{Al}_2(\text{SO}_4)_3 \cdot 16\text{H}_2\text{O}$; 1 gramme of residue is equivalent to 6·184 grammes of $\text{Al}_2(\text{SO}_4)_3 \cdot 16\text{H}_2\text{O}$. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. On the addition of an equal volume of N/10 sodium thiosulphate to a filtered 10 per cent. solution of the salt, not more than a faint opalescence develops within five minutes (limit of free acid). 0·1 gramme complies with the limit test for iron.

Action and Uses.—Aluminium sulphate has the same medicinal properties as alum, but its astringent action is somewhat more pronounced. It is given **internally** as an astringent in the form of a mixture. A saturated solution is employed as a mild caustic for enlarged tonsils, nasal polypi, and in other conditions where a mild caustic is indicated. Solutions (5 to 10 per cent.) are used as local applications to ulcers, and to stop foul discharges from mucous surfaces. A 2 per cent. solution is used for removing wrinkles.

Dose.—0·12 to 0·3 gramme (2 to 5 grains).

AMIDOPYRINA

(Amidopyrin.)

Amidopyrine

Amidopyrine, or 4-dimethylamino-1-phenyl-2:3-dimethyl-5-pyrazolone, is dimethylaminophenazone. It may be prepared by the reduction of nitrosophenazone and treatment of the aminophenazone so obtained with methyl iodide. Amidopyrine occurs in small, colourless crystals, or as a white, crystalline powder, and is odourless and almost tasteless. The addition of ferric chloride solution to an aqueous solution of amidopyrine produces a bluish-violet colour, becoming violet-red on the addition of dilute sulphuric acid. Silver nitrate solution gives an intense violet colouration followed by a black precipitate of silver. A violet colour is also produced on adding a trace of sodium nitrite to a faintly acid solution of amidopyrine, the colour fading when the mixture is warmed. Potassium ferricyanide solution, followed by a few drops of ferric chloride solution, gives a dark bluish-green colour. These tests distinguish amidopyrine from phenazone and from acetanilide.

Soluble in water (about 1 in 18), alcohol (about 1 in 2), ether, chloroform and benzene.

Standard, B.P.—Amidopyrine melts at 107° to 109° . Ash, not more than 0·1 per cent. It complies also with a limit test for readily carbonisable substances.

Action and Uses.—Amidopyrine is analgesic and antipyretic, resembling phenazone in its action, but it is effective in smaller doses; its action is exerted somewhat more slowly, is of longer duration and it is stated to be without harmful effect on the heart, kidneys or blood. It has been recommended for use in pneumonia, erysipelas and the acute infectious fevers, such as typhoid fever. It is said to be almost specific in measles and, if given in the early stages, to be capable of aborting an attack. It has also been used largely in chronic tuberculosis, neuralgia, sciatica, migraine and dysmenorrhœa. Amidopyrine may be prescribed with barbituric acid derivatives for its

analgesic effect in the treatment of migraine and neuralgia. It is administered as powder, or in cachets, capsules, or tablets. It is **incompatible** with oxidising agents, nitrites, apomorphine and acacia.

Dose.—0·3 to 0·6 gramme (5 to 10 grains).

AMIDOPYRINÆ SALICYLAS.—Amidopyrine salicylate occurs as a white, crystalline powder. It may be administered in the form of tablets, each containing 0·3 gramme (5 grains), for the pain of neuralgia and rheumatism.

AMIDOPYRINÆ CAMPHORAS.—Amidopyrine camphorate has been used to diminish the sweats of phthisis. **Dose.**—0·3 to 0·6 gramme (5 to 10 grains).

Preparation

Tabellæ Barbitoni et Amidopyrinæ, B.P.C.—(Tab. Barbiton. et Amidopyrin.)—Tablets of Barbitone and Amidopyrine. Each tablet contains 2 grains of barbitone and 4 grains of amidopyrine. **Dose.**—1 tablet.

AMMONIACUM

(Ammoniac.)

Ammoniacum

Ammoniacum is a gum-resin obtained from the flowering and fruiting stem of *Dorema Ammoniacum* Don. (Fam. Umbelliferae) and possibly other species. The plants, which are widely distributed throughout Persia, extending into Southern Siberia, are visited by beetles; the stems are punctured and an exudation induced of the secretion contained in the schizogenous ducts of the cortex. The exudation, which dries on the stem in the form of tears, is collected.

The gum-resin is composed of separate, pale yellow tears or nodular masses, darkening with age and varying from 0·5 to 3·0 centimetres in diameter. It is brittle when cold, softening on warming, having a characteristic, but not a strong odour, and a bitter, acrid taste. The fractured surface is white or pale brown in colour. When the powdered drug is extracted with ether, the solution acquires a violet colour on the addition of a drop of ferric chloride solution and a small crystal of sodium carbonate.

Ammoniacum **contains** volatile oil (0·1 to 0·3 per cent.), resin (65 to 70 per cent.) and a gum resembling acacia. The resin consists of a resene (20 per cent.) associated with ammorestinotannol combined with salicylic acid. Traces of free salicylic acid are also present.

Substitutes.—A part of the exudation falls to the ground forming block or lump ammoniacum which consists of particles of gum-resin agglutinated together with a bluish, resinous substance, often being admixed with stones, fragments of the stem fruit and other debris. Moroccan ammoniacum, derived from *Ferula communis* Linn. var. *nodiflora* Linn., and the Cyrenian drug, from *Ferula marmarica* Aschers and Taub., are occasionally met with in commerce.

Standard.—Ammoniacum yields to alcohol (90 per cent.) not less

than 60 per cent. of extractive. Ash, not more than 7 per cent. An orange-red colouration is produced on adding solution of chlorinated soda to an emulsion of ammoniacum with water (distinction from the Moroccan drug). The solution obtained by boiling 0.2 gramme of the coarsely powdered gum-resin for a few minutes with 2 millilitres of hydrochloric acid and then diluting with an equal volume of water, does not exhibit a blue fluorescence when filtered and made alkaline with solution of ammonia (absence of asafetida and Moroccan ammoniacum).

Action and Uses.—Internally, ammoniacum facilitates expectoration and is of value in chronic bronchitis, especially in the aged, when the secretion is tough and viscid. It has a mild diuretic action. **Externally**, it acts as a slight irritant in virtue of the essential oil that it contains. Ammoniacum is a constituent of *Pilulæ Scillæ Compositæ* and *Pilulæ Ipecacuanhæ cum Scilla*.

Dose. 0.3 to 1 gramme (5 to 15 grains).

Preparation

Mistura Ammoniæ, B.P.C.—(Mist. Ammoniac.)—Ammoniacum Mixture. Each fluid ounce contains the aqueous extractive from about 13 grams of ammoniacum, with syrup of tolu and distilled water. Dose 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

This mixture was included in the British Pharmacopæia, 1914.

AMMONII ACETAS

(Ammon. Acet.)

Ammonium Acetate

Ammonium acetate, $\text{CH}_3\cdot\text{COONH}_4$, may be obtained by neutralising acetic acid with ammonia. It occurs in white crystals, or crystalline masses. Its solution in water is always acid to litmus.

Very **soluble** in water and alcohol.

Standard. Ammonium acetate, determined by the method of the British Pharmacopæia for *Liquor Ammonii Acetatis Fortis*, contains not less than 98 per cent. of $\text{C}_2\text{H}_3\text{O}_2(\text{NH}_4)$. Residue on gentle ignition, not more than 0.05 per cent. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. 0.5 gramme complies with the limit test for iron.

Action and Uses.—Ammonium acetate has the action of a typical saline that is easily absorbed. It is converted in the tissues of the body into urea, which exerts a diuretic action. As a mild expectorant, diuretic and diaphoretic, ammonium acetate is employed in febrile conditions, particularly those of childhood. It is **administered** as *Liquor Ammonii Acetatis Dilutus*.

Dose.—0.6 to 2 grammes (10 to 30 grains).

Preparations

Liquor Ammonii Acetatis Dilutus, B.P.—(Liq. Ammon. Acet. Dil.)—Dilute Solution of Ammonium Acetate. *Syn.*—Liquor Ammonii Acetatis; Solution of Ammonium Acetate; Mindererus Spirit. Strong solution of ammonium acetate, 1 in 8. It contains 7.2 per cent. w/v of $C_2H_3O_2(NH_4)$ (limits, 6.9 to 7.5) and has a reaction of between pH 7.0 and pH 8.0. Arsenic limit, 0.5 part per million. Lead limit, 0.6 part per million. It should be stored in bottles of lead-free glass. Dose.—8 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

Liquor Ammonii Acetatis Fortis, B.P.—(Liq. Ammon. Acet. Fort.)—Strong Solution of Ammonium Acetate. It is prepared by neutralising glacial acetic acid with ammonium carbonate and strong solution of ammonia, and contains 57.5 per cent. w/v of $C_2H_3O_2(NH_4)$ (limits, 55 to 60). Specific gravity, about 1.098. The reaction of a mixture of 1 millilitre with 10 millilitres of water is between pH 7.0 and pH 8.0. Arsenic limit, 4 parts per million. Lead limit, 5 parts per million. It should be stored in bottles of lead-free glass. Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

Mistura Ammonii Acetatis Composita, B.P.C.—(Mist. Ammon. Acet. Co.)—Compound Ammonium Acetate Mixture. *Syn.*—Mistura Diaphoretica. Each fluid ounce contains 20 grains of potassium citrate and 20 minims each of strong solution of ammonium acetate, spirit of nitrous ether and spirit of chloroform, with camphor water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

AMMONII BENZOAS

(Ammon. Benz.)

Ammonium Benzoate

Ammonium benzoate, $C_6H_5 \cdot COONH_4$, is formed by the combination of benzoic acid and ammonia. It occurs in white, scaly, almost odourless crystals. The salt usually has a feebly acid reaction due to loss of ammonia on keeping; such acid samples are less soluble than the freshly prepared salt. There are two varieties of the salt; they are made from natural and synthetic benzoic acids respectively.

Soluble in water (1 in 6), alcohol (1 in 30) and glycerin (1 in 8).

Standard.—Ammonium benzoate contains not less than 98 per cent. of $C_7H_5O_2(NH_4)$. Ash, not more than 0.1 per cent. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million.

Assay.—Dissolve 3 grammes, accurately weighed, in 25 millilitres of water in a separator, add 50 millilitres of N/2 sulphuric acid, and shake with 50 millilitres of ether; allow to separate, run off the lower layer and shake it with a further 25 millilitres of ether; run the aqueous layer into a titration flask, wash the mixed ethereal layers with 10 millilitres of water and add the washings to the contents of the flask; add 1 drop of methyl red indicator and titrate with N/2 sodium hydroxide to the orange end-point; each millilitre of N/2 sulphuric acid is equivalent to 0.06954 gramme $C_7H_5O_2(NH_4)$.

Action and Uses.—Ammonium benzoate, when given orally, increases slightly the acidity of the urine and is employed in catarrh

of the bladder and in phosphaturia. It is doubtful if it exerts any antiseptic action in the bladder, since, after ordinary doses of ammonium benzoate, the urine does not reach the degree of acidity necessary for the inhibition of bacterial growth. Ammonium benzoate is employed in chronic bronchitis in cases when the mucus is tenacious and difficult to remove by coughing.

Dose.—0.3 to 1 gramme (5 to 15 grains).

AMMONII BICARBONAS

(Ammon. Bicarb.)

Ammonium Bicarbonate

Ammonium bicarbonate may be prepared by passing carbon dioxide into a solution of ammonia or by treating ammonium carbonate with alcohol, when the carbamate dissolves and the bicarbonate remains undissolved. It occurs as a fine, white, crystalline powder or in white, rhomboid crystals, and is slightly hygroscopic. It has an odour of ammonia and a pungent taste, but is less caustic than the carbonate. It volatilises slowly at ordinary temperatures, but rapidly at 60°, giving ammonia, carbon dioxide and water.

Soluble in water (1 in 5½); insoluble in alcohol.

Standard, B.P.—Ammonium bicarbonate contains not less than 98 per cent. and not more than the equivalent of 102 per cent. of NH_4HCO_3 . Residue on volatilisation, not more than 0.01 per cent. Arsenic limit, 2 parts per million. Lead limit, 5 parts per million. It complies also with limit tests for tarry matter, chloride, sulphate and iron.

Action and Uses.—Ammonium bicarbonate has been used as a stimulant in place of ammonium carbonate, but it is rarely prescribed as such. It is suitable for use in effervescing draughts and to replace ammonium carbonate in the preparation of tablets and capsules.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

AMMONII BROMIDUM

(Ammon. Brom.)

Ammonium Bromide

Ammonium bromide may be prepared by the combination of hydrobromic acid with ammonia, or by the action of ammonium

carbonate on a solution of iron bromide. It occurs as colourless crystals or as a white, crystalline powder.

Soluble in water (2 in 3), alcohol (1 in 13).

Standard.—Ammonium bromide, determined by the method of the British Pharmacopœia for Potassii Bromidum, contains not less than 98 per cent. of NH_4Br , calculated on the salt dried at 100° ; each millilitre of N/10 silver nitrate is equivalent to 0.009796 gramme of NH_4Br . Loss on drying at 100° , not more than 1 per cent. Sulphated ash, not more than 0.1 per cent. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. Chloride, by the method for chloride in Potassii Bromidum, not more than 1.3 millilitres of N/10 silver nitrate. 2 grammes complies with the limit test for sulphates. 0.5 gramme complies with the limit test for iron. 1 gramme complies with the limit test for bromate in Potassii Bromidum.

Action and Uses.—The action of ammonium bromide is the same as that of potassium bromide, with the exception that it is absorbed a little more rapidly and is somewhat less depressing. As a general sedative, ammonium bromide is usually given in mixture form. For local application to the throat a linctus may be sipped, or lozenges or pastilles sucked slowly, but since the action of ammonium bromide is on the central nervous system, local applications have no special advantage. Ammonium bromide is **incompatible** with spirit of nitrous ether.

Dose.—0.3 to 2 grammes (5 to 30 grains).

Preparations

Ammonii Bromidum Effervescens, B.P.C.—(Ammon. Brom. Efferv.)—Effervescent Ammonium Bromide. About 1 in $12\frac{1}{2}$. Dose.—5 to 30 grammes (75 grains to 1 ounce).

Mistura Bromidi Composita, B.P.C.—(Mist. Brom. Co.)—Compound Mixture of Bromides. One fluid ounce contains 10 grains each of the bromides of ammonium, potassium and sodium, with tincture of nux vomica, solution of carmine, glycerin and chloroform water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

AMMONII CARBONAS

(Ammon. Carb.)

Ammonium Carbonate

Ammonium carbonate is a mixture of ammonium bicarbonate ($\text{NH}_4\text{HCO}_3 = 79.05$) and ammonium carbamate ($\text{NH}_4\text{NH}_2\text{CO}_2 = 78.06$) in varying proportions, and may be prepared by sublimation from a mixture of calcium carbonate and an ammonium salt. It occurs in hard, crystalline, translucent masses with a striated appearance; it has a strong odour of ammonia and a pungent, ammoniacal taste. On

exposure to the air it undergoes partial dissociation, with loss of ammonia and formation of a white efflorescence of ammonium bicarbonate. Ten parts of ammonium carbonate will neutralise approximately 13·3 parts of citric acid, or 14·3 parts of tartaric acid. It should be **stored** in well-closed containers.

Soluble in water (1 in 4) and glycerin (1 in 5); partly soluble in alcohol.

Standard, B.P.—Ammonium carbonate contains the equivalent of not less than 30 per cent. and not more than 32·5 per cent. of NH_3 . Residue on volatilisation at a temperature below a red heat, not more than 0·025 per cent. Arsenic limit, 2 parts per million. Lead limit, 5 parts per million. It complies also with limit tests for tarry matter, sulphate, chloride and iron.

Action and Uses.—The action of ammonium carbonate depends on the fact that it readily liberates ammonia. Ammonium carbonate mildly stimulates the gastric mucous membrane and is administered in certain forms of flatulent dyspepsia. It is a valuable expectorant and acts both reflexly on the medulla through irritation of the stomach and directly on the bronchial mucous membrane like any other saline. In large doses it causes vomiting. After absorption ammonium carbonate is changed to urea and causes some diuresis, but, unlike the carbonates of sodium and potassium, it does not render the blood more alkaline. Its employment in cases of sudden heart failure depends on its reflex effects from the respiratory and gastric mucous membranes.

It is generally **administered**, freely diluted, in mixtures, and is often given with tincture of ipecacuanha and infusion of senega. Single doses of 1·2 grammes (20 grains) in a draught of milk have been given in cases of acute pneumonia. Spiritus Ammoniae Aromaticus is employed as a stimulant and anti-spasmodic, and is especially useful with potassium or ammonium bromide in nervous headache and hysterical conditions. It is carminative and stimulates the heart and respiration reflexly, and is employed as a restorative in fainting.

Solutions of ammonium carbonate are used as applications to insect bites and wasp stings. It is used largely as “smelling salts” which, by irritating the nasal mucous membrane, act reflexly on the medullary centres. Inhalation of ammonia gas in this way produces constriction of the peripheral arterioles with a rise in blood pressure, stimulation of respiration, and a quicker and more forcible heart-beat. For this reason, it is employed in fainting and collapse and in any condition in which it is desirable to rouse the medullary centres. For dispensing purposes, freshly crushed ammonium carbonate or a solution (1 in 8) should be employed.

Dose.—0·3 to 0·6 gramme (5 to 10 grains).

Preparations

Liquor Ammoniae Aromaticus, B.P.C.—(Liq. Ammon. Aromat.)—Aromatic Solution of Ammonia. An aqueous solution of the same ammoniacal strength as aromatic spirit of ammonia. Dose—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

Mistura Ammoniae cum Senega, B.P.C.—(Mist. Ammon. c. Seneg.)—Ammonia Mixture with Senega. Each fluid ounce contains 4 grains of ammonium carbonate and 5 grains of ammonium chloride, with tincture of ipecacuanha and infusion of senega. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Spiritus Ammoniae Aromaticus, B.P.—(Sp. Ammon. Aromat.)—Aromatic Spirit of Ammonia. *Syn.*—Spirit of Sal Volatile. It is prepared from ammonium carbonate, strong solution of ammonia, oil of lemon, oil of nutmeg, alcohol (90 per cent.) and distilled water. It contains ammonia and ammonium carbonate together equivalent to not less than 2·1 per cent. and not more than 2·4 per cent. w/v of NH_3 , and not less than 1·265 per cent. and not more than 1·485 per cent. w/v of CO_2 . Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

AMMONII CHLORIDUM

(Ammon. Chlorid.)

Ammonium Chloride

Ammonium chloride may be obtained by neutralising a solution of ammonia with hydrochloric acid and purifying the product. It occurs as a white, granular, crystalline powder which is slightly hygroscopic. It is odourless and has a cooling, saline taste.

Soluble in water (about 1 in 3) and alcohol (about 1 in 60).

Standard, B.P.—Ammonium chloride contains not less than 99·5 per cent. of NH_4Cl , calculated on the substance dried in a vacuum desiccator over sulphuric acid. Loss on drying for twenty-four hours in a vacuum desiccator over sulphuric acid, not more than 1 per cent. Residue on volatilisation by gentle heat, not more than 0·1 per cent. Arsenic limit, 5 parts per million. Lead limit, 5 parts per million. It complies also with a test for the absence of barium, and with limit tests for sulphate and iron.

Action and Uses.—Ammonium chloride is rapidly absorbed from the stomach and small intestine, exerting the mildly expectorant, diaphoretic and diuretic actions of an ordinary saline. It increases the secretion of bronchial mucus, and is given to assist expectoration. Ammonium chloride, given by the mouth, increases the acidity of the urine. In painful conditions such as neuralgia and lumbago, in which there is an inflammatory exudate, ammonium chloride in doses of 2 grammes (30 grains) given three times daily may be beneficial. Administered hypodermically it causes pronounced stimulation of the central nervous system, but when given by the mouth, on account of its rapid excretion, this effect is wanting. In cases of lead poisoning, ammonium chloride, 1 to 2 grammes (15 to 30 grains) a day in divided doses, has been recommended to create a relative acidosis which hastens the elimination of the lead. A 1 per cent. solution of ammonium chloride may be used as a spray or gargle in acute pharyngitis and laryngitis; lozenges and pastilles containing 0·12 or 0·2 gramme (2 or 3 grains) of the salt are also used. A 2 per cent. solution in alcohol (50 per cent.) is useful as a lotion for contusions. Ammonium chloride is

used as an inhalation by placing solution of ammonia and hydrochloric acid separately in a suitable apparatus so that air drawn through it will pass first through the solution of ammonia and then through the hydrochloric acid, the resulting ammonium chloride being purified before inhalation by passing it through water or a moist sponge. Large doses of ammonium chloride may cause nausea, vomiting and thirst. Liquid extract of liquorice may be used to disguise its nauseous taste.

Dose.—0.3 to 4 grammes (5 to 60 grains).

Preparations

Pastilli Ammonii Chloridi Compositi, B.P.C.—(Pastill. Ammon. Chlorid. Co.)—Compound Ammonium Chloride Pastilles. Each pastille contains 2 grains of ammonium chloride and 2 minims of liquid extract of liquorice.

Trochisci Ammonii Chloridi Compositi, B.P.C.—(Troch. Ammon. Chlorid. Co.)—Compound Ammonium Chloride Lozenges. *Syn.*—Trochisci Ammonii Chloridi et Glycyrrhizæ. Each lozenge contains 3 grains of ammonium chloride and 3 grains of extract of liquorice.

AMMONII CITRAS

(Ammon. Cit.)

Ammonium Citrate

Ammonium citrate, $\text{C}_3\text{H}_4(\text{OH})(\text{COONH}_4)_3, \text{H}_2\text{O}$, is prepared by neutralising citric acid with ammonia. It occurs in the form of a very deliquescent, crystalline powder, which tends to lose ammonia and become partly converted into an acid salt.

Very **soluble** in water, the solution having a neutral or slightly acid reaction.

Standard.—Ammonium citrate, determined by the method of the British Pharmacopœia for Liquor Ammonii Acetatis Fortis, contains not less than 90 per cent. of $\text{C}_6\text{H}_5\text{O}_7(\text{NH}_4)_3, \text{H}_2\text{O}$; each millilitre of N/1 sodium hydroxide is equivalent to 0.08706 gramme of $\text{C}_6\text{H}_5\text{O}_7(\text{NH}_4)_3, \text{H}_2\text{O}$. Residue on gentle ignition, not more than 0.05 per cent. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million.

Action and Uses.—Ammonium citrate is a mild expectorant and diuretic; in very large doses it acts as a laxative. It is absorbed in part and converted in the tissues into the carbonate and ultimately into urea; hence, unlike the tartrates and citrates of the fixed alkalis, it does not increase the alkalinity of the urine. It should not, therefore, be administered to patients suffering from the uric acid diathesis. It is generally prescribed in the form of Liquor Ammonii Citratis Dilutus for the same purpose as solution of ammonium acetate. An effervescent alkaline solution of ammonium citrate, containing approximately 20 grains of ammonium citrate, is prepared by adding 1.1 grammes (17

grains) of citric acid to a solution of 1 gramme (15 grains) of ammonium carbonate.

Dose.—2 to 4 grammes ($\frac{1}{2}$ to 1 drachm).

Preparations

Liquor Ammonii Citratis Dilutus, B.P.C.—(Liq. Ammon. Cit. Dil.)—Dilute Solution of Ammonium Citrate. *Syn.*—Liquor Ammonii Citratis; Solution of Ammonium Citrate. Strong solution of ammonium citrate, 1 in 4, with distilled water. Dose.—8 to 24 millilitres (2 to 6 fluid drachms).

This solution, prepared from 12.5 per cent. w/v of citric acid and a sufficient quantity of ammonium carbonate, was included in the British Pharmacopœia, 1914, under the name of Liquor Ammonii Citratis.

Liquor Ammonii Citratis Fortis, B.P.C.—(Liq. Ammon. Cit. Fort.)—Strong Solution of Ammonium Citrate. It contains about 58 per cent. w/v of ammonium citrate. Dose.—2 to 6 millilitres ($\frac{1}{2}$ to 1½ fluid drachms).

AMMONII HIPPURAS

(Ammon. Hipp.)

Ammonium Hippurate

Ammonium hippurate, $\text{C}_6\text{H}_5\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{COONH}_4$, is the ammonium salt of hippuric acid or benzoylaminoacetic acid, $\text{C}_6\text{H}_5\cdot\text{CO}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{COOH}$, which may be obtained from the urine of herbivorous animals, or synthesised by the action of benzoyl chloride on aminoacetic acid. It may be prepared by suspending hippuric acid in 3 parts of water, warming gently, and adding sufficient strong solution of ammonia to render the mixture slightly alkaline to litmus. The liquid is then filtered through decolourising carbon and the filtrate concentrated to about one-third of its original volume. Finally, sufficient ammonia is added to produce a slightly alkaline reaction and the solution is poured into 7 volumes of acetone, with continuous stirring, the precipitated salt being collected and dried. It occurs in small, white, or brownish-white crystals, having no pronounced or unpleasant odour. When heated with strong solution of sodium hydroxide, ammonia is evolved and the hippuric acid is hydrolysed with formation of sodium benzoate, from which benzoic acid may be precipitated by adding an excess of hydrochloric acid. It is deliquescent, losing ammonia on exposure, with formation of hippuric acid, and should be **stored** in well-closed containers.

Soluble in water and in alcohol (1 in 20).

Standard.—Ammonium hippurate, determined by the Kjeldahl method, contains not less than 14.00 per cent. of N, equivalent to not less than 98 per cent. of $\text{C}_9\text{H}_8\text{O}_3\text{N}(\text{NH}_4)$. Residue on ignition, not more than 0.2 per cent. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. Dissolve 1 gramme in 40 millilitres of water, add 1 millilitre of nitric acid and filter; the filtrate complies with the limit test

for chlorides. Dissolve 1 gramme in 40 millilitres of water, add 1 millilitre of hydrochloric acid and filter; the filtrate complies with the limit test for sulphates.

Action and Uses.—Ammonium hippurate and other salts of hippuric acid have been given in the treatment of gouty conditions. They are said to lower blood pressure, and for this purpose are usually administered together with the other substances commonly used in the treatment of arterial hypertension.

Dose.—0.3 to 1.2 grammes (5 to 20 grains).

LITHII HIPPURAS.—Lithium hippurate, $C_6H_5 \cdot CO \cdot NH \cdot CH_2 \cdot COOLi \cdot 2H_2O$, occurs as glistening white plates or as a white powder, soluble in about 3 parts of water. Dose—0.3 to 1.2 grammes (5 to 20 grains).

POTASSII HIPPURAS. Potassium hippurate, $C_6H_5 \cdot CO \cdot NH \cdot CH_2 \cdot COOK \cdot H_2O$, is deliquescent and soluble in less than half its weight of water. Dose.—0.3 to 1.2 grammes (5 to 20 grains)

SODII HIPPURAS.—Sodium hippurate, $C_6H_5 \cdot CO \cdot NH \cdot CH_2 \cdot COONa$, is obtained, when crystallised from alcohol, with $1\frac{1}{2}$ molecules of water. It is soluble in about half its weight of water. Dose. 0.3 to 1.2 grammes (5 to 20 grains).

AMMONII IODIDUM

(Ammon. Iod.)

Ammonium Iodide

Ammonium iodide may be prepared by the action of ammonium carbonate on solution of iron iodide or zinc iodide. It occurs as a white, deliquescent, crystalline powder, which gradually becomes yellowish on exposure to air, owing to loss of ammonia and liberation of iodine. It has a sharp, saline taste, but no odour of iodine. It should be **stored** in well-stoppered, amber-coloured bottles, protected from light.

Soluble in water (1 in 1), alcohol (1 in 3) and glycerin (3 in 4).

Standard.—Ammonium iodide, determined by the method of the British Pharmacopœia for Potassii Iodidum, contains not less than 98 per cent. of NH_4I , calculated on the substance dried at 100° ; each millilitre of M/20 potassium iodate is equivalent to 0.0145 gramme of NH_4I . Loss on drying at 100° , not more than 5 per cent. Sulphated ash, not more than 0.1 per cent. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. 2 grammes complies with the limit test for sulphates.

Action and Uses.—Ammonium iodide in its action is similar to sodium and potassium iodides, but it is somewhat more rapidly absorbed from the alimentary canal. A 10 per cent. solution in glycerin is sometimes applied to enlarged tonsils.

Dose.—0.12 to 0.4 gramme (2 to 6 grains).

AMMONII PERSULPHAS

(Ammon. Persulph.)

Ammonium Persulphate

Ammonium persulphate may be prepared by the electrolysis of a solution of ammonium sulphate. The best yields are obtainable by keeping the solution cool and employing a high current density in a cell in which the anolyte is a saturated solution of ammonium sulphate and the catholyte a diluted sulphuric acid of specific gravity 1.3. It occurs in white, monoclinic crystals, and is stable when preserved in a dry condition. Solutions, when freshly prepared, possess powerful oxidising properties, but do not decolourise potassium permanganate or liberate iodine from potassium iodide. On standing or on heating, solutions decompose and give reactions characteristic of sulphates. Silver nitrate yields a black precipitate of silver peroxide, and when a concentrated solution containing a little ammonia is treated with silver nitrate a vigorous evolution of nitrogen takes place.

Soluble in water (1 in 2), with a considerable fall in temperature; insoluble in dehydrated alcohol.

Standard.—Ammonium persulphate contains not less than 98 per cent. of $(\text{NH}_4)_2\text{S}_2\text{O}_8$. Residue on ignition, not more than 0.1 per cent.

Assay.—Dissolve about 0.5 gramme, accurately weighed, in 10 millilitres of water, add 50 millilitres of N/10 oxalic acid and a solution of 0.2 gramme of silver sulphate in 20 millilitres of dilute sulphuric acid; heat on a water-bath until no more carbon dioxide is evolved, dilute to about 100 millilitres and titrate the excess of oxalic acid with N/10 potassium permanganate; each millilitre of N/10 oxalic acid is equivalent to 0.01141 gramme of $(\text{NH}_4)_2\text{S}_2\text{O}_8$.

Action and Uses.—Ammonium persulphate forms the starting point in the preparation of the persulphates and, on account of its powerful oxidising action, is employed largely as a reagent in the manufacture of carbon compounds, and in deodorising and decolourising oils, fats and soaps. The salt is used also in photography for reducing dense negatives; it acts by oxidising and then dissolving part of the silver. Ammonium persulphate removes the stains caused by pyrogallol.

AMMONII PHOSPHAS

(Ammon. Phosph.)

Ammonium Phosphate

Ammonium phosphate is prepared by the combination of ammonia and phosphoric acid. The salt is a mixture of diammonium hydrogen phosphate, $(\text{NH}_4)_2\text{HPO}_4$, and ammonium dihydrogen phosphate,

$\text{NH}_4\text{H}_2\text{PO}_4$. It occurs in colourless, prismatic crystals which lose ammonia on exposure to air. Its aqueous solution is neutral or alkaline to litmus. It should be **stored** in well-closed containers.

Soluble in water (1 in 2); insoluble in alcohol.

Standard.—Ammonium phosphate yields not less than 22 per cent. of NH_3 . Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. 1 gramme complies with the limit tests for chlorides, sulphates and iron.

Assay.—To about 1 gramme, accurately weighed, dissolved in 200 millilitres of water, add 25 millilitres of a 25 per cent. solution of sodium hydroxide in water. Distil the liberated ammonia into 50 millilitres of N/2 sulphuric acid and titrate the excess of acid with N/2 sodium hydroxide using methyl red as indicator; each millilitre of N/2 sulphuric acid is equivalent to 0.008516 gramme of NH_3 .

Action and Uses.—Ammonium phosphate has a typical saline action and is used mainly for its diuretic effect. It is not so easily absorbed as most of the ammonium salts; during excretion it renders the urine slightly more acid. It is occasionally administered in mixtures.

Dose.—0.3 to 1.2 grammes (5 to 20 grains).

AMMONII SALICYLAS

(Ammon. Salicyl.)

Ammonium Salicylate

Ammonium salicylate, $\text{C}_6\text{H}_4(\text{OH})\cdot\text{COONH}_4$, may be obtained by the interaction of ammonia and salicylic acid. It occurs in colourless, almost odourless crystals, or as a white, crystalline powder with a sweetish taste.

Soluble in water (1 in 1) and alcohol (1 in 2.5).

Standard.—Ammonium salicylate, determined by the method for Ammonii Benzoas, contains not less than 98 per cent. of $\text{C}_7\text{H}_5\text{O}_3(\text{NH}_4)$; each millilitre of N/2 sulphuric acid is equivalent to 0.07754 gramme of $\text{C}_7\text{H}_5\text{O}_3(\text{NH}_4)$. Ash, not more than 0.1 per cent. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million.

Action and Uses.—The action of this salt is similar to that of sodium salicylate, except that the ammonium salt is more quickly absorbed into the system, but it is a fallacy to suppose that ammonium salicylate is less depressant to the central nervous system than is sodium salicylate. It may be **administered** in mixtures, powders, or cachets, but, in consequence of its liability to cause gastric disturbance, it should not be given too frequently or in too large a dose.

Dose.—0.3 to 1 gramme (5 to 15 grains).

AMMONII SULPHAS

(Ammon. Sulph.)

Ammonium Sulphate

Ammonium sulphate is obtained from the ammoniacal liquor of the gas works or from synthetic ammonia by neutralisation with sulphuric acid, and purification by subsequent crystallisation. It occurs in colourless, transparent, rhombic prisms which are odourless and have a sharp, saline taste. It is permanent in the air and its aqueous solution has a neutral reaction. It melts at 140° and decomposes at about 260° .

Soluble in water (about 3 in 4); insoluble in alcohol.

Standard.—Ammonium sulphate leaves, on strongly heating, not more than 0.02 per cent. of residue. Arsenic limit, 10 parts per million. Lead limit, 20 parts per million. 5 grammes complies with the limit test for chlorides. 1 gramme complies with the limit test for iron.

Action and Uses.—The sulphate differs from other ammonium salts in that it is absorbed with difficulty from the intestines, and hence acts as a mild saline aperient. It is rarely employed in medicine. It is used for fractional precipitation of proteins from solution. Crude ammonium sulphate is largely used as a fertiliser.

Dose.—0.3 to 1.2 grammes (5 to 20 grains).

AMMONII TARTRAS

(Ammon. Tart.)

Ammonium Tartrate

Ammonium tartrate, $(\text{CHOH} \cdot \text{COONH}_4)_2$, may be prepared by neutralising a solution of tartaric acid with solution of ammonia and evaporating, keeping the solution neutral by the addition of ammonia. It occurs in colourless, somewhat efflorescent crystals.

Readily **soluble** in water.

Standard.—Ammonium tartrate contains not less than 98 per cent. of $\text{C}_4\text{H}_4\text{O}_6(\text{NH}_4)_2$. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. 1 gramme complies with the limit tests for chlorides and sulphates.

Assay.—Dissolve 2 grammes, accurately weighed, in 50 millilitres of water, add 12 millilitres of solution of formaldehyde previously neutralised to phenolphthalein and titrate with N/2 sodium hydroxide using phenolphthalein as indicator; each millilitre of N/2 sodium hydroxide is equivalent to 0.04603 gramme of $\text{C}_4\text{H}_4\text{O}_6(\text{NH}_4)_2$.

Action and Uses.—Ammonium tartrate has mild, diuretic and diaphoretic properties. Its chief use in medicine is in the treatment by irrigation of lime burns of the conjunctiva. For this purpose a 10 per cent. neutral solution is used.

AMYDRICAINÆ HYDROCHLORIDUM

(Amydricain. Hydrochlor.)

Amydricaine Hydrochloride

Amydricaine hydrochloride is benzoyltetramethyldiaminodimethylethylcarbinol hydrochloride, $\text{C}_6\text{H}_5\cdot\text{COOC}(\text{C}_2\text{H}_5)[\text{CH}_2\text{N}(\text{CH}_3)_2]_2\cdot\text{HCl}$. It occurs in the form of a white, crystalline powder. The aqueous solution (1 in 50) produces an orange-yellow, crystalline precipitate with potassium dichromate solution, which is soluble in hydrochloric acid, a violet, crystalline precipitate, turning brown on standing, with potassium permanganate solution, and a white, crystalline precipitate with potassium iodide solution. 5 millilitres of an aqueous solution (1 in 50) with 2 drops of dilute hydrochloric acid and 2 drops of a 10 per cent. sodium nitrite solution, mixed with a solution of 0·2 gramme of betanaphthol in 10 millilitres of 10 per cent. sodium hydroxide solution, produces no deep red colour or precipitate (distinction from benzocaine, orthocaine and certain other local anaesthetics). The base separates as a liquid from the aqueous solution on adding a slight excess of ammonia.

Soluble in water (1 in 1) and alcohol (1 in 4).

Standard.—Amydricaine hydrochloride melts at about 169° . Loss on drying at 100° , not more than 2 per cent. Ash, not more than 0·1 per cent.

Action and Uses.—Amydricaine hydrochloride is a local anaesthetic and is used as a substitute for cocaine. Its toxicity equals that of cocaine and is greater than that of most other cocaine substitutes. Applied to the eye it has about one-fourth the anaesthetic effect of cocaine. Its action is rapid, without causing mydriasis, increase of intra-ocular tension, or irritation. Solutions of 2 to 4 per cent. w/v strength are employed. In aural and nasal surgery 5 per cent. w/v solutions are used. Combined with solution of adrenaline, hæmorrhage is lessened and absorption delayed, thus minimising the risk of poisoning. For hypodermic use in dentistry and in minor operations 0·5 to 2 per cent. w/v solutions are employed. It causes hyperæmia by paralysis of the vessel wall and may be extremely irritating. Amydricaine hydrochloride is a useful local anaesthetic to the stomach and is recommended for prophylactic use to prevent post-operative vomiting. Solutions for **injection** may be sterilised

by tyndallisation or by filtration. It is **incompatible** with silver nitrate.

Dose.—0.003 to 0.03 gramme ($\frac{1}{20}$ to $\frac{1}{2}$ grain).

AMYGDALA AMARA

(Amygdal. Amar.)

Bitter Almond

Bitter almond consists of the dried ripe seeds of *Prunus communis* Arcang. var. *amara* Schneid. (Fam. Rosaceæ), a tree which is cultivated in the countries bordering on the Mediterranean. It is exported chiefly from Morocco and Sicily.

The seeds are broadly ovate and somewhat laterally compressed; they are exalbuminous, about 2 centimetres long and 1.25 centimetres broad. The seed coat is thin, cinnamon-brown and scurfy; the hilum is situated on the edge near the pointed end of the seed. From the chalaza which lies at the rounded, broader end, a number of veins radiate. The embryo is straight and consists of two thick, plano-convex, oily cotyledons, enclosing a small plumule and radicle. The taste is bitter, and a mingled odour of benzaldehyde and hydrocyanic acid is evolved when the seeds are triturated with water.

The diagnostic **microscopical** characters are the lignified, uniformly thickened, giant cells of the seed coat, with pitted radial walls, sub-rectangular in outline in transverse section and usually over 100 microns in diameter; abundant aleurone grains, the larger of which often contain rosette crystals or, occasionally, prisms of calcium oxalate; the presence of much fixed oil.

Bitter almond **contains** fixed oil (about 50 per cent.), the bitter, crystalline glycoside, amygdalin (about 3 to 4 per cent.), and at least two enzymes, emulsin and lactase, together with proteins. It yields about 0.5 to 0.8 per cent. of essential oil, which may contain from 4 to 7 per cent. of hydrocyanic acid.

GROUND BITTER ALMOND contains the elements of the whole seed with the exception of the testa, of which only traces are present. Bitter almond meal is the powdered cake obtained after removal of the fixed oil by expression.

Standard.—Bitter almond contains not more than 2 per cent. of foreign organic matter. Ash, not more than 4 per cent.

Action and Uses.—The action of bitter almond differs from that of the sweet variety owing to the presence of hydrocyanic acid. Unpleasant symptoms may arise, especially in children, from eating relatively small quantities. Lotio Amygdalæ Amaræ forms a suitable basis for soothing skin lotions, especially to allay the smarting of sunburn.

Preparation

Lotio Amygdalæ Amaræ, B.P.C.—(Lot. Amygdal. Amar.)—Lotion of Bitter Almond. *Syn*—Mistura Amygdalæ Amaræ; Bitter Almond Mixture. Bitter almond, 7.5 per cent. w/v, with distilled water.

AMYGDALA DULCIS

(Amygdal. Dulc.)

Sweet Almond*Synonym*—Jordan Almonds.

Sweet almond consists of the dried ripe seeds of *Prunus communis* Arcang. var. *dulcis* Schneid. (Fam. Rosaceæ), a tree which is cultivated in all countries bordering on the Mediterranean, but especially in Italy, France, Spain and the Balearic Islands.

The seeds are nearly oblong in outline and somewhat laterally compressed, exalbuminous and about 3 centimetres long and 1.25 centimetres broad. The seed coat is coarsely and longitudinally wrinkled, cinnamon-brown and scurfy. The hilum extends along the edge of the seed from near the pointed end to about half its length; from the chalaza, which lies at the obtuse end, a number of veins radiate. The embryo is of the same shape as the seed, and consists of two white, plano-convex, oily cotyledons enclosing a short radicle and plumule. The taste is bland; on trituration with water an emulsion is formed which is free from any marked odour.

The diagnostic **microscopical** characters are the lignified, giant cells of the seed coat, with pitted radial and inner tangential walls, rectangular in outline, many having arched outer walls usually over 100 microns in diameter; much fixed oil; abundant aleurone grains, the larger of which frequently contain a rosette of calcium oxalate, often with a conspicuous central point.

Sweet almond **contains** fixed oil (45 to 50 per cent.), and about 20 per cent. of proteins including the mixture of enzymes known as emulsin.

GROUND SWEET ALMOND contains the whole elements of the seed with the exception of the seed coats, of which only traces are present. Almond flour or meal is obtained by powdering the cake left after removal of oil by expression; it contains about 8 per cent. of residual oil and about 40 per cent. of protein.

Substitutes.—Valencian, Sicilian, Mogador, Mazagan, Majorcan and Persian are varieties of sweet almonds which are shorter and broader than Jordan almonds; they resemble bitter almonds, but are rather larger and less flattened.

Standard.—Sweet almond contains not more than 1 per cent. of foreign organic matter. Ash, not more than 2 per cent. Prepare a 10 per cent. w/v extract of freshly powdered guaiacum resin in alcohol (95 per cent.); saturate a strip of filter paper of medium texture with the solution and allow to dry slowly; select a number of seeds to be tested, cut each in half to give a smooth surface; saturate the filter paper with a 0.1 per cent. w/v solution of copper sulphate, lay it upon a glass or porcelain plate and quickly place one half of each seed on the sensitised paper to make close contact, allowing them to remain there for ten minutes; no blue stain is produced (absence of bitter almond).

Action and Uses.—Sweet almond is demulcent; a mixture made

from it, such as *Mistura Amygdalæ*, affords a useful vehicle for cough medicines and in which to suspend terebene and similar drugs not readily miscible with water. *Pulvis Amygdalæ Compositus* is used as an emulsifying agent and for the preparation of demulcent cough mixtures. Almond flour or meal, being free from starch, is suitable for preparing diabetic foods.

Preparations

Lotio Rosæ, B.P.C.—(Lot. Ros.)—Rose Lotion. *Syn*—Lac Rosæ; Milk of Roses. Sweet almond, 1 in 10, with curd soap, white beeswax, almond oil, oils of bergamot, lavender and rose, alcohol (90 per cent.) and rose water.

Mistura Amygdalæ, B.P.C.—(Mist. Amygdal.)—Almond Mixture. Compound powder of almond, 1 in 8, in distilled water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

This mixture was included in the British Pharmacopœia, 1914.

Pulvis Amygdalæ Compositus, B.P.C.—(Pulv. Amygdal. Co.)—Compound Powder of Almond. Sweet almond, 60 per cent., with sucrose and acacia.

This powder was included in the British Pharmacopœia, 1914.

AMYLENI HYDRAS

(Amylen. Hydr.)

Amylene Hydrate

Synonyms—Amylene Hydratum; Tertiary Amyl Alcohol.

Amylene hydrate is dimethylethylcarbinol, $(\text{CH}_3)_2\text{C}_2\text{H}_5\text{C}\cdot\text{OH}$, and may be prepared by treating trimethylethylene (amylene) with sulphuric acid, and subsequently distilling the amylene sulphate with an alkali. It occurs as a clear, volatile liquid with a penetrating odour, resembling that of camphor and peppermint, and has a pungent taste. On cooling to a low temperature it solidifies in acicular crystals, which are hygroscopic. Oxidation with chromic acid converts it into acetic acid and acetone.

Soluble in water (1 in 8), and in all proportions of alcohol, ether, chloroform and glycerin.

Standard.—Amylene hydrate boils between 97° and 103° . Specific gravity, 0.812 to 0.815. On treating 20 millilitres of an aqueous solution (1 in 20) with 2 drops of potassium permanganate solution, decolourisation is not complete within ten minutes (limit of amyl alcohol). Another portion of the solution does not reduce an ammoniacal solution of silver nitrate within ten minutes when heated on a water-bath (absence of aldehyde). On shaking 8 millilitres with 0.6 gramme of anhydrous copper sulphate, no pronounced blue colour is produced (absence of water).

Action and Uses.—Amylene hydrate is a safe hypnotic resembling

paraldehyde in its action, but it is two or three times as powerful and depresses the heart more. It shares the disadvantage of frequently causing stimulation of the central nervous system; marked excitement may therefore precede hypnosis, and on this account amylene hydrate is among the lesser used hypnotics. It is not so powerful as chloral hydrate, but is less depressing to the heart. Amylene hydrate produces a marked fall in the temperature. Like paraldehyde, it is excreted mainly by the lungs. It may be **administered** in capsules, or in a mixture, suitably flavoured.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

AMYLIS ACETAS

(Amyl. Acet.)

Amyl Acetate

Amyl acetate, $\text{CH}_3\cdot\text{COOC}_5\text{H}_{11}$, may be prepared by the action of glacial acetic acid on amyl alcohol boiling between 128° and 132° , in the presence of a small quantity of sulphuric acid. The ethereal layer is separated, well washed with water, again separated, and rectified by distillation. It is a mixture of isomeric acetates and occurs as a colourless, mobile, neutral and inflammable liquid, having a powerful pear-like odour. After long keeping the liquid becomes acid in reaction; this, however, does not interfere with its employment as a fruit essence, but, if necessary, it may be treated with sodium bicarbonate and redistilled.

Very slightly **soluble** in water; soluble in all proportions of alcohol, ether, ethyl acetate and amyl alcohol.

Standard.—Not less than 90 per cent. distils between 135° and 145° . Specific gravity, 0.870 to 0.876.

Action and Uses.—Amyl acetate is not employed therapeutically. A compound alcoholic solution, known in commerce as essence of jargonelle pear, is used as a flavouring agent. Amyl acetate is a solvent for celluloid, resins and pyroxylin, and is used with other solvents in the preparation of lacquers, varnishes and collodions, and liquid plasters.

AMYLIS NITRIS

(Amyl. Nitris)

Amyl Nitrite

Amyl nitrite is a mixture consisting chiefly of nitrites of

methyl-3-butanol-1, $(\text{CH}_3)_2\text{CH}\cdot\text{CH}_2\cdot\text{CH}_2\text{OH}$, and methyl-2-butanol-1, $\text{C}_2\text{H}_5\cdot\text{CH}(\text{CH}_3)\text{CH}_2\text{OH}$, with other nitrites of the homologous series. It may be prepared by acting on amyl alcohol or fusel oil, distilled between 128° and 132° , with sodium nitrite and sulphuric acid. It occurs as a clear, yellow liquid with a fragrant odour, and an aromatic pungent taste. It is inflammable and very volatile. Amyl nitrite should be **stored** in well-closed containers in a cool, dark place.

Insoluble in water; miscible with alcohol and ether.

Standard, B.P.—Amyl nitrite contains not less than 90 per cent. w/w of nitrites, calculated as $\text{C}_5\text{H}_{11}\text{O}_2\text{N}$. Specific gravity, 0.874 to 0.884. Not less than 85 per cent. distils between 90° and 100° . Residue on evaporation, not more than 0.01 per cent. w/v. It complies also with limit tests for acid and aldehyde.

Action and Uses.—Amyl nitrite when inhaled depresses all plain muscle throughout the body, its effects being most pronounced on the circulatory system. The arterioles dilate and the blood pressure falls very considerably. Owing to this action it flushes the face and causes the head and neck to perspire. It is rapidly absorbed by the great area of lung capillaries, so that the onset of its action is almost immediate, but the effect usually lasts for two or three minutes only.

The chief use of amyl nitrite is in the treatment of an attack of angina pectoris associated with high blood pressure, when it affords relief by the dilatation of the coronary vessels. It is contra-indicated in coronary thrombosis, and it should not be used, therefore, indiscriminately in attacks of angina pectoris associated with dyspnoea. It has been used in asthma and sea-sickness, to relieve the spasm of croup and whooping cough, and in the treatment of raised blood pressure, but in these conditions, by reason of its transient action, it is sometimes replaced by sodium nitrite. If inhaled during the aura of epileptic seizure it will in certain cases abort the attack.

Amyl nitrite is usually **administered** by inhalation, but in cases where inhalation cannot be performed it may be used as a hypodermic injection. For inhalation it is supplied in small glass capsules containing from 0.12 to 0.3 millilitre (2 to 5 minims), covered with cotton wool and silk. The glass should be broken by pressure, the vapour being cautiously and not too suddenly inhaled; as much as 0.6 millilitre (10 minims) is sometimes used. In handling amyl nitrite, inhalation of the vapour should be avoided. In cases of **poisoning** from oral administration, an emetic of mustard or zinc sulphate should be given, followed by injection of adrenaline or ephedrine. The recumbent position should be maintained and oxygen, either alone or with 5 per cent. of carbon dioxide, should be given, or artificial respiration applied if necessary. In cases of poisoning from inhalation the emetic should be omitted.

Dose.—0.12 to 0.3 millilitre (2 to 5 minims), by inhalation.

AMYLOCAINÆ HYDROCHLORIDUM

(Amylocain. Hydrochlor.)

Amylocaine Hydrochloride

Amylocaine hydrochloride is the hydrochloride of the benzoyl ester of methylethyldimethylaminomethylcarbinol, $\text{C}_6\text{H}_5\cdot\text{COOC}(\text{CH}_3)(\text{C}_2\text{H}_5)(\text{CH}_2\text{N}(\text{CH}_3)_2)$, which may be prepared from dimethylaminoacetone by the action of magnesium ethylbromide. It occurs as a white, crystalline, odourless powder with a bitter taste, causing temporary anæsthesia of the tongue. The aqueous solution is neutral to congo-red, but faintly acid to litmus, and gives the reactions of chlorides. The base is precipitated as a non-crystallisable oil on adding solution of sodium carbonate or sodium hydroxide to the aqueous solution, and can be extracted with light petroleum. Amylocaine hydrochloride slowly decolourises potassium permanganate solution, but, unlike cocaine, no crystalline precipitate is produced. It may be distinguished from orthocaine by the formation of a precipitate on the addition of iodine solution or solution of potassio-mercuric iodide. The latter reaction also distinguishes it from benzocaine. It should be **stored** in a dark place.

Soluble in water (1 in 2) and dehydrated alcohol (1 in 3); almost insoluble in ether.

Standard, B.P.—Amylocaine hydrochloride has a melting-point of 177° to 179° . Ash, not more than 0.1 per cent. It complies also with a test for the absence of readily carbonisable substances.

Action and Uses.—Amylocaine hydrochloride is employed as a local anæsthetic. On account of its irritant action it is less useful for this purpose than procaine hydrochloride and, owing to the fact that it dilates the blood vessels, its use with adrenaline is unsatisfactory. Its value when applied to mucous membranes is markedly inferior to that of cocaine. It is rapidly and completely absorbed when given either by the mouth or subcutaneously, and the greater part is destroyed by the liver, practically none being excreted in the urine.

For the production of spinal anæsthesia, amylocaine hydrochloride is less toxic than cocaine. For this purpose the two solutions in common use are (1) amylocaine hydrochloride, 0.1 gramme, sodium chloride, 0.1 gramme, distilled water, 1 millilitre; (2) amylocaine hydrochloride, 0.1 gramme, dextrose, 0.1 gramme, distilled water, 2 millilitres. The dosage for intraspinal use is from 0.02 to 0.06 gramme and it may be combined with either strychnine hydrochloride, 0.001 to 0.002 gramme, or caffeine, 0.1 gramme, and sodium benzoate, 0.1 gramme. Strychnine and caffeine, when added, are for the purpose of combating the collapse, low blood pressure and respiratory failure that may occur. Given in the above doses amylocaine hydrochloride produces complete paralysis of the posterior nerve roots, but does not paralyse the anterior motor roots. The anæsthesia appears in a

few minutes and lasts from forty minutes to two hours. For local infiltration anæsthesia, 0·5 to 2 per cent. w/v solutions are employed, and for ophthalmic instillation, solutions of 2 to 4 per cent. w/v are used. A solution for **injection** may be sterilised by tyndallisation or by filtration, and the containers should comply with the tests for limit of alkalinity of glass.

Dose.—0·02 to 0·05 gramme ($\frac{1}{3}$ to $\frac{3}{4}$ grain), by mouth or by subcutaneous injection; 0·02 to 0·1 gramme ($\frac{1}{3}$ to $1\frac{1}{2}$ grains), by intrathecal injection.

Preparation

Unguentum Adrenalinæ et Amylocainæ Compositum, B.P.C.—(Ung. Adrenal. et Amylocain. Co.) Compound Ointment of Adrenaline and Amylocaine Adrenaline, 1 in 14,000, as benzoate, amylocaine hydrochloride and benzocaine, of each 1 per cent., and liquid extract of hamamelis, 7·5 per cent. v/w, in wool fat and yellow soft paraffin.

AMYLUM

(Amylum)

Starch

Synonyms—Maize Starch; Corn Starch.

Starch is prepared from the grains of maize, *Zea Mays* Linn. (Fam. Gramineæ). It is manufactured chiefly in the United States of America, which produces about nine-tenths of the world's supply; comparatively small quantities are produced in Germany, Canada and Great Britain.

It occurs as a fine, white, odourless and tasteless powder, or in irregular angular masses, known as "crystal" starch, which are readily powdered. Examined **microscopically**, the granules are seen to be polyhedral, sub-spherical or, occasionally, muller-shaped; they are from about 10 to 20 or up to 25 microns in diameter. The hilum is represented by a central, triangular, or 2 to 5-rayed fissure, and striations are not visible. It shows a well-marked cross by polarised light. Starch is insoluble in cold water, in alcohol and in other organic solvents; when 1 gramme is boiled with 15 millilitres of water and the mixture cooled, a translucent, whitish, gelatinous mass is formed. Mucilage of starch, prepared by boiling starch with a large volume of water, gives, on the addition of a few drops of solution of iodine, a deep blue colour, which disappears on warming and reappears on cooling.

Starch **contains** the polysaccharide, amylose, and also amylopectin and amylo-hemicellulose.

Standard, B.P.—Starch loses on drying at 100° not more than 14 per cent. of its weight. Ash, not more than 0·5 per cent.

Action and Uses.—Starch soaks up secretions and helps to render injured parts less liable to bacterial infection. As a dusting powder

for application to chafings and excoriations, it is used either alone or mixed with zinc oxide, boric acid or other similar substances. Boiled with water it may be employed as an emollient for the skin. As a protective application in skin diseases it may be used in the form of *Glycerinum Amyli*. Mucilage of starch is the basis for many enemata and is an antidote for poisoning by iodine; it should be freshly prepared as required. Boiled with sufficient water to form a stiff paste, starch forms an excellent poultice, which may be improved by the addition of 6 per cent. of boric acid.

AMYLUM ORYZÆ.—Rice starch is prepared from grains of rice, *Oryza sativa* Linn. (Fam. Gramineæ). The granules occur singly and in compound grains. Single granules are polyhedral and are usually from 5 to 8 or up to 12 microns in diameter; the hilum is sometimes evident as a minute central point, spindle-shaped and lemon-shaped granules are absent (distinction from oat starch). The compound grains are ovate, usually from about 12 to 30 microns long and 7 to 20 microns wide; they contain from about 2 to 150 components. The constituents are similar to those of maize starch.

AMYLUM TRITICI.—Wheat starch is manufactured from grains of wheat, *Triticum aestivum* Lam. (Fam. Gramineæ). The granules are lenticular and, in outline, are circular, oval or sub-reniform; the hilum appears as a central point or, if the granule is on its edge, as a line. The granules are mostly simple, the smaller ones being usually from 5 to 10 microns and the larger ones from 20 to 25 or up to 50 microns in greatest width. A few compound granules of 2 to 4 components are present; there are always more than 400 granules per milligram having a maximum diameter exceeding 40 microns (distinction from barley starch). When viewed in polarised light, a dull cross of the maltese shape is seen. The constituents of wheat starch are similar to those of maize starch.

AMYLUM SOLANI.—Potato starch is manufactured from the tubers of the potato, *Solanum tuberosum* Linn. (Fam. Solanaceæ). The granules are ovoid, irregularly ovoid, or sub-spherical, and often somewhat flattened; the hilum is a point towards the narrower end of the granule, and has an eccentricity of $\frac{1}{4}$ to $\frac{1}{2}$; the striations are well-marked and concentric; some rings appear darker than others. The granules are mostly simple, the sub-spherical ones measuring from about 10 to 35 microns and the ovoid ones from 30 to 100 microns. A few compound granules of from 2 to 3 components are always present. The granules show a well-marked cross when examined in polarised light; they contain not more than 20 per cent. of moisture, and the remainder of the granule consists of 66 per cent. of polymerised amylose and 33 per cent. of amylopectin.

AMYLUM SOLUBILE. Soluble starch is prepared from the starch of the potato, *Solanum tuberosum* Linn. (Fam. Solanaceæ), by a process of treatment with dilute hydrochloric acid, carefully adjusted so as to destroy the gelatinising power of the starch. Soluble starch shows the microscopical appearance almost unchanged of potato starch, but has acquired the property of being readily soluble in hot water to form a transparent, mobile liquid. A 2 per cent. solution, prepared by mixing 1 part with 5 parts of cold water, diluting to 50 parts with boiling water and heating to 100° for two minutes, gives an incomplete reduction when 10 millilitres is boiled with 0.1 millilitre of Fehling's solution, and gives a deep blue colour when one drop of solution of iodine is added to 10 millilitres. The reagent of the British Pharmacopœia loses at 100° not more than 15 per cent. of its weight, and complies with the limit test for chlorides.

Preparations

Glycerinum Amyli, B.P.—(*Glycer. Amyl.*) Glycerin of Starch. *Syn.*—Glycerite of Starch. Starch, 8.5 per cent., heated in glycerin and water until gelatinised. It should be stored in well-closed containers.

Pulvis Zinci et Amyli, B.P.C.—(Pulv. Zinc. et Amyli)—Zinc and Starch Powder. Equal parts of zinc oxide and starch.

Pulvis Zinci et Amyli Compositus, B.P.C.—(Pulv. Zinc. et Amyli Co.)—Compound Zinc and Starch Powder. Equal parts of zinc oxide, starch, boric acid and purified talc, perfumed with oil of geranium.

ANCHUSA

(Anchus.)

Alkanna

Synonyms—Alkanet Root; Dyer's Alkanet.

Alkanna is the dried root of *Alkanna tinctoria* Tausch. (Fam. Boraginaceæ), a deciduous herbaceous plant with a perennial rootstock, growing in sandy soil in Southern Europe, Hungary and Asiatic Turkey, the chief supplies coming from Hungary.

The tapering roots are simple, deep reddish-purple in colour, varying from about 10 to 15 centimetres in length and from 1 to 2 centimetres in thickness near the crown, to which are attached the remains of leaves, bearing whitish, bristly hairs. The roots have little odour or taste and readily colour the fingers when handled. The external surface is deeply furrowed and the outer layers readily exfoliate in papery strips; the furrows are often so deep as to separate the whitish wood into isolated strands, these changes being due to the formation of red colouring matter and ultimate destruction of the parenchymatous tissue.

Alkanna **contains** two substances of an acid nature, namely, anchusic and alkannic acids, one of which is readily soluble in oils and fats and is changed from red to blue by alkalis. By extraction with light petroleum it yields about 3 per cent. of a red, amorphous substance known as alkannin, $C_{16}H_{14}O_4$, which gives a blue colour with alkalis.

Substitutes.—The root of *Lawsonia alba* Lam. is sometimes known as "true" alkanet root. Many other roots contain a somewhat similar red colouring matter, e.g. the roots of *Onosmodium echinoides* Linn. and of *Macrotomia Cephalotes* Boiss., the latter, known as Syrian alkanet, yields to alcohol about 9 per cent. of coloured extractive; it is frequently found in commerce and is a valuable colouring agent.

Standard.—Alkanna contains not more than 2 per cent. of foreign organic matter. Acid-insoluble ash, not more than 10 per cent.

Action and Uses.—Alkanna is used for colouring toilet preparations of an oily or spirituous nature. "Red oil" may be prepared by digesting 1 part of alkanna in 7 parts of liquid paraffin. The red colouring matter in alcoholic solution is used as a microscopical reagent for the detection of oils and fatty matter.

ANETHOLUM

(Anethol.)

Anethole

Anethole, or *p*-methoxypropenylbenzene, $\text{C}_6\text{H}_4(\text{OCH}_3)\text{C}_3\text{H}_5$, may be obtained from oil of anise. It occurs as a white, crystalline mass having an odour of anise and an intensely sweet taste. When melted it is a strongly refractive, colourless liquid. Evaporated on a water-bath it leaves nearly 10 per cent. of a non-volatile, odourless polymer. The action of air and light induces changes in anethole, causing it to become yellow, to acquire the odour of anisaldehyde and a bitter, unpleasant taste, and lowers the congealing-point until finally it ceases to crystallise. It boils at about 234° . It should be **stored** in well-stoppered, amber-coloured bottles, protected from light and air.

Slightly **soluble** in water; readily soluble in ether and chloroform, and forms a clear solution with two volumes of alcohol.

Standard.—Anethole congeals or freezes between 21° and 22° . **Re-**melting-point, 22° to 23° . Specific gravity at 25° , 0.984 to 0.986. Refractive index at 25° , 1.558 to 1.561.

Action and Uses.—Anethole has the action of essential oils generally, and may be used as a carminative and expectorant.

Dose.—0.03 to 0.18 millilitre ($\frac{1}{2}$ to 3 minims).

ANETHUM

(Aneth.)

Dill

Synonyms—Anethi Fructus; Dill Fruit.

Dill consists of the dried ripe fruits of *Anethum graveolens* Linn. (Fam. Umbelliferae), an annual herb cultivated in Germany and also, to a smaller extent, in England.

The cremocarps are broadly oval and glabrous, about 3 to 4 millimetres long, 2 to 3 millimetres broad and 1 millimetre thick, being so strongly compressed dorsally as to appear almost flat. They are chocolate-brown in colour and each mericarp has three inconspicuous pale brown, dorsal ridges, the two lateral ridges being yellowish and prolonged to form membranous wings. The flat commissural surface shows the carpophore as a pale line down the centre. A transverse section through a mericarp shows usually six vittae, four being dorsal and two commissural, and five vascular strands, three being small and situated dorsally, the two larger strands being in the wings. The drug has a characteristic and pleasantly aromatic odour and taste.

The diagnostic **microscopical** characters of the fruit are the striated cuticle of the outer epidermis; the small amount of the lignified reticulate parenchyma of the mesocarp; the inner epidermis, composed of tubular cells frequently with wavy walls; the thick-walled parenchyma of the endosperm, containing fixed oil, aleurone grains and micro-sphæroidal crystals of calcium oxalate.

Dill **contains** about 3 to 4 per cent. of volatile oil, together with fixed oil and mucilage.

Substitute.—Considerable quantities of Indian dill, *Anethum Sowa* Roxb., are imported from Bombay. These fruits are distinguished by being narrower and more strongly convex, as well as by the paler colour of the dorsal ridges, which renders them much more conspicuous than those of the official fruit. Moreover, the mericarps are usually united and attached to a small pedicel.

Standard, B.P.—Dill contains not more than 2 per cent. of foreign organic matter. Ash, not more than 11 per cent.

Dill, in powder (*Pulvis Anethi* : *Pulv. Aneth.*), contains the constituents and possesses the diagnostic microscopical characters of *Anethum*, and complies with the limit for ash of the unground drug.

Action and Uses.—The action of dill depends on the essential oil which it contains (see *Oleum Anethi*). It is used in mixtures in the form of *Aqua Anethi* which is a common domestic remedy for the flatulence of infants and is a useful vehicle for children's medicines generally.

Preparations

Aqua Anethi Concentrata, B.P.—(*Aq. Aneth. Conc.*)—Concentrated Dill Water. Oil of dill, 1 in 50. One part added to 39 parts of distilled water yields a preparation which is approximately equivalent in strength to distilled dill water, but contains 1·5 per cent. v/v of alcohol (90 per cent.). Dose.—0·3 to 1 millilitre (5 to 15 minims).

* *This concentrated water, prepared with 6 per cent. v/v of oil of dill, was included in the British Pharmaceutical Codex, 1923.*

Aqua Anethi Destillata, B.P.—(*Aq. Aneth. Dest.*)—Distilled Dill Water. Dill, 1 in 10. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

ANGELICÆ FRUCTUS

(*Angel. Fruct.*)

Angelica Fruit

Synonym—Angelica Seeds.

Angelica fruit consists of the dried, ripe fruits, of *Angelica Archangelica* Hoffm. (Fam. Umbelliferæ), a biennial plant indigenous to Northern Europe and Asia, and cultivated in Italy, France, Germany, and elsewhere.

The fruit is yellowish-white, oval and markedly compressed dorsally, about 7 millimetres long and 5 millimetres wide; the base has a shallow notch, and the apex bears five minute calyx teeth and the remains

of the style; the three dorsal ridges are prominent and bluntly keeled, and the two lateral ones are extended to form membranous margins. The mericarps are usually separated and the brown seed lies loosely in the cavity of the mericarp. The transverse section of the pericarp is divisible into an outer portion which is free from vittæ, and an inner portion containing ten to thirty vittæ in each mericarp. The odour is aromatic, and the taste aromatic and pungent.

Angelica fruit **contains** volatile oil, of which it yields about 1 per cent. (specific gravity, 0.856 to 0.900; specific rotation $+11^{\circ}$ to $+16^{\circ}$). The oil varies only very slightly in odour and taste from that of the root or fresh herb. It contains phellandrene and other terpenes, with esters of methylethylacetic (valeric) and hydroxymyristic acids. The ash of the fruit averages about 7 per cent.

Substitutes.—The fruits of other species of *Angelica* are probably used in the production of volatile oil, e.g. *A. lucida* Linn., and *A. sylvestris* Linn., in Italy; *A. atropurpurea* Linn., in N. America; *A. sylvestris* Linn. and *A. refracta* A. Schmidt, in Japan. The oils obtained from the Japanese varieties are very different from that of *A. Archangelica*.

Standard. Angelica fruit contains not more than 3 per cent. of foreign organic matter. Acid-insoluble ash, not more than 1 per cent.

Action and Uses.—The properties of angelica fruit resemble those of angelica root. It is used in the preparation of Tinctura Antiperiodica.

ANGELICÆ RADIX

(Angel. Rad.)

Angelica Root

Angelica root consists of the dried rhizome and roots of *Angelica Archangelica* Hoffm. (Fam. Umbelliferæ), a biennial plant indigenous to Northern Europe and Asia, and cultivated in Italy, France, Germany and elsewhere. It is collected in the autumn, sometimes cut longitudinally into slices, and dried.

The rhizome is vertical, dark brown, nearly cylindrical, from 5 to 10 centimetres in length and from 2 to 4 centimetres in diameter; the upper part bears stem-scars and the brownish, papery remains of leaves; the lower part is surrounded by numerous greyish-brown roots, which are from 20 to 30 centimetres long and from 0.5 to 1.0 centimetre thick in the upper portion, longitudinally furrowed and frequently plaited or twisted together. The fracture is short. The transversely cut surface of the rhizome shows a wide bark containing starch, radially arranged rows of oleo-resin ducts, narrow, porous, radiating wood bundles separated by wide, whitish medullary rays, and a large central pith. The root resembles the rhizome in structure, but has neither pith nor cortex. The odour is strong and aromatic, and the taste aromatic and slightly pungent.

Angelica root contains volatile oil (from 0.3 to 1 per cent.), resin (about 6 per cent.), angelic acid and a phytosterol, angelicol. The volatile oil has a specific gravity of 0.857 to 0.918; it contains phellandrene and other terpenes, together with a sesquiterpene and esters of methylethylacetic (valeric) and hydroxypentadecylic acids; the chief odorous constituent is in the portion of higher boiling-point.

Substitute.—The root of wild angelica, *A. sylvestris* Linn., a common British plant, is less branched and much less aromatic than that of *A. Archangelica* Hoffm.

Standard.—Angelica root contains not more than 5 per cent. of its stem-bases and foreign organic matter. Acid-insoluble ash, not more than 4 per cent.

Action and Uses.—Angelica root has stimulant, diaphoretic and expectorant properties, and is administered either in the form of powder, or as an infusion (1 in 20).

Dose.—0.6 to 2 grammes (10 to 30 grains).

ANILINUM

(Anilin.)

Aniline

Aniline, $\text{C}_6\text{H}_5\text{NH}_2$, may be prepared by the acid reduction of nitrobenzene. It occurs as a colourless or slightly brown, oily liquid, with a characteristic odour, and an aromatic, burning taste. Specific gravity, about 1.027. It solidifies in a freezing mixture, the crystals melting again at about -8° . Boiling-point, about 183° . With mineral acids it forms crystalline salts which are soluble in water. The addition of a drop of aniline to solution of chlorinated soda causes the formation of an intense violet colour, and the addition of a few drops of potassium dichromate solution to a mixture of aniline and sulphuric acid produces an intense blue colour. Warmed with chloroform and sodium hydroxide solution an intensely poisonous substance, carbylamine or phenyl isocyanide, is formed which has an intolerable odour. Aniline tends to become coloured on keeping and should be stored in small, well-stoppered bottles, protected from light.

Soluble in water (1 in 37) and miscible in all proportions with alcohol, ether and oils.

Action and Uses.—Aniline has many derivatives possessing valuable antipyretic and analgesic properties, but has itself no place in therapeutic medicine. Poisoning may be caused by aniline or its vapour, and absorption can occur by the mucous membrane, skin, or lungs. The oxyhæmoglobin of the blood is converted into methæmoglobin and destruction of red blood cells occurs. The clinical manifestations of poisoning are cyanosis, anæmia, muscular weakness, a subnormal

temperature and a low blood pressure. Treatment consists in the administration of stimulants and the application of warmth to the extremities. Oxygen and artificial respiration should be employed when necessary.

BENZIDINUM.—Benzidine, $(C_6H_4NH_2)_2$, is a white or slightly reddish, crystalline powder melting at about 128° . It is slightly soluble in boiling water, alcohol and ether. It is used as a reagent for the detection of certain oxidising agents.

m-PHENYLENEDIAMINA.—*m*-Phenylenediamine, $C_6H_4(NH_2)_2$, is used as a reagent for the determination of nitrites in water.

p-PHENYLENEDIAMINA.—*p*-Phenylenediamine, $C_6H_4(NH_2)_2$, and its hydrochloride are used as dyes for hair and fur. Cases of dermatitis have arisen from its use for these purposes.

PHENYLHYDRAZINÆ HYDROCHLORIDUM.—Phenylhydrazine hydrochloride, $C_6H_5NH \cdot NH_2 \cdot HCl$, is the salt of the base obtained from diazobenzene chloride by the action of stannous chloride. It occurs in thin, lustrous plates and is readily soluble in water and alcohol. Owing to its property of destroying red blood cells, phenylhydrazine hydrochloride is used in the treatment of polycythæmia and is administered by the mouth in doses of from $1\frac{1}{2}$ to 5 grains in capsules. Its action is very delayed and, therefore, difficult to control unless the red cell count and hæmoglobin are carefully watched. The red cell count may continue to fall for as long as two weeks after the last dose. As soon as any appreciable effect on the cells and hæmoglobin is noted the treatment should be interrupted until it is known how far the fall is going to continue. A rise in leucocytes is said to precede the fall in red cells. Large or too frequent doses of phenylhydrazine hydrochloride may cause severe anæmia from excessive destruction of red cells, accompanied by marked urobilinuria and jaundice. It is also used as a chemical reagent for the preparation of osazones in the identification of sugars.

ANISUM

(Anis.)

Anise

Synonyms—Aniseed; Anise Fruit.

Anise consists of the dried ripe fruits of *Pimpinella Anisum* Linn. (Fam. Umbelliferae), an annual plant, indigenous to Greece, Egypt and Asiatic Turkey and cultivated in many countries, particularly in Spain, Southern Russia and Bulgaria.

The fruit is an ovoid, somewhat laterally compressed cremocarp, about 5 millimetres long and 2 millimetres broad. The cremocarps are usually entire, with the slender pedicel attached; they are greenish-grey or brownish in colour and are rough to the touch from the presence of short, stiff hairs; the primary ridges are slender, pale, and uniform in width. A transverse section through the centre of the fruit shows, in the pericarp of each mericarp, about 30 to 50 vittæ on the dorsal surface and usually two large vittæ on the commissure; the commissural surface of the endosperm is not deeply grooved. The taste is sweet and aromatic, and the odour is characteristic.

The diagnostic **microscopical** characters are the numerous unicellular, conical, thick-walled, warty trichomes of the outer epidermis; the

narrow, branching, brown vittæ; the parallel arrangement of the narrow, tangentially elongated cells of the inner epidermis of the pericarp; the small aleurone grains, most of which contain a rosette crystal of calcium oxalate; the fixed oil of the endosperm.

Anise contains volatile oil, of which the yield is from 1.5 to 3.5 per cent.; other constituents are fixed oil, choline, sugar and mucilage. Starch and alkaloids are absent.

Varieties.—The Spanish fruits are distinguished by their large size (about 4 millimetres long), the grey or brownish-grey colour, and the tapering shape. Russian fruits are smaller, darker and more ovoid. Anise has been adulterated with fine earth and with other small seeds and fruits, such as henbane seeds and the fruits of *Conium maculatum*, *Setaria glauca* and other weed plants.

Standard.—Anise contains not more than 2 per cent. of other seeds and fruits, and not more than 1 per cent. of foreign organic matter. Acid-insoluble ash, not more than 1.5 per cent.

Anise, in powder (Pulvis Anisi : Pulv. Anis.), contains the constituents and possesses the diagnostic microscopical characters of Anisum, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Anise is a stimulating carminative and a mild expectorant. Its action depends upon the essential oil which it contains and which is generally used in preference to the fruit. Anise is used in the preparation of asthma powders and in veterinary medicines.

Preparations

Aqua Anisi Concentrata, B.P.C.—(Aq. Anis. Conc.)—Concentrated Anise Water. Oil of anise, 1 in 50. One part added to 39 parts of distilled water yields a preparation which is approximately equivalent in strength to distilled anise water, but contains 1.5 per cent. v/v of alcohol (90 per cent.). Dose.—0.3 to 1 millilitre (5 to 15 minims).

Aqua Anisi Destillata, B.P.C.—(Aq. Anis. Dest.)—Distilled Anise Water. Anise, 1 in 10. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

This water was included in the British Pharmacopœia, 1914, under the name of Aqua Anisi.

Syrupus Anisi, B.P.C.—(Syr. Anis.)—Syrup of Anise. Concentrated anise water, 1 in 8, with syrup. Dose.—2 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

ANISUM STELLATUM

(Anis. Stell.)

Star Anise

Synonyms—Star Anise Fruit; Badiane.

Star anise consists of the ripe fruits of *Illicium verum* Hook. f. (Fam. Magnoliaceæ), a tree indigenous to the Southern and South-western Provinces of China.

The fruits consist of 6 to 11, usually 8, stellately arranged carpels attached to a stout, curved pedicel. The carpels are about 12 millimetres in length, boat-shaped and bluntly-beaked at the apex, but flat

at the base. They are dark brown in colour and wrinkled; the ventral suture is often open, exposing the smooth, shining, hard, reddish-brown seed, with brittle seed coat and large, soft, oily kernel. The odour and taste are spicy and aromatic.

The diagnostic **microscopical** characters are the outer epidermis of the pericarp composed of brown, tabular cells with very thick, outer walls and a strongly striated cuticle; the palisade stone cells, with fairly large lumina, of the inner epidermis of the pericarp, from about 300 to 500 microns long; the palisade outer epidermis of the seed coat; the somewhat stellate, lignified idioblasts, about 220 microns by 145 microns, of the columella and fruit stalk; the inner epidermis of the seed coat with elongated cells, each containing several small calcium oxalate prisms; the aleurone grains, 13 to 17 microns in diameter, seldom containing crystal inclusions.

Star anise **contains** about 5 per cent. of volatile oil, found in the pericarp of the fruit and in the kernel of the seed. The fruits also contain fixed oil, resin, tannic acid and sugar, and the ash averages about 5 per cent.

Substitutes.—Japanese star anise (Shikimi), from *Illicium religiosum* Siebold, is smaller and less regular in appearance. The carpels are more wrinkled, the beak more acute and the pedicels straighter than those of *I. verum*. The fruits differ also in odour, which is balsamic, and in taste, which is disagreeably bitter instead of sweet and spicy. They contain the poisonous, crystalline principle, shikimine or sikamin. The volatile oil of *I. religiosum* differs in odour from that of *I. verum*, having a resemblance to that of cajuput, cardamom or saffrafr; it contains saffrole. The palisade cells of *I. religiosum* never exceed 400 microns in length; the idioblast stone cells, about 100 by 55 microns, are somewhat rounded, and the aleurone grains seldom reach 15 microns in diameter and usually contain from 1 to 3 crystal inclusions.

Action and Uses.—Star anise possesses properties similar to those of anise. It is used principally as a source of Oleum Anisi.

ANTHEMIS

(Anthem.)

Chamomile

Synonyms—Anthemidis Flores; Chamomile Flowers;
Roman Chamomile.

Chamomile is the dried, double or semi-double, flowerheads of cultivated varieties of *Anthemis nobilis* Linn. (Fam. Compositæ), a small annual plant indigenous to Britain and cultivated there as well as in Belgium and France. It should be **stored** in a cool, dry place to prevent attack by insects and to preserve the odour.

The dried flowerheads form hemispherical masses about 12 to 20 millimetres in diameter, white or pale buff in colour. The involucre is composed of two or three rows of oblong bracts with membranous margins and is almost entirely hidden by the reflexed outer ligulate

florets. These are pistillate, and the ligulate corolla exhibits four principal veins, three or sometimes two terminal teeth and numerous oil glands. The tubular florets are few in number and are situated towards the centre of the disc; typically, they are hermaphrodite, with a bifid stigma and an inferior ovary; in the double flowerheads, however, they frequently show malformations, such as the presence of three or four stigmas and irregularly enlarged corolla lobes. The ovary of each floret is dotted with oil glands and is devoid of a pappus. The receptacle is conical, solid and covered with numerous paleæ, which are ovate, blunt at the apex and concave, the margins being membranous. The flowers have a strong, characteristic aromatic odour and a bitter taste.

Chamomile **contains** about 0·2 per cent. of a volatile oil and the following constituents have also been isolated:—3:4-dihydroxycinnamic acid, apigenin (a trihydroxyflavone), a *d*-glycoside of apigenin, choline, *i*-inositol, triacontane, taraxasterol, phytosterolin, sugar and a mixture of fatty acids including oleic, linoleic, cerotic, stearic and palmitic. The bitter taste appears to be due to a dark-coloured amorphous material and not to any well-defined constituent; the tinctorial power of the flowers is due to the presence of apigenin.

Substitutes.—Single chamomiles, gathered from wild plants of *Anthemis nobilis*, have only one row of ligulate florets and are collected and sold in Scotland as Scotch chamomiles. The flowerheads of *Matricaria Chamomilla* Linn., the German chamomile, are sometimes supplied as single chamomiles; they may be distinguished by the naked and hollow, conical receptacle and the single row of ligulate florets. They are usually much smaller and darker in colour. Another substitute is feverfew flowers, the flowerheads of *Chrysanthemum Parthenium* Bernh., which have flat and naked receptacles.

Standard.—Chamomile contains not more than 2 per cent. of foreign organic matter. Acid-insoluble ash, not more than 1 per cent.

Action and Uses.—Preparations of chamomile are used internally to improve the appetite and aid digestion. "Chamomile tea" (1 in 20 of boiling water; dose, 1 to 4 fluid ounces) is a domestic remedy for indigestion and may be used as a vehicle for other bitters. The flowers are sometimes employed externally in the form of a poultice. Used as a fomentation, chamomile is a popular remedy in the early stages of inflammation; a decoction of chamomile and bruised poppy capsules is also used as a fomentation for dental abscesses; the decoction is applied inside the mouth and the marc is applied as a poultice. The extract may be combined in pills with purgatives to diminish the tendency to griping. Powdered chamomile is sometimes used as an ingredient of shampoo powders.

Preparations

Decoctum Papaveris et Anthemidis Forte, B.P.C.—(Dec. Papav. et Anthem. Fort.)—Strong Decoction of Poppy and Chamomile. *Syn.*—Decoctum Papaveris et Anthemidis Concentratum. Chamomile and poppy capsule, of each, 1 in 4, with alcohol and distilled water.

Extractum Anthemidis, B.P.C.—(Ext. Anthem.)—Extract of Chamomile. A soft aqueous extract containing added oil of chamomile. Dose.—0·12 to 0·5 gramme (2 to 8 grains).

Extractum Anthemidis Liquidum, B.P.C.—(Ext. Anthem. Liq.)—Liquid Extract of Chamomile. 1 in 1. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

ANTIMONII ET POTASSII TARTRAS

(Antim. et Pot. Tart.)

Potassium Antimonyltartrate

Synonyms—Antimonium Tartaratum; Tartarated Antimony; Tartar Emetic; Antimony and Potassium Tartrate.

Potassium antimonyltartrate, $\text{K}(\text{SbO})\text{C}_4\text{H}_4\text{O}_6, \frac{1}{2}\text{H}_2\text{O}$, may be prepared by setting aside a mixture of antimonious oxide and potassium acid tartrate, made into a paste with water, until combination has taken place, and then purifying by crystallisation from water. It occurs as colourless, odourless, transparent crystals, or as a white, granular powder. It has a sweet taste and effloresces on exposure to air. A less pure "tartar emetic" is prepared for use in the dyeing industry as a mordant.

Soluble in water (1 in 17), boiling water (1 in 3) and glycerin (1 in 20); insoluble in alcohol.

Standard, B.P.—Potassium antimonyltartrate contains not less than 99 per cent. of $\text{C}_4\text{H}_4\text{O}_7\text{SbK}, \frac{1}{2}\text{H}_2\text{O}$. Arsenic limit, 10 parts per million. Lead limit, 5 parts per million. It complies also with a limit test for alkalinity and acidity.

Action and Uses.—Potassium antimonyltartrate is commonly employed when it is desired to administer antimony. It is not readily dissociated and is therefore not so corrosive as the chloride, but when applied to the skin it produces redness, vesication and pustulation. Its use as a counter-irritant has been discontinued owing to the destructive action on the dermis. When administered by the mouth, it produces nausea and, in most cases, vomiting, followed by perspiration and depression. If vomiting is not produced, the gastric and intestinal mucosa may be damaged. Its use as an emetic has steadily declined. In sub-emetic doses, antimony is a reflex expectorant and is of value in the treatment of bronchitis when the mucus is tenacious.

The main therapeutic use of antimony is in the treatment of certain tropical diseases—leishmaniasis, trypanosomiasis, frambæsia, bilharziasis, and filariasis. Its trypanocidal action is probably less than that of arsenic although it has a similar action and is excreted more rapidly. In the treatment of kala-azar potassium antimonyltartrate has proved strikingly successful, converting a 90 per cent. mortality into a 90 per cent. recovery. Its action in the treatment of bilharzia is to kill both the eggs and the parent worm; it is given intravenously in 2 per cent.

w/v solution in 0.03 gramme ($\frac{1}{2}$ grain) doses, rising by 0.03 gramme ($\frac{1}{2}$ grain) at each injection to 0.12 gramme (2 grains). This dose is continued until 1.5 to 2 grammes (25 to 30 grains) has been administered. Potassium antimonyltartrate is too irritating to be given subcutaneously and is painful when given intramuscularly. It may be **administered** in aqueous mixtures in the form of Vinum Antimoniale, or in pills massed with lactose and syrup of liquid glucose. A solution for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration.

In cases of **poisoning** by antimony, persistent vomiting and diarrhœa, followed by muscular weakness and collapse, convulsions, and suppression of urine, occur. Treatment should be designed to remove the poison; the stomach should be washed out, if vomiting has not occurred, and a purge given. Tannic acid, calcium hydroxide and magnesia may be used to precipitate the antimony in the stomach. Stimulants and warmth may be needed.

Dose.—0.002 to 0.008 gramme ($\frac{1}{32}$ to $\frac{1}{8}$ grain); 0.03 to 0.06 gramme ($\frac{1}{2}$ to 1 grain), as an emetic; 0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains), by intravenous injection.

Preparation

Vinum Antimoniale, B.P.C.—(Vin. Antim.)—Antimonial Wine. Potassium antimonyltartrate, 0.4 per cent. w/v, in sherry-type wine. Dose.—0.6 to 2 millilitres (10 to 30 minims); emetic dose, 8 to 16 millilitres (2 to 4 fluid drachms).

This wine, prepared with sherry, was included in the British Pharmacopœia, 1914.

ANTIMONII ET SODII TARTRAS

(Antim. et Sod. Tart.)

Sodium Antimonyltartrate

Sodium antimonyltartrate, $\text{Na}(\text{SbO})\text{C}_4\text{H}_4\text{O}_6$, may be prepared by setting aside a mixture of antimonious oxide and sodium acid tartrate, made into a paste with water, until combination has taken place, and then purifying by crystallisation from water. It occurs as colourless, odourless, transparent, hygroscopic scales, or as powder, with a sweet taste.

Soluble in water (1 in $1\frac{1}{2}$); insoluble in alcohol.

Standard, B.P.—Sodium antimonyltartrate contains not less than 96 per cent. of $\text{C}_4\text{H}_4\text{O}_7\text{SbNa}$, calculated on the substance dried at 100° . Loss on drying at 100° , not more than 5 per cent. Lead limit, 5 parts per million. It complies also with a limit test for alkalinity and acidity.

Action and Uses.—Sodium antimonyltartrate has properties similar to those of potassium antimonyltartrate. It is less toxic and more soluble than the latter and is largely used for the treatment of bilharziasis, kala-azar, etc. It is usually **administered** intravenously, beginning with a dose of $\frac{1}{2}$ grain and increasing to 2 grains, three times a week. A solution for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration.

Dose.—0.002 to 0.008 gramme ($\frac{1}{32}$ to $\frac{1}{8}$ grain); 0.03 to 0.06 gramme ($\frac{1}{2}$ to 1 grain), as an emetic. 0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains), by intravenous injection.

ANTIMONII OXIDUM

(Antim. Oxid.)

Antimonious Oxide

Synonym—Antimony Trioxide.

Antimonious oxide may be obtained by pouring a solution of antimonious chloride into water, and decomposing the precipitated antimony oxychloride with sodium carbonate. It occurs as a greyish-white powder, fusible at a low red heat.

Insoluble in water; soluble in hydrochloric acid.

Standard.—Antimonious oxide contains not less than 99 per cent. of Sb_2O_3 . Arsenic limit, 1000 parts per million. Lead limit, 1500 parts per million. It dissolves completely when boiled with an excess of potassium acid tartrate solution.

Assay.—Dissolve about 0.25 gramme, accurately weighed, in dilute hydrochloric acid, add 5 grammes of sodium potassium tartrate and a slight excess of sodium bicarbonate, and titrate with N/10 iodine; each millilitre of N/10 iodine is equivalent to 0.007288 gramme of Sb_2O_3 .

Action and Uses.—Antimonious oxide possesses the same therapeutic properties as potassium antimonyltartrate, but in a milder degree because of its comparative insolubility. In large doses it gives rise to violent vomiting, due to its direct irritant action upon the mucous membrane of the stomach. Emesis is followed by depression and even collapse. As an expectorant and diaphoretic it is usually given in small doses, generally as Pulvis Antimonialis. A preparation similar to the latter is James' Fever Powder (Pulvis Jacobi or Pulvis Febrifugus Jacobi), which was originally prepared by calcining a mixture of equal parts of antimony sulphide and hartshorn shavings. Antimony oxide has been used in the treatment of leishmaniasis and trypanosomiasis in the form of an injection, equal parts of glycerin and distilled water being used as solvent. Doses of the injection equivalent to $\frac{1}{160}$ to $\frac{1}{50}$ grain of antimonious oxide are given subcutaneously or intravenously for this purpose.

Dose.—0.06 to 0.12 gramme (1 to 2 grains).

Preparation

Pulvis Antimonialis, B.P.C.—(Pulv. Antim.)—Antimonial Powder. Antimonious oxide, 1 in 3, with calcium phosphate. Dose.—0·2 to 0·4 gramme (3 to 6 grains).

This powder was included in the British Pharmacopœia, 1914.

ANTIMONIUM SULPHURATUM

(Antim. Sulphur.)

Sulphurated Antimony

Synonym—Crocus Antimony; Kermes Minerale.

Sulphurated antimony may be prepared by the following process.—Dissolve 25 parts of sodium hydroxide in 500 parts of distilled water, add 50 parts of purified black antimony and 50 parts of sublimed sulphur, boil for two hours, stirring frequently and occasionally adding distilled water to replace that lost by evaporation; while the mixture is still hot, add 900 parts of boiling distilled water, strain through calico and gradually add dilute sulphuric acid in slight excess. Finally, collect and wash the precipitate on a calico filter until the filtrate shows no trace of sulphates, and dry the sulphurated antimony at a temperature not exceeding 100°. The product contains antimony sulphides, antimony oxides and free sulphur. It occurs as an amorphous, orange-red powder, without taste or odour.

Insoluble in water; readily and almost completely soluble in sodium hydroxide solution.

Standard.—Sulphurated antimony contains antimony compounds equivalent to not less than 43 per cent. and not more than 50 per cent. of Sb. Arsenic limit, 1000 parts per million.

Assay.—Weigh accurately about 0·25 gramme, add 10 millilitres of hydrochloric acid and a few drops of bromine, and heat until dissolved; to the solution add 10 millilitres of sulphurous acid, warm for a short time and then boil off the excess of sulphur dioxide; titrate with N/10 potassium bromate using methyl orange as indicator; each millilitre of N/10 potassium bromate is equivalent to 0·006088 gramme of Sb.

Action and Uses.—Sulphurated antimony is a diaphoretic and emetic, but owing to the uncertainty of its action it is now rarely prescribed. It is occasionally employed for gout and rheumatism in the form of *Pilulæ Hydrargyri Subchloridi Compositæ*.

Dose.—0·06 to 0·12 gramme (1 to 2 grains).

ANTIMONIUM NIGRUM PURIFICATUM.—Purified black antimony, Sb_2S_3 , is the natural substance freed from siliceous matter and arsenic by fusion and subsequent digestion of the powdered sulphide with ammonia. It occurs as a nearly black, crystalline powder which is insoluble in water, but almost entirely soluble in hot hydrochloric acid with evolution of hydrogen sulphide.

Preparation

Pilulæ Hydrargyri Subchloridi Compositæ, B.P.C.—(Pil. Hydrarg. Subchlor. Co.)—Compound Mercurous Chloride Pills. *Syn.*—Compound Calomel Pills; Plummer's Pills. Each pill contains 1 grain of mercurous chloride, 1 grain of sulphurated antimony and 2 grains of guaiacum resin. Dose.—1 or 2 pills.

The mass with which these pills are made was included in the British Pharmacopæia, 1914, under the name of Pilula Hydrargyri Subchloridi Composita.

ANTITOXINUM DIPHThERICUM

(Antitox. Diphtheric.)

Diphtheria Antitoxin

Diphtheria antitoxin consists of the serum of animals, or a preparation of the serum, containing the globulins which have the specific power of neutralising the toxin formed by *Corynebacterium diphtheriæ*. The animals are immunised by the injection of gradually increasing doses of a sterile filtrate from a liquid culture of *C. diphtheriæ*. When a satisfactory degree of immunisation has been effected, a quantity of blood is withdrawn, allowed to clot and the serum collected. It may be used in the liquid form, or may be dried. The antitoxic globulins may be separated from the serum by fractional precipitation and the precipitate may be used in solution or dried. Both liquid forms may contain an antiseptic.

The serum occurs as a yellow or yellowish-brown liquid or, in the solid condition, as a yellowish-white powder, or yellow or yellowish-brown flakes. The solution of the antitoxic globulins is of a yellowish-brown or greenish-yellow colour. Both liquid forms are transparent when first made, but become faintly opalescent when stored; they are almost odourless except for any odour due to an added antiseptic. The solution of the antitoxic globulins does not contain more than 1 gramme of solid matter for each 5000 units and the liquid serum does not contain more than 10 per cent. w/v of solid matter. The dried antitoxic globulins resembles the dried serum in appearance and 10 per cent. w/v solutions of the dried forms resemble the liquid forms. The solid forms do not contain any added antiseptic or other substance.

In whatever form the product is obtained it should be **stored** in sterilised glass containers, sealed so as to exclude bacteria, and kept at as low a temperature above its freezing-point as possible. It deteriorates rapidly during the first few months after it is prepared; the subsequent rate of deterioration, when stored at temperatures not above 10°, is usually about 5 per cent. per annum and does not exceed 10 per cent. When stored at higher temperatures the rate of deterioration is greater and at temperatures from 15° to 20°, it may be up to 20 per cent. per annum. The number of units in each container is sufficient to ensure that the number stated on the label is still present at the end of the period during which the preparation is intended to be used. The

label on the container or the package states the nature of the contents and the date after which it is not intended to be used. This label also states the minimum total number of units in the container and also the number of units in one millilitre or in one gramme, or the total number of millilitres of liquid or grammes of dried product, in the container.

Standard, B.P.—All forms of diphtheria antitoxin comply with the tests for sterility and with tests for freedom from abnormal toxicity prescribed by the regulations made under the Therapeutic Substances Act, 1925. Liquid preparations have a potency of not less than 400 units per millilitre; solid preparations have a potency of not less than 4000 units per gramme.

Action and Uses.—Diphtheria antitoxin neutralises the toxin elaborated by *C. diphtheriæ* locally at the seat of the disease, but does not affect the vitality of the infecting organisms. Pathological changes already induced by the toxin are not affected by antitoxin. The dose of diphtheria antitoxin varies according to the severity and stage of the disease, not with the age of the patient. Local measures of disinfection are also used with the object of destroying streptococci and other organisms, since diphtheria is never a simple infection, and to lessen the danger of infection to others.

For curative purposes at least 8000 units in mild cases treated early, up to 12,000 units in serious cases, or 20,000 units in severe cases treated at a later stage, should be given intramuscularly, or intravenously in case of urgency. If no improvement results in twenty-four hours, the same doses, or larger, should be repeated. A single initial large dose is more effective than when the dose is divided between two injections on successive days. Children require at least as large a dose as adults. Intramuscular injection is preferable to subcutaneous since it secures more rapid absorption. The maximum concentration of antitoxin in the blood is not reached until about three days after subcutaneous injection, but is reached about twenty-four hours after intramuscular injection. Intravenous injection has the advantage that maximum concentration of antitoxin in the blood occurs immediately, and this mode of injection is usually adopted for malignant or severely toxic cases. For such cases, doses ranging from 70,000 to 200,000 units or even more, given partly intravenously and partly intramuscularly, may be necessary to effect a cure. The addition of *Liquor Adrenalinæ Hydrochloridi* in doses of 0·25 to 0·5 millilitre (4 to 8 minims) to serum injected intravenously is sometimes adopted as a preventive of anaphylaxis or allergic reactions. For prophylactic purposes, 500 to 1000 units may be injected subcutaneously for the temporary immunisation of contacts; such immunity is of short duration and probably does not persist longer than two or three weeks. Subcutaneous injections are usually made in the flank or between the shoulders, intravenous injections into a vein of the hand or arm.

Dose.—Prophylactic, 500 to 1000 units, by injection; therapeutic, 10,000 to 20,000 units, by injection.

ANTITOXINUM SCARLATINUM

(Antitox. Scarlatin.)

Streptococcus Antitoxin (scarlatina)*Synonym*.—Scarlet Fever Streptococcus Antitoxin.

Streptococcus antitoxin (scarlatina) consists of a solution of the globulins obtained from the serum of horses which have been immunised by the injection of live cultures of *Streptococcus hæmolyticus scarlatinae* (as in the method originally used by Dochez), or of the toxin from this micro-organism (as in the method used by G. F. and G. H. Dick), or by a modification of these methods. A potent toxin can be prepared as described under Toxinum Scarlatinum. When living streptococci are injected, the specific stimulus is provided by toxin produced *in vivo*. After a satisfactory degree of immunisation has been effected, a quantity of blood is withdrawn from the jugular vein under aseptic conditions and is allowed to clot. The clear serum is decanted and the globulins separated by fractional precipitation. The globulins are purified by dialysis and redissolved in normal saline solution containing 0.5 per cent. of phenol or 0.3 per cent. of cresol as a preservative.

Streptococcus antitoxin (scarlatina) should be **stored** between 5° and 15°. Under these conditions it will retain its potency for several years. It should be issued in sterilised containers sealed so as to exclude bacteria. If the containers permit the withdrawal of less than the entire contents, the antitoxin should contain a preservative at least as effective as 0.5 per cent. of phenol. The label of the container should indicate the date after which the antitoxin is not intended to be used.

Standard.— Streptococcus antitoxin (scarlatina) is a pale, yellowish-grey liquid. It shows not more than a slight opalescence or precipitate and yields not more than 20 per cent. of total solids. It conforms to the tests for sterility and for freedom from abnormal toxicity prescribed by the regulations made under the Therapeutic Substances Act, 1925. Standardisation of the antitoxin is a matter of considerable difficulty, the available methods being the skin neutralisation, Schultz-Charlton, and passive immunity tests on the human subject, the Parish-Okell test on rabbits and the Wadsworth-Kirkbride test on goats. Although it has been possible by the use of one or other of these to ensure a high antitoxin content, none of the methods has yet met with international acceptance. The Parish-Okell rabbit method (determining the quantity of antitoxin which will neutralise a culture of streptococcus or a dose of toxin given intravenously) and the skin neutralisation test on human subjects (determining the quantity of antitoxin which will neutralise a known amount of toxin in Dick tests) are the methods more generally employed. On the basis of the skin neutralisation test, American workers have established a unit as the smallest amount of antitoxin which is required to neutralise 50 skin-test doses of scarlet

fever toxin. Because of the difficulties of the assay, it is not universally accepted that dosage can be stated usefully in terms of this unit.

Action and Uses.—*Streptococcus antitoxin* (scarlatina) is used for the diagnosis and treatment of scarlet fever, and for conferring passive immunity on contacts. In the investigation of a case of suspected scarlet fever, when the rash is less than seventy hours old, the Schultze-Charlton or blanching test is often of decisive value in differentiating the rash of scarlet fever from that of other eruptive fevers. The antitoxin may be used undiluted, but usually 0.2 millilitre of a 1 in 10 to 1 in 100 dilution of the antitoxin is injected intradermally when the eruption is marked. If the rash is that of scarlet fever a positive reaction, denoted by a blanching of the skin from 10 to 40 millimetres in diameter, will occur in from four to ten hours and persist for the duration of the eruption. This is due to the specific local effect of the antitoxin on the toxin.

In treatment, the antitoxin should be administered as soon as possible after diagnosis has been made. If given early, it has an immediate and favourable influence on the specific toxæmia of scarlet fever, reducing temperature, malaise and rash, and, according to some clinicians, the incidence of complications. Antitoxin is of little value when adenitis, middle ear disease, etc., have set in. The period of detention in hospital of patients who have received serum early in the disease is usually shortened. Passive immunisation has been found of value in the general wards of childrens' hospitals and in institutions and schools. The contacts are examined by the Dick test, and the positive reactors protected as soon as possible with *streptococcus antitoxin* (scarlatina).

Some workers believe that all the hæmolytic streptococci of human origin represent one species of bacteria with common pathogenic potentialities, and that hæmolytic streptococci from sources other than scarlet fever produce the same toxin, though to a less degree. *Streptococcus antitoxin* (scarlatina) has, therefore, been used in the treatment of septicæmia, erysipelas, acute tonsillitis and acute streptococcal infections in general in place of antitoxic sera prepared from the homologous strains. Its use has been recommended also in the prophylactic treatment of wounds received while performing post-mortem examinations or surgical operations on septic cases.

Dose.—Prophylactic, 5 to 10 millilitres to Dick-positive contacts to confer a passive immunity lasting 10 to 14 days; therapeutic, for mild cases, at least 10 millilitres, for severe and toxic cases, 20 to 60 millilitres given as early as possible, and repeated daily in severe cases; intramuscularly in moderate or mild cases.

ANTITOXINUM TETANICUM

(Antitox. Tetanic.)

Tetanus Antitoxin

Tetanus antitoxin consists of the serum of animals, or a preparation of the serum, containing the globulins which have the specific power of

neutralising the toxin formed by *Bacillus Tetani*. The animals are immunised by the injection of gradually increasing doses of a sterile filtrate from a liquid culture of *B. Tetani*. When a satisfactory degree of immunisation has been effected, a quantity of blood is withdrawn, allowed to clot and the serum collected. It may be used in the liquid form, or may be dried. The antitoxic globulins may be separated from the serum by fractional precipitation and the precipitate may be used in solution, or may be dried. Both liquid forms may contain an antiseptic.

The serum occurs as a yellow or yellowish-brown liquid or, in the solid condition, as a yellowish-white powder, or yellow or yellowish-brown flakes. The solution of the antitoxic globulins is of a yellowish-brown or greenish-yellow colour. Both liquid forms are transparent when first made, but become faintly opalescent when stored; they are almost odourless except for any odour due to an added antiseptic. The solution of the antitoxic globulins does not contain more than 1 gramme of solid matter for each 6000 units, and the serum does not contain more than 10 per cent. w/v of solid matter. The dried antitoxic globulins resembles the dried serum in appearance and 10 per cent. w/v solutions of the dried forms resemble the liquid forms. The solid forms do not contain any added antiseptic or other substance.

In whatever form the product is obtained it should be **stored** in sterilised glass containers, sealed so as to exclude bacteria, and kept at as low a temperature above its freezing-point as possible. The number of units in each container must be sufficient to ensure that the number stated on the label is still present at the end of the period during which the preparation is intended to be used. The label on the container or the package states the nature of the contents, whether for prophylactic or therapeutic use, and the date after which the preparation is not intended to be used. The label on the container states the total number of International units in the container and the equivalent number of the units adopted in the United States Pharmacopœia X, which is one half the number of International units. It also states either the number of International units in 1 millilitre or 1 gramme, or the number of millilitres of liquid or grammes of solid in the container.

Standard, B.P.—All forms of tetanus antitoxin comply with the tests for sterility and with the tests for abnormal toxicity prescribed by the regulations made under the 'Therapeutic Substances Act, 1925. For prophylactic use, liquid preparations have a potency of not less than 300 units per millilitre and solid preparations of not less than 3000 units per gramme. For therapeutic use, liquid preparations have a potency of not less than 1600 units per millilitre and solid preparations of not less than 16,000 units per gramme.

Action and Uses.—Tetanus antitoxin is truly antitoxic, that is, it neutralises the toxin of the tetanus bacillus, rendering it inert. Its neutralising power is most marked *in vitro*; as a curative agent in acute tetanus its action is somewhat disappointing, owing to the fact that the

tetanus poison has so extraordinary an affinity for nerve cells that a considerable concentration of antitoxin is required subsequently to overcome it. Also it is not until the action of the toxin upon nerve tissue is exerted that symptoms of tetanus arise; as in the case of diphtheria, the antitoxin can destroy the toxin, but will not influence pathological tissue changes already produced.

The early treatment of tetanus being of supreme importance, the antitoxin is of greatest use as a prophylactic. It does not immunise for more than three weeks and, since the incubation period of tetanus may be as long as one month, 1000 units should be injected immediately after all wounds, when there is any likelihood of tetanus ensuing, 1000 units a fortnight afterwards, and a third injection in another fortnight. Sometimes a mixture of tetanus antitoxin and gas-gangrene antitoxin (*perfringens*) is employed prophylactically after wounds which may have been infected by both organisms. Dried tetanus antitoxin has been recommended as a dressing for wounds, as well as for preparing a solution for injection. For curative effect, the antitoxin should be injected as soon as the diagnosis is probable; 20,000 units should be given, partly intraspinally and partly intravenously, the part doses being repeated on two successive days if necessary. The intravenous dose should be repeated at least once in the next forty-eight hours and the intraspinal injection should be repeated daily at first, and at longer intervals as the patient improves.

Dose.—Prophylactic, 1000 to 2000 units, by injection; therapeutic, 20,000 to 40,000 units, by injection.

ANTITOXINUM WELCHICUM

(Antitox. Welchic.)

Gas-gangrene Antitoxin (*perfringens*)

Gas-gangrene antitoxin (*perfringens*) consists of the serum of animals, or a preparation of the serum, containing the globulins which have the specific power of neutralising the toxin formed by *Bacillus perfringens* (*B. Welchii*). The animals are immunised by the injection of gradually increasing doses of a sterile filtrate from a liquid culture of *B. perfringens* (*B. Welchii*). When a satisfactory degree of immunisation has been effected, a quantity of blood is withdrawn, allowed to clot, and the serum collected. It may be used in the liquid form, or may be dried. The antitoxic globulins may be separated from the serum by fractional precipitation and the precipitate may be used in solution, or may be dried. Both liquid forms may contain an antiseptic.

The serum occurs as a yellow or yellowish-brown liquid or, in the solid condition, as a yellowish-white powder, or yellowish-brown flakes.

The solution of the antitoxic globulins is of a yellowish-brown or greenish-yellow colour. Both liquid forms are transparent when first made, but become faintly opalescent when stored; they are almost odourless except for any odour due to an added antiseptic. The solution of the antitoxic globulins does not contain more than 20 per cent. w/v of solid matter and the liquid serum does not contain more than 10 per cent. w/v of solid matter. The dried antitoxic globulins resembles the dried serum in appearance, and 10 per cent. w/v solutions of the dried forms resemble the liquid forms. The solid forms do not contain any added antiseptic or other substance.

In whatever form the product is obtained it should be **stored** in sterilised glass containers sealed so as to exclude bacteria, and kept at as low a temperature above its freezing-point as possible. The label on the container or the package states the nature of the contents and the date after which it is not intended to be used. The label on the container states the minimum total number of units in the container, also the number of units in one millilitre or in one gramme, or the total number of millilitres of a liquid or grammes of dried product in the container. The number of units placed in each container must be sufficient to ensure that the number stated on the label is still present at the end of the period during which the preparation is intended to be used.

Standard, B.P.—All forms of gas-gangrene antitoxin (*perfringens*) comply with the tests for sterility and with tests for freedom from abnormal toxicity prescribed by the regulations made under the Therapeutic Substances Act, 1925.

Action and Uses.—Gas-gangrene antitoxin is used in cases of acute intestinal obstruction and of peritonitis with paralytic ileus. It is also used as a prophylactic measure against the development of gas-gangrene after injury. The therapeutic dose is from 10,000 to 20,000 units, given intravenously, followed by daily intramuscular injections of 4000 to 10,000 units. Prophylactic injections of 4000 units are given before operation in cases of acute obstruction. From 500 to 1000 units appear sufficient when given prophylactically immediately after injury. This dose may be given with tetanus antitoxin and preferably with the other gas-gangrene antitoxins.

Dose.—Prophylactic, 4000 units, by injection; therapeutic, 10,000 to 20,000 units, by intravenous injection.

OTHER GAS-GANGRENE ANTITOXINS.—Gas-gangrene may be caused by organisms other than *B. perfringens*, and sera are prepared by immunising horses against the toxins produced by *B. oedematis maligni* (*Vibrio septique*) and *B. novyi* (*B. oedematis*). The toxins are produced by a method similar to that employed in the production of *B. perfringens* toxin. *V. septique* antitoxin is tested by intravenous injection, and *B. oedematis* antitoxin by intramuscular injection into mice, or both antitoxins by intracutaneous injection into guinea-pigs. There is no official unit for these antitoxins, their potency being recorded in terms of provisional units representing the neutralising power of an arbitrarily chosen volume of a selected serum.

APIOL**(Apiol)****Apiol**

Apiol is prepared by extracting the dried fruit of parsley, *Carum Petroselinum* Benth. et Hook. (Fam. Umbelliferae), with alcohol, distilling off the solvent, cooling to permit the deposition of amorphous solid residue, apiin, from which the apiol is then decanted. It is a green, oily liquid having a peculiar odour and a disagreeable, acrid taste. Its specific gravity is from 1.055 to 1.091.

Insoluble in water.

Action and Uses.—Apiol is used chiefly in dysmenorrhœa and amenorrhœa, and also as a diuretic. In large doses apiol sometimes produces effects similar to those of cinchonism, such as ringing in the ears, headache and vertigo. It is usually **administered** in capsules.

Dose.—0.2 to 0.6 millilitre (3 to 10 minims).

"GREEN APIOL" is a commercial liquid apiol, prepared by extracting dried parsley fruit with ether, distilling off most of the solvent at a low temperature, and removing final traces by exposure to warm air. It is a light green liquid, having an odour of parsley, and is distinguished from apiol by its lower specific gravity of about 0.93.

YELLOW LIQUID APIOL is a thick, oily liquid, yellowish-brown in colour. It is prepared by purifying "green apiol."

APIOLE, OR CRYSTALLINE APIOL, $C_{12}H_{11}O_4$, occurs in the form of white acicular crystals, having a persistent parsley odour and a burning taste. It is slightly soluble in water, freely soluble in chloroform, ether and alcohol, from which it can be easily crystallised. It dissolves in sulphuric acid with a characteristic blood-red colour. Melting-point, 29° to 30° . It combines with bromine to form tribromopiole, melting-point, 110° .

DILL-APIOLE, $C_{12}H_{14}O_4$, is an oily, non-crystallisable liquid obtained from volatile oil of Indian dill fruit, *Anethum Sowa* Roxb. It is isomeric with apiole. Its specific gravity is about 1.15 and it has poisonous properties.

APIUM**(Apium)****Celery**

Synonyms—Apium Fructus; Celery Fruit; Celery Seed.

Celery consists of the dried, ripe fruits of cultivated plants of *Apium graveolens* Linn. (Fam. Umbelliferae), a biennial herb indigenous to Southern European countries, and found also in India and the United States of America. The plant grows wild in marshy places, especially near the sea, and has a rank odour and disagreeable taste, which have disappeared from the cultivated variety.

The fruit is a cremocarp, 1.0 to 1.5 millimetres long, about 1.5 millimetres wide and 0.5 millimetre thick, sub-spherical and laterally compressed, having two small stylopods and an occasional, slender, straight pedicel. The mericarps are mostly separate, somewhat crescent-shaped, glabrous, dark brown, with five paler brown, straight ridges and the commissural surface nearly flat. A transverse section through the centre of a mericarp is almost pentagonal; it shows a brown pericarp in which are 6 to 9 oval vittæ, 2 within the commissural surface and usually 1, sometimes 2 or 3, in each groove of the dorsal surface; the endosperm is dense and oily, and a minute embryo occurs near the apex. The odour is aromatic and characteristic, and the taste aromatic and slightly camphoraceous.

The diagnostic **microscopical** characters of the fruit are the polygonal epidermal cells, with slightly wavy side walls and the outer walls radiately striated and frequently papillose; the conspicuous endocarp tissue of narrow, brown, thin-walled, lignified, tangentially arranged cells; the brown vittæ, with a secretory epithelium and transverse walls at intervals; the large proportion of endosperm tissue composed of thick-walled polygonal cells containing fixed oil and aleurone grains, each of which encloses a rosette crystal of calcium oxalate.

Celery **contains** volatile oil of which it yields from 2 to 3 per cent. The oil possesses the characteristic odour of the drug and consists mainly of terpenes, but its odour is due to a ketoacid, sedanonic acid, present as an anhydride, and a hydroxyacid, sedanolic acid, which is present as its lactone, sedanolid; pinene is absent. The oil also contains palmitic acid and two phenols, one of which is guaiacol. Sarch and alkaloids are absent. The ash averages about 10 per cent.

Standard.—Celery contains not more than 4 per cent. of other seeds and fruits, and not more than 1 per cent. of other foreign organic matter. Acid-insoluble ash, not more than 2 per cent.

Celery, in powder (*Pulvis Apii* : *Pulv. Apii*), contains the constituents and possesses the diagnostic microscopical characters of *Apium*, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Celery is reported to have a sedative and tonic effect upon the nervous system, and, as a decoction, is a popular domestic remedy for the treatment of rheumatism. It is doubtful, however, whether it has any real therapeutic value. The oil is sometimes prescribed as an antispasmodic and nerve stimulant in doses of $\frac{1}{2}$ to 3 minims and in rheumatoid arthritis in doses of 5 to 15 minims.

Dose.—1.2 to 4 grammes (20 to 60 grains).

Preparation

Extractum Apii Liquidum, B.P.C.—(*Ext. Apii Liq.*)—Liquid Extract of Celery. 1 in 1. Dose.—0.3 to 1.2 millilitres (5 to 20 minims).

APOCYNUM

(Apocyn.)

Apocynum*Synonym*—Canadian Hemp.

Apocynum consists of the rhizome and root of *Apocynum cannabinum* Linn. (Fam. Apocynaceæ), and of other species of *Apocynum*, herbaceous perennials, growing in the United States of America and Canada.

The drug occurs in cylindrical, simple or branched, sometimes tortuous pieces about 2.5 to 10 centimetres long and 4 to 14 millimetres in diameter, grey or brownish-grey, longitudinally wrinkled and transversely fissured, some pieces bearing scars of rootlets. The fracture is short. The smoothed, transversely cut surface exhibits a brownish cortex, and a large, yellowish-white, porous wood. Pith is present in pieces of the rhizome. Laticiferous tissue, present in the pith and cortex, is visible with a lens as small brown specks, and the parenchymatous cells of the pith, cortex and medullary rays are filled with numerous starch grains of varying shapes from 5 to 17 microns in diameter, some of which are compound, consisting of 2 or 3 components. It is inodorous, but has a disagreeable, very bitter taste.

Apocynum **contains** the glycoside, cymarín, to which its physiological action is due, and apocynin (acetovanillone). Cymarín on hydrolysis with cold hydrochloric acid yields cymarose and cymarigenin; the latter is identical with strophanthidin and with apocynamarín from *A. androsæmifolium* Linn.

Substitute.—The rhizome and root of *Apocynum androsæmifolium* Linn. somewhat resemble Apocynum, but are distinguished by the presence of small groups of stone cells in the bark.

Standard.—Apocynum contains not more than 5 per cent. of stems and other foreign organic matter.

Action and Uses.—Apocynum belongs to the group of cardiac tonics and has an action resembling, in the main, that of digitalis. It differs from digitalis, however, in that it is more irritant to the gastrointestinal tract, and in large doses may cause gastric ulcerations. It has been used as a diuretic in cardiac dropsy. It has no direct action on the kidneys, but increases the efficiency of the heart. On account of its irritant action, apocynum should be used with caution and it should not be prescribed in acute conditions or when there is inflammation of the stomach or intestines. It may be **administered** as the tincture.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

Preparation

Tinctura Apocyni, B.P.C.—(Tinct. Apocyn.)—Tincture of Apocynum. *Syn.*—Tincture of Canadian Hemp. 1 in 10. **Dose.**—0.3 to 0.6 millilitre (5 to 10 minims).

APOMORPHINÆ HYDROCHLORIDUM

(Apomorph. Hydrochlor.)

Apomorphine Hydrochloride

Apomorphine hydrochloride may be obtained by heating morphine with hydrochloric acid under pressure. It occurs as a greyish-white, glistening, microcrystalline powder which becomes green on exposure to air and light. The aqueous solution is neutral to litmus and colourless, but becomes green on exposure to air and light, the change being retarded by the addition of dilute hydrochloric acid. A dilute aqueous solution yields, on the addition of sodium bicarbonate solution, a precipitate which is white at first, becoming green; the precipitate is soluble in many organic solvents, giving with alcohol (90 per cent.) a green solution, with chloroform a blue solution, and with ether a purple solution. The precipitate obtained on the addition of silver nitrate solution to an aqueous solution of apomorphine hydrochloride darkens rapidly. Apomorphine hydrochloride should be **stored** in a well-closed container and protected from light; solutions decompose readily.

Soluble in water (1 in 50) and alcohol (1 in 50); slightly soluble in chloroform and ether.

Standard, B.P.—Apomorphine hydrochloride loses, when dried at 100°, not more than 5 per cent. of its weight. Ash, not more than 0.1 per cent. It complies also with a limit test for decomposition products.

♂ **Action and Uses.**—Apomorphine differs from morphine in that it has a stimulant action on the medulla and is employed almost entirely to produce emesis. If injected hypodermically, 0.006 gramme ($\frac{1}{16}$ grain) will produce vomiting in a few minutes; taken by the mouth, the same dose would act merely as an expectorant and diaphoretic, increasing and rendering less tenacious the bronchial mucus. It also differs from morphine in that it increases oxidation and tissue breakdown, whilst morphine diminishes them. Apomorphine resembles morphine in depressing sensory nerve cells in the brain and so relieving pain. Small non-emetic doses are injected hypodermically as a sedative in alcoholic excitement and delirium tremens.

Apomorphine hydrochloride is **administered** in the form of Syrupus Apomorphinæ for its action as an expectorant. It is an ingredient of some diamorphine preparations and is added for its expectorant action; its emetic property prevents the abuse of such preparations by addicts. Apomorphine hydrochloride is **incompatible** with alkaline substances. Apomorphine and its salts should be examined immediately before use, and the hydrochloride rejected if an emerald-green colour is produced when 1 part is shaken with 100 parts of water. Injectio Apomorphinæ Hypodermica, containing 1 per cent. w/v of the salt and 1 per cent. v/v of dilute hydrochloric acid in recently boiled and cooled distilled water, was included in the British Pharmacopæia, 1914, and was administered in doses of 5 to 10 minims. A solution for **injection** may be sterilised by

tyndallisation or by filtration and, if kept, should be stored in containers, protected from light, which comply with the tests for the limit of alkalinity of glass.

Dose.—Expectorant, 0.001 to 0.002 gramme ($\frac{1}{100}$ to $\frac{1}{50}$ grain); emetic or hypnotic, 0.002 to 0.008 gramme ($\frac{1}{50}$ to $\frac{1}{10}$ grain), by subcutaneous injection.

Preparation

Syrupus Apomorphinæ, B.P.C.—(Syr. Apomorph.)—Syrup of Apomorphine. Each fluid drachm contains $\frac{1}{10}$ grain of apomorphine hydrochloride with dilute hydrochloric acid, alcohol (90 per cent.), distilled water and syrup. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

AQUA DESTILLATA

(Aq. Dest.)

Distilled Water

H₂O = 18.016

Distilled water is prepared by the distillation of potable water. It is a clear, colourless, tasteless and odourless liquid.

Standard, B.P.—Distilled water yields, on evaporation to dryness on a water-bath, not more than 0.001 per cent. w/v of residue. It complies with limit tests for sulphate, chloride, lead, copper, iron, ammonia and oxidisable matter.

Action and Uses.—Distilled water is used as a solvent. For the preparation of solutions for administration by injection, and also for eye lotions, it is necessary to use sterilised water (Aqua Sterilisata) owing to the bacterial contamination of ordinary distilled water. Intravenous injections should be prepared with sterilised redistilled water which is not more than twenty-four hours old (sterilised water for intravenous injections); for other purposes sterilised water should be used within a month of its distillation. Distilled water, twice redistilled from glass vessels and then sterilised, is sometimes used for the preparation of intravenous injections and certain biological preparations. Intravenous and subcutaneous injections of large quantities of normal saline or other sterile solutions, prepared with distilled water, may cause a rise in temperature and systemic disturbance.

Preparation

Aqua Sterilisata, B.P.—(Aq. Steril.)—Sterilised Water. Distilled water collected in glass receivers, transferred to hard glass containers which are closed so as to exclude bacteria, and sterilised by heating in an autoclave or by boiling for thirty minutes. It must be used within one month of its preparation. Sterilised water for intravenous injections is distilled water redistilled in chemically clean apparatus, the first part of the distillate being rejected and the remainder collected in sterilised hard glass containers which are sealed and sterilised by heating in an autoclave or by boiling for thirty minutes; it must be used within twenty-four hours of its preparation.

ARARоба

(Ararob.)

Araroba*Synonyms*—Crude Chrysarobin; Goa Powder.

Araroba is the substance found in cavities in the trunk of *Andira Araroba* Aguiar (Fam. Leguminosæ), a large tree growing in the damp forests of Bahia, Brazil. It is scraped out of the cavities together with woody debris and is exported in a crude and moist condition as a coarse, amber-brown powder, containing numerous fragments of wood. This material is dried and powdered.

It occurs as a brownish-yellow to dark brown powder. When 1 milligram of benzene extract is mixed on a white tile with a drop of fuming nitric acid, and one drop of dilute solution of ammonia carefully added, a brilliant evanescent, blue-violet colour, which rapidly becomes dull reddish-violet, is produced at the line of contact. **Microscopically**, the powder shows the presence of numerous, minute, yellow, prismatic crystals, and granular, amorphous particles accompanied by fragments of woody tissue.

Araroba **contains** chrysophanolanthranol, the monomethylether of dehydroemodinanthranol, chrysophanol (chrysophanic acid), with smaller amounts of ararobinol, emodinmonomethylether, the anthranol of emodinmonomethylether and traces of emodin.

Standard.—Araroba yields to hot benzene not less than 50 per cent. of extractive.

Action and Uses.—The action of araroba depends on the presence of chrysarobin. It may be applied **externally** in the form of an ointment, 1 in 16, in lard, as a stimulant and parasiticide in psoriasis, acne rosacea and ringworm. The preparation should be diluted with an equal quantity of lard when it is to be used on a tender skin.

ARECA

(Arec.)

Areca*Synonyms*—Arecæ Semina; Areca Nuts; Betel Nuts.

Areca consists of the dried, ripe seeds of *Areca Catechu* Linn. (Fam. Palmae), a palm cultivated in tropical India, in the Philippines and in the East Indian Islands.

The seeds have the shape of a short, rounded cone and are about 20 to 27 millimetres long and 22 to 25 millimetres wide. The surface is brownish and is marked with a network of pale, depressed lines running chiefly from the hilum, which is situated at the base. The seeds are very hard and a transverse section exhibits a ruminate endosperm, the dark folds of the seed coats ramifying throughout the white endosperm;

they have no characteristic odour, but possess an astringent, bitter taste.

The diagnostic **microscopical** characters are the cells of the endosperm with thick, colourless, cellulosic walls, perforated by large, circular, simple pits and containing small amounts of protein and oil; the sclerenchymatous cells of the seed coats with moderately thick, lignified and pitted walls; the cells of the ruminations, which have thin, pitted walls and dark reddish-brown contents; the thick-walled, fibrous cells from the funicle.

Areca **contains** the liquid, volatile alkaloid, arecoline, $C_8H_{13}O_2N$, which forms crystalline salts. Other alkaloids present are guvacine (1 : 2 : 5 : 6-tetrahydropyridine-3-carboxylic acid), guvacoline, the methyl ester of guvacine, arecaidine (arecaine), its N-methyl derivative, and arecolidine. Arecoline is the methyl ester of arecaidine. The drug also contains about 15 per cent. of a red, amorphous tannin and about 14 per cent. of fat, together with resin and mucilage.

Areca in powder (*Pulvis Arecæ* : *Pulv. Arec.*), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—Areca is mildly astringent and is used chiefly in veterinary practice as a vermifuge for tape-worm. It is **administered** in the form of powder, or mixed with honey, syrup, or butter. In tropical countries areca is used as a masticatory.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

ARECOLINÆ HYDROBROMIDUM.—Arecoline hydrobromide, $C_8H_{13}O_2N$, HBr, occurs as fine, white, stable, needle-shaped crystals, easily soluble in water and alcohol, and soluble with difficulty in ether and chloroform. It melts at about 170° . Arecoline has an action very similar to that of pilocarpine. It excites the cranio-sacral autonomic nerve-endings. There is thus increased tonus and automatic movements in most plain muscle throughout the body. The muscles chiefly affected are those of the alimentary canal, uterus and bronchioles; it also causes constriction of the pupil and slowing of the heart. It is a powerful sialagogue. The action of arecoline is completely antagonised by atropine. Arecoline hydrobromide is employed by hypodermic injection in veterinary practice as a cathartic in the treatment of impaction of the colon and similar conditions. The dose for horses is $\frac{1}{2}$ to $1\frac{1}{2}$ grains. It is given orally as a tannicide to dogs in doses of $\frac{1}{16}$ to $\frac{1}{2}$ grain after a preliminary period of fasting. A 1 per cent. solution has been suggested for reducing intra-ocular tension in glaucoma; it is irritating to the conjunctiva and its myotic effect is of short duration.

ARGENTI NITRAS

(Argent. Nit.)

Silver Nitrate

Silver nitrate may be prepared by dissolving silver in nitric acid and crystallising the product. It occurs in colourless, odourless,

transparent, tabular crystals, having a bitter, metallic taste. It should be **stored** protected from light.

Soluble in water (2 in 1) and alcohol (1 in 25); slightly soluble in ether and glycerin.

Standard, B.P.—Silver nitrate contains not less than 99·8 per cent. of AgNO_3 . It complies also with a limit test for copper, bismuth and lead.

Action and Uses.—Silver nitrate is a valuable caustic and astringent; when applied to living tissues it combines with the proteins forming a thick coating of white albuminate, which becomes brown and finally black as the silver salt is reduced to oxide. It is used to destroy warts and other small skin growths. Dilute solutions are disinfectant and astringent. Silver nitrate is, however, precipitated by chlorides, and for this reason many new silver compounds compatible with chlorides have been introduced. Silver salts taken internally are absorbed and if continued for long periods are deposited, combined with organic matter, in blue-grey granules. These granules are chiefly found in the connective tissue and produce the pigmentation of the skin, known as argyria, characteristic of chronic silver poisoning. Silver nitrate has been used internally for dyspepsia, vomiting, gastric catarrh and ulceration, diarrhoea, and for epilepsy, chorea and other nervous diseases. Clinical experience has shown that it is useless in epilepsy and it is very doubtful if any silver ever reaches the central nervous system.

If **administered** internally, silver nitrate should be prescribed in the form of pills, massed with kaolin ointment. All solutions of silver salts should be dispensed in amber-coloured, glass-stoppered bottles. Silver nitrate stains may be removed with solution of potassium cyanide. It is used **externally** in aqueous solution as an eye lotion, 0·2 to 0·6 per cent. w/v, as an application to the conjunctiva, 1 to 2 per cent. w/v, as an injection into the urethra, 0·025 to 0·2 per cent. w/v, as an application to ulcers of different kinds and to the fauces in inflammatory conditions, 2 to 6 per cent. w/v, and as a paint in pruritus ani or pruritus vulvæ, 1 per cent. w/v. A 5 per cent. solution in spirit of nitrous ether is used as an application to the skin for eczema and as a toughening agent for the prevention of bed sores. For cauterising purposes it is used in the form of *Argenti Nitras Mitigatus* or *Argenti Nitras Induratus*, the former containing only one-third its weight of the silver salt. A 1 per cent. w/v solution is a valuable prophylactic against ophthalmia neonatorum. It is an ingredient of hair dyes, a solution of pyrogallol usually being the reducing agent.

Silver nitrate is **incompatible** with alkalis, halogen acids and their salts, phosphates, hydrocyanic acid and its salts, tannin and astringent preparations, etc. In cases of **poisoning** with silver salts, demulcent drinks with a good proportion of common salt should be given. After vomiting has been induced, copious draughts of milk should be taken and, finally, a dose of castor oil.

Dose.—0·008 to 0·016 gramme ($\frac{1}{8}$ to $\frac{1}{4}$ grain).

Preparations

Argenti Nitras Induratus, B.P.—(Argent. Nit. Indur.)—Toughened Silver Nitrate. Silver nitrate and potassium nitrate fused together and poured into moulds. It contains not less than 94 per cent. and not more than 96 per cent. of AgNO_3 . It should be stored away from light.

Argenti Nitras Mitigatus, B.P.C.—(Argent. Nit. Mitig.)—Mitigated Silver Nitrate. *Syn.*—Mitigated Caustic; Argenti Nitras Dilutus. Silver nitrate and potassium nitrate fused together and poured into moulds. It contains not less than 32 per cent. and not more than 34 per cent. of AgNO_3 .

This preparation was included in the British Pharmacopœia, 1914.

ARGENTI OXIDUM

(Argent. Oxid.)

Silver Oxide

Silver oxide may be prepared by adding a slight excess of sodium, potassium, or calcium hydroxide to a solution of silver nitrate. The product should be well washed with recently boiled water, and dried below 80° . When prepared for use in conjunction with methyl iodide as a methylating agent, hot solutions of barium hydroxide and silver nitrate should be used and every care observed to prevent access of carbon dioxide during the preparation. It occurs as a heavy, brownish-black, inodorous powder, having an unpleasant, metallic taste. Some doubt exists concerning its stability at temperatures in the neighbourhood of 100° , but when heated above 250° rapid dissociation into metallic silver and oxygen ensues. When freshly precipitated it dissolves in solution of ammonia, the solution so formed leaving black crystals of $\text{Ag}_2\text{O} \cdot 2\text{NH}_3$ on evaporation which, when dry, explode with the minimum amount of friction. Its solution in water acts as a strong base, but the corresponding silver hydroxide has never been isolated. Silver oxide should be **stored** in amber-tinted bottles.

Very slightly **soluble** in water; insoluble in alcohol.

Standard.—Silver oxide, determined, after solution in nitric acid, by the method of the British Pharmacopœia for Argenti Nitras, contains not less than 99.5 per cent. of Ag_2O , calculated on the substance dried at 80° ; each millilitre of N/10 ammonium thiocyanate is equivalent to 0.01159 gramme of Ag_2O . Loss on drying at 80° , not more than 1 per cent. 1 gramme, dissolved in 1 millilitre of nitric acid and 4 millilitres of water, remains clear and colourless on the addition of slight excess of solution of ammonia (absence of copper, bismuth and lead).

Action and Uses.—Silver oxide has been used internally for gastric pain and dyspepsia, also in chorea and epilepsy. It is absorbed in minute amounts only. It has a milder and less irritating action than the nitrate, because of its slight solubility. It is **administered** in pills massed with kaolin ointment. If prescribed with creosote, phenol, or

other similar substance, it should first be mixed with some inert powder such as kaolin to prevent reduction as far as possible. Silver oxide is **incompatible** with bromides, iodides, chlorides, acids, ammonia, tannin and many organic substances. It may decompose with explosive violence if triturated with combustible or readily oxidisable substances.

Dose.—0·03 to 0·12 gramme ($\frac{1}{2}$ to 2 grains).

ARGENTI PROTEINAS

(Argent. Protein.)

Silver Proteinate

Synonyms—Argento-Proteinum Forte; Strong Silver Protein.

Silver proteinate may be prepared by the action of silver salts, or moist silver oxide, on albumose or gelatin in the presence of alkali. It occurs as a fine, brownish-yellow powder. Solutions of the salt are quite clear and are not coagulated by the action of heat, nor are they precipitated by the addition of alkali, alkali sulphides, alkali salts, or albumen; they do not stain the skin or clothes. The compound chars when heated, giving off an odour resembling that of burnt hair; on complete incineration, a greyish-white residue is left which gives the reactions of silver. When 5 millilitres of a 2 per cent. aqueous solution with 5 millilitres of sodium hydroxide solution is diluted with 10 millilitres of water, and 2 millilitres of a 2 per cent. copper sulphate solution added, a violet colouration appears after a few minutes. A 1 per cent. aqueous solution is alkaline to litmus and gives a precipitate with ferric chloride solution; with dilute hydrochloric acid it gives a precipitate of unaltered proteinate which is soluble on warming; with sodium chloride there is no immediate turbidity, and, after the addition of ammonia and treatment with hydrogen sulphide, a dark colouration is produced, but no precipitation. Mercuric chloride solution produces a white precipitate, the supernatant liquid becoming nearly colourless. It should be **stored** in well-stoppered bottles protected from light.

Soluble in water (1 in 2); almost insoluble in alcohol, chloroform and ether.

Standard.—Silver proteinate contains not less than 7·5 per cent. and not more than 8·5 per cent. of Ag. Shake 1 gramme with 10 millilitres of alcohol and filter; no turbidity is produced on the addition of 2 millilitres of dilute hydrochloric acid (limit of silver salts).

Assay.—Slowly incinerate about 3 grammes, accurately weighed, and heat the residue with 10 millilitres of nitric acid until no more coloured fumes are evolved; dilute to 150 millilitres and titrate with N/10 ammonium thiocyanate, using ferric ammonium sulphate solution

as indicator; each millilitre of N/10 ammonium thiocyanate is equivalent to 0.01079 gramme of Ag.

Action and Uses.—Silver proteinate is used for its local antiseptic properties. Compounds belonging to this group are much less germicidal than silver nitrate, but, relatively, they are non-corrosive and are less affected by body secretions. In strong solution (10 per cent. or more) silver proteinate is slightly irritating, but even strong solutions are non-astringent.

Silver proteinate is used for infections of the mucous membrane such as acute coryza, conjunctivitis, urethritis, tonsillitis, etc. For urethral injections, solutions of 1 or 2 per cent. are used, and, in tonsillitis, a 10 per cent. solution may be employed. In conjunctivitis, 2 to 10 per cent. solutions, and, for prevention of ophthalmia neonatorum, solutions up to 10 per cent. in strength have been used. Sometimes local argyria, especially of the eyelids, may occur from the use of silver proteinate. In acute gonorrhœa, solutions of from 0.25 to 1 per cent. and, in chronic gonorrhœa, solutions of from 2 to 10 per cent. are used; pessaries may contain from 5 to 10 per cent. For rectal irrigation, a solution of 0.1 per cent. may be employed; suppositories may contain from 5 to 10 per cent. Ointments, especially for ophthalmic use, may contain from 2 to 5 per cent. Solutions are best prepared by shaking the powder on to the surface of cold water and allowing it to dissolve slowly. They should be freshly prepared. Solutions of silver proteinate for **instillation** may be prepared by aseptic methods.

ARGENTI PROTEINAS MITE

(Argent. Protein. Mit.)

Mild Silver Proteinate

Synonyms—Argento-Proteinum Mite; Mild Silver Protein; Argenti Nucleinas; Silver Nucleinate; Argenti Vitellin; Silver Vitellin.

Mild silver proteinate is silver rendered colloidal by the action of protein and may be prepared by the action of denatured serum albumen, casein, or other suitable protein on moist silver oxide. It occurs as a brown powder, or nearly black scales or granules, which are odourless. It responds to the identity tests given under Argenti Proteinæ, but is less germicidal in its action.

Freely, but slowly, **soluble** in water; almost insoluble in alcohol, chloroform and ether.

Standard.—Mild silver proteinate, determined by the method for Argenti Proteinæ, contains not less than 19.0 per cent. and not more than 25.0 per cent. of Ag. It complies with the limit test for silver salts in Argenti Proteinæ.

Action and Uses.—Mild silver proteinate, and compounds belonging to the group, are designated mild owing to their lack of irritant qualities, and because their antiseptic properties are less than those of silver proteinate. The chief application of mild silver proteinate is as an antiseptic and as a mechanical cleanser of mucous membrane. It is used in the same conditions as silver proteinate, but is preferable when it is important to avoid irritation. In conjunctivitis, solutions of 25 per cent., or an ointment of 10 per cent. strength, may be employed. A 25 per cent. solution is used as a prophylactic of ophthalmia neonatorum, a 50 per cent. solution for application to corneal ulcers, and as a spray for the nose and throat, 10 to 20 per cent. solution, or, as a swab, 25 to 50 per cent. solution. For gonorrhœa, a 3 to 10 per cent. solution may be used for injection in the acute stages, and 10 to 20 per cent. in the chronic stages. As a urethral irrigation, 1 in 1000 solution is employed. Bougies may contain 1 or 2 per cent. In cystitis, solutions of 10 to 50 per cent. are used. Pessaries containing from 5 to 10 per cent. of mild silver proteinate are used in vaginitis. Mild silver proteinate has been administered by mouth as a gastro-intestinal antiseptic. Solutions of colloidal silver are opaque to X-rays and, in concentrations of 15 or 20 per cent., are employed in X-ray diagnosis of abnormal conditions of the kidney and bladder. Solutions of mild silver proteinate for **instillation** may be prepared by aseptic methods.

ARISTOLOCHIA

(*Aristoloch.*)

Aristolochia

Synonyms—Indian Birthwort; Sapsun.

Aristolochia consists of the dried stem and root of *Aristolochia indica* Linn. (Fam. Aristolochiaceæ), a shrubby, twining plant indigenous to India.

The pieces of stem, which form the greater part of the drug, vary in length, being usually about 10 centimetres, and are from 5 to 10 millimetres in diameter, yellowish-brown, sub-cylindrical, and twisted. The external surface is warty in most pieces, and the thinner pieces of stem are marked with longitudinal furrows and a few transverse fissures. The transversely cut surface exhibits a large porous wood in wedge-shaped portions, separated by a few wide medullary rays and surrounded by a thin yellowish-brown bark. The root is tortuous, reddish-brown in colour, and exhibits occasional transverse constrictions or fissures. The bark, like that of the stem, is thin and easily separated. The wood in the root resembles that of the stem. The fracture is short and uneven in the root; in the stem, it is short in the bark, while the wood bends without breaking. The drug has an aromatic odour, and a bitter, camphoraceous taste.

Aristolochia **contains** a bitter principle which may be alkaloidal

in nature, and a volatile oil which probably contains borneol; it is also said to contain aristin, aristic acid, resin, tannin and starch.

Action and Uses.—Aristolochia is used in India and the Eastern Colonies for its bitter properties, its action resembling that of gentian and serpentary. The action of the bitter principle resembles that of aloin, but it is more toxic and in large doses it may produce vomiting and purging. In rabbits it causes nephritis with albuminuria and uræmic symptoms. It is **administered** in the form of tincture, Tinctura Aristolochiæ, 1 in 5 of alcohol (70 per cent.); dose, 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

ARMORACIA

(Armor.)

Horseradish

Synonyms—Armoraciæ Radix; Horseradish Root.

Horseradish is the fresh root of cultivated plants of *Cochlearia Armoracia* Linn. (Fam. Cruciferae), a perennial herb indigenous to Eastern Europe, naturalised and cultivated in Great Britain. It may be collected at any season, but is most active in autumn and in early spring before the leaves appear.

The root is nearly cylindrical in shape, 25 to 40 or more centimetres in length and 2 to 4 centimetres in diameter; externally, it is pale yellowish-white and bears three double rows of fibrous rootlets or of the scars left by their removal; internally, it is almost white and when scraped or bruised, a characteristic, mustard-like odour develops; the taste is pungent. The upper part of the root is marked with transverse scars of leaves and has a greenish tint.

Horseradish **contains** the glycoside, sinigrin (potassium myronate), which is decomposed in the presence of water by the enzyme, myrosin, which is also present. The products of the decomposition are a volatile oil (allyl isothiocyanate), potassium acid sulphate and dextrose. The root also contains resin, sugar and starch. Alkaloids are absent.

Action and Uses.—Horseradish has been used as a counter-irritant in lumbago, sciatica and similar painful affections, and as a vesicant. Where the application of cantharidin is contra-indicated, the freshly pulped root is spread on the affected area and left for fifteen minutes, or until the required degree of reaction is produced. Spiritus Armoraciæ Compositus has carminative properties, and an infusion (1 in 20) has been used as a gargle, and administered as a stimulant.

Preparation

Spiritus Armoraciæ Compositus, B.P.C.—(Sp. Armor. Co.)—Compound Spirit of Horseradish. A distilled spirit representing 1 in 8 of horseradish, with dried bitter-orange peel and nutmeg. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

This spirit was included in the British Pharmacopœia, 1914.

ARNICÆ FLOS

(Arnic. Flos.)

Arnica Flower*Synonyms* —Arnicae Flores; Arnica Flowers.

Arnica flower consists of the dried flowerheads of *Arnica montana* Linn. (Fam. Compositæ), a small herbaceous perennial, indigenous to Central Europe. It should be **stored** in a cool, dry place.

The receptacle is nearly flat, from 3 to 8, mostly about 5·5, millimetres in diameter, with two rows of dark green, linear-lanceolate, pubescent, involucre bracts and is often found detached from the florets. The ray florets are from 2 to 3·5 centimetres long and number about 16; they possess conspicuous, orange-yellow, ligulate corollas, terminating in 3, or occasionally 4 or 5, acute teeth and traversed by 7 to 9, or rarely up to 15, veins. The disc florets are numerous with a 5-toothed, tubular corolla. The ovaries and fruits are 5-ribbed and are clothed with appressed twin hairs; they are surmounted by a pappus, the bristles of which are from 4 to 6 cells in diameter and are barbed by the exertion of the pointed apices of the cells. The flowers have an aromatic odour and an acrid bitter taste.

Arnica flower **contains** the bitter, yellow, crystalline body, arnicin, a volatile oil, and the colourless, crystalline phytosterol, arnisterol.

Substitutes.—The receptacles and involucre are sometimes removed so as to minimise the liability to insect attack. The flowerheads of *Inula britannica* Linn. are occasionally offered as arnica flower; they are distinguished by the 4-veined, ligulate corollas.

Standard.—Arnica flower contain not more than 2 per cent. of foreign organic matter. Proportion of receptacles with their attached involucre, not less than 25 per cent. and not more than 33 per cent. Alcohol-soluble extractive (45 per cent. alcohol), not less than 15 per cent.

Arnica flower, in powder (Pulvis Arnicae Floris : Pulv. Arnic. Flor.), contains the constituents of Arnicae Flos and complies with the limit for alcohol-soluble extractive of the unground drug.

Action and Uses.—Arnica flower has an irritant effect upon the stomach and intestines. As a local application for sprains and bruises, where the skin is not too tender or broken, the tincture, Tinctura Arnicae Floris, has been employed.

Preparation

Tinctura Arnicae Floris, B.P.C.—(Tinct. Arnic. Flor.)—Tincture of Arnica Flower. 1 in 10. Dose:—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopœia, 1914, under the name of Tinctura Arnicae Florum.

ARNICÆ RHIZOMA

(Arnic. Rhiz.)

Arnica Rhizome*Synonyms*—*Arnica Radix*; *Arnica Root*.

Arnica rhizome consists of the dried rhizome and rootlets of *Arnica montana* Linn. (Fam. Compositæ), a perennial with a small, creeping rhizome, indigenous to Central Europe. It is collected after the stem has died down in the autumn.

The rhizome is horizontal, cylindrical, dark brown, and varies from 2·5 to 5 centimetres in length and from 4 to 6 millimetres in thickness; it is usually curved, bearing brittle, wiry rootlets on its under surface, rough from the presence of encircling scars of cataphyllary leaves and scars left where roots have broken off, and often terminated by the hairy remains of the aerial stem and leaves. The transverse section exhibits a rather thick, yellowish cortex, near the inner margin of which is a circle of dark brown oleo-resin ducts; in the centre is a large pith surrounded by a circle of yellowish wood bundles. The odour is faint and aromatic, and the taste bitter and acrid.

Arnica rhizome **contains** from 0·5 to 1 per cent. of a volatile oil having a pungent, aromatic taste, and the bitter, yellow, crystalline principle, arnicin; tannin and inulin are also present, but starch is absent.

Substitutes.—Rhizomes of *Geum urbanum* Linn. (Fam. Rosacæ) and of species of *Hieracium* (Fam. Compositæ) are sometimes present. The former is distinguished by its clove-like odour and both by the absence of oleo-resin ducts.

Standard.—*Arnica* rhizome contains not more than 2 per cent. of foreign organic matter. Ash, not more than 12 per cent. Alcohol-soluble extractive (70 per cent. alcohol), not less than 14 per cent.

Arnica rhizome, in powder (*Pulvis Arnicæ Rhizomæ*: *Pulv. Arnic. Rhiz.*), contains the constituents of *Arnicæ Rhizoma* and complies with the limits for ash and alcohol-soluble extractive of the unground drug.

Action and Uses.—The action of *arnica* rhizome is the same as that of the flower. The tincture, with or without dilution with water, is a popular application for sprains and bruises when the skin is unbroken. Liniment of *arnica* is applied with friction as a mild counter-irritant, but cases of *arnica* dermatitis from the local application of *arnica* preparations have been reported.

Preparations

Linimentum Arnicæ, B.P.C.—(*Lin. Arnic.*)—Liniment of *Arnica*. *Syn.*—*Arnica Opodeldoc*. A solid preparation containing tincture of *arnica* root, 1 in 4, with hard soap, camphor and alcohol (90 per cent.).

Tinctura Arnicæ Radicis, B.P.C.—(*Tinct. Arnic. Rad.*)—Tincture of *Arnica Root*. *Syn.*—Tincture of *Arnica*. 1 in 20.

ARSENI TRIIODIDUM

(Arsen. Triiod.)

Arsenic Triiodide*Synonyms*—Arsenii Iodidum; Arsenious Iodide.

Arsenic triiodide may be obtained by the direct combination of arsenic and iodine and purification of the product by crystallisation from carbon disulphide, toluene, or other solvent. It occurs in small crystals of an orange-red colour. The crystalline masses of arsenic triiodide found in commerce are obtained by fusing the elements together; they contain uncombined iodine and arsenic and are not completely soluble in water, forming a yellow solution with blackish, insoluble flocks. An aqueous solution of arsenic triiodide has a strongly acid reaction due to partial hydrolysis. The solution is colourless at first, but becomes yellow on standing, owing to liberation of iodine.

Soluble in water (1 in 18), alcohol (1 in 42), ether, chloroform and carbon disulphide.

Standard, B.P.—Arsenic triiodide contains not less than 99.0 per cent. of AsI_3 . Residue on volatilisation, not more than 0.5 per cent. It does not lose iodine when heated at 100° .

Action and Uses. Arsenic triiodide has an action similar to that of arsenic trioxide. It may be administered in pills, massed with lactose and glycerin of tragacanth. More generally it is given in mixtures in the form of Donovan's solution (Liquor Arseni et Hydrargyri Iodidi), but this solution is **incompatible** with alkaloids and with many other substances and should preferably be prescribed alone.

Dose.—0.004 to 0.016 grammic ($\frac{1}{10}$ to $\frac{1}{4}$ grain).

Preparation

Liquor Arseni et Hydrargyri Iodidi, B.P.—(Liq. Arsen. et Hydrarg. Iod.)—

Solution of Arsenous and Mercuric Iodides. *Syn.*—Donovan's Solution. It contains 1 per cent. w/v of red mercuric iodide (limits, 0.95 to 1.05) and total arsenic equivalent to 1 per cent. w/v of arsenic triiodide (limits, 0.95 to 1.05), in distilled water. 1 millilitre contains the equivalent of about 0.01 grammic and 15 minims contains the equivalent of about $\frac{1}{2}$ grain of each salt. The arsenous compound in the solution is rapidly oxidised to the arsenic state by contact with air. The solution should be freshly prepared or, if not used immediately, it should be stored in well-filled containers protected from light. **Dose.**—0.3 to 1 millilitre (5 to 15 minims).

ARSENI TRIOXIDUM

(Arsen. Trioxid.)

Arsenic Trioxide

Synonyms—Acidum Arseniosum; Arsenious Anhydride; Arsenious Acid; Arsenious Oxide.

Arsenic trioxide is prepared by roasting arsenical ores and purifying

the product by resublimation. It occurs as a heavy, white powder, or in white, irregular lumps with a vitreous fracture usually with a stratified appearance, and often containing both the transparent and the opaque varieties. When heated it sublimes, forming transparent octahedral crystals. On the addition of stannous chloride solution to a dilute solution of arsenic trioxide in hydrochloric acid, a brown colouration or precipitate is produced.

Very slowly **soluble** in water (about 1 in 65), the rate depending upon the relative proportions of the two varieties present and upon the degree of subdivision, boiling water (1 in 20) and glycerin (about 1 in 8); slightly soluble in alcohol. It is more readily soluble in water in the presence of acids or alkalis.

Standard, B.P.—Arsenic trioxide contains not less than 99·8 per cent. of As_2O_3 . Residue on volatilisation, not more than 0·1 per cent. It complies also with a test for absence of arsenious sulphide.

Action and Uses.—Arsenic trioxide appears to possess a selective action upon the cells of the intestinal mucous membrane and is chiefly absorbed at this site. After absorption there is an augmented breakdown of proteins, an increase in the lactic acid content of the blood and in the nitrogen excreted in the urine. Arsenic trioxide is given internally because of its beneficial effect on metabolism, for its value as a general tonic and for its use in improving the appetite. There is no evidence, however, that it directly causes an increased formation of red blood cells in normal individuals. Inorganic forms of arsenic were used formerly in the treatment of protozoal diseases such as syphilis, malaria and trypanosomiasis, but organic arsenical compounds are now employed. Arsenic trioxide is believed to influence the nutrition of the skin and it is given, therefore, in such skin diseases as psoriasis and chronic eczema, which are affected probably by dilatation of the skin vessels. Large doses of arsenic trioxide are sometimes given in lymphadenoma and leukæmia. It is excreted much more slowly than pentavalent, organically combined, arsenic compounds, and for this reason cumulative poisoning is readily produced. Excessive doses of arsenic trioxide cause severe irritation of the alimentary canal, with vomiting and diarrhœa, and fatty degeneration of the liver occurs when a large quantity of arsenic is absorbed. Chronic poisoning, produced by repeated small doses, is shown by a discolouration of the skin, conjunctivitis, laryngitis, multiple peripheral neuritis and occasionally jaundice and cirrhosis.

Arsenic trioxide is **administered** usually as *Liquor Arsenicalis* in mixtures, or pills containing the oxide may be given. It is best administered after meals. Arsenic trioxide, mixed with morphine or cocaine, is used to destroy nerves before filling teeth, and arsenical solution mixed with tincture of ipecacuanha is employed in the treatment of pyorrhœa and stomatitis. Arsenic trioxide is commonly employed for the destruction of rats and mice, and as a constituent of weed-killers and sheep dips. In cases of acute arsenical **poisoning**,

Antidotum Arsenum should be administered; the stomach should subsequently be emptied, stimulants given, and warmth applied.

Dose.—0·001 to 0·005 gramme ($\frac{1}{80}$ to $\frac{1}{12}$ grain).

Preparations

Antidotum Arsenum, B.P.C.—(Antidot. Arsen.)—Arsenic Antidote. It contains freshly precipitated ferric hydroxide and light magnesium oxide. Dose.—120 millilitres (4 fluid ounces).

Liquor Arseni Acidus, B.P.C.—(Liq. Arsen. Acid.)—Acid Solution of Arsenic. *Syn.*—Liquor Arsenici Hydrochloricus. It contains from 0·95 per cent. to 1·05 per cent. w/v of arsenic trioxide in distilled water acidified with hydrochloric acid. 0·5 millilitre contains 0·005 gramme and 8 minims contains about $\frac{1}{12}$ grain of arsenic trioxide. Dose.—0·12 to 0·5 millilitre (2 to 8 minims).

This solution was included in the British Pharmacopœia, 1914, under the name of Liquor Arsenici Hydrochloricus.

Liquor Arseni Alkalinus, B.P.C.—(Liq. Arsen. Alk.)—Alkaline Solution of Arsenic. It contains from 0·95 per cent. to 1·05 per cent. w/v of arsenic trioxide in 1 per cent. w/v solution of potassium carbonate with compound tincture of lavender. 0·5 millilitre contains 0·005 gramme and 8 minims contains about $\frac{1}{12}$ grain of arsenic trioxide. Dose.—0·12 to 0·5 millilitre (2 to 8 minims).

This solution was included in the British Pharmacopœia, 1914, under the name of Liquor Arsenicalis.

Liquor Arsenicalis, B.P.—(Liq. Arsen.)—Arsenical Solution. *Syn.*—Solutio arsenicalis seu Fowleri I.A.; Fowler's Solution. A solution of arsenic trioxide, 1 per cent. w/v, in potassium hydroxide, neutralised with dilute hydrochloric acid (limits, 0·95 to 1·05). The growth of fungus may be prevented by sterilising the solution in the containers by boiling for half an hour. 0·5 millilitre contains 0·005 gramme and 8 minims contains about $\frac{1}{12}$ grain of arsenic trioxide. Dose.—0·12 to 0·5 millilitre (2 to 8 minims).

Liquor Auri et Arseni Brominatus, B.P.C.—(Liq. Aur. et Arsen. Brominat.)—Brominated Solution of Gold and Arsenic. *Syn.*—Liquor Auri et Arsenii Bromidi; Liquor Auri Bromidi Arsenatus. 0·6 millilitre contains the equivalent of 0·0028 gramme of arsenic trioxide and 0·002 gramme of auric bromide; 10 minims contains the equivalent of $\frac{1}{12}$ grain of arsenic trioxide and $\frac{1}{12}$ grain of auric bromide. Dose.—0·3 to 0·6 millilitre (5 to 10 minims).

Liquor Potassii Arsenatis et Bromidi, B.P.C.—(Liq. Pot. Arsen. et Brom.)—Solution of Potassium Arsenate and Bromide. *Syn.*—Liquor Arsenii Bromidi; Clemens' Solution. A solution containing potassium arsenate and potassium bromide, prepared from arsenic trioxide, 1 per cent. w/v, with potassium bicarbonate, bromine and distilled water. Dose.—0·12 to 0·5 millilitre (2 to 8 minims).

Pasta Arsenicalis, B.P.C.—(Past. Arsen.)—Arsenical Paste. Arsenic trioxide, 2 parts, and morphine hydrochloride, 1 part, mixed to a paste with creosote.

Pilulæ Asiaticæ, B.P.C.—(Pil. Asiatic.)—Asiatic Pills. Each pill contains $\frac{1}{12}$ grain of arsenic trioxide and $\frac{1}{4}$ grain of pepper. Dose.—1 pill.

Pilulæ Ferri Carbonatis cum Arseno et Strychnina, B.P.C.—(Pil. Ferr. Carb. c. Arsen. et Strych.)—Pills of Iron Carbonate with Arsenic and Strychnine. *Syn.*—Blaud's Pills with Arsenic and Strychnine. Each pill contains $\frac{1}{12}$ grain of arsenic trioxide, $\frac{1}{12}$ grain of strychnine hydrochloride and 5 grains of pill of iron carbonate. Dose.—1 or 2 pills.

Pilulæ Ferri Carbonatis et Arseni, B.P.C.—(Pil. Ferr. Carb. et Arsen.)—Pills of Iron Carbonate and Arsenic. *Syn.*—Blaud's Pills with Arsenic. Each pill contains $\frac{1}{10}$ grain of arsenic trioxide and 5 grains of pill of iron carbonate. Dose.—1 pill.

Pilulæ Ferri et Arseni, B.P.C.—(Pil. Ferr. et Arsen.)—Iron and Arsenic Pills. *Syn.*—Pilulæ Ferri Arsenicales. Each pill contains 3 grains of exsiccated ferrous sulphate and $\frac{1}{10}$ grain of arsenic trioxide. Dose.—1 pill.

ARSPHENAMINA

(Arsphenamin.)

Arsphenamine

Synonyms—Arsenobenzol; Arsenobenzene.

Arsphenamine may be prepared by the reduction of 3-nitro-4-hydroxyphenylarsonic acid in aqueous solution with sodium hyposulphite, in the presence of magnesium chloride, at 50° to 60° and the conversion of the base into its dihydrochloride. It consists mainly of the dihydrochloride of 3 : 3'-diamino-4 : 4'-dihydroxyarsenobenzene, $(\text{NH}_2)(\text{OH})\text{C}_6\text{H}_3\text{As} : \text{AsC}_6\text{H}_3(\text{OH})(\text{NH}_2), 2\text{HCl}$. It is distributed in sealed glass phials from which air has been evacuated or replaced by an inert gas. It occurs as a pale yellow to yellow, dry, amorphous powder, freely mobile in contact with glass surfaces and without odour, except that due to traces of ether. An aqueous solution (1 in 100) is acid to litmus, but does not change the colour of congo-red paper to blue.

One millilitre of a 1 per cent. solution of arsphenamine, treated with 1 drop of a 5 per cent. solution of sodium nitrite, turns bright orange and 0.5 millilitre of the solution so produced, added to 1 millilitre of a 2 per cent. solution of betanaphthol in 2N sodium hydroxide, produces a clear, wine-red solution. Arsphenamine is soluble in 8 per cent. solution of sodium hydroxide, but not in saturated solution of sodium bicarbonate; the latter liberates the insoluble base with effervescence. It decolourises iodine solution and gives a precipitate with silver nitrate. The crystalline product obtained by the following process melts between 130° and 132°:—Suspend 1 gramme of arsphenamine in 5 millilitres of 2N ammonia and add 6 millilitres of hydrogen peroxide solution with stirring; when dissolved add 5 millilitres of 2N hydrochloric acid and 1 gramme of charcoal, stir well for one minute, filter, and add 1 millilitre of 2N ammonia; after ten minutes remove the 3-amino-4-hydroxyphenylarsonic acid which crystallises on stirring, wash and add it to a solution of 1 gramme of acetylacetamide in 20 millilitres of water; heat until solution is complete, add 0.2 gramme of charcoal, boil for thirty seconds and filter; cool until a slight permanent opalescence is produced, and gently rub with a glass rod until crystallisation is induced; keep for a few minutes, filter, wash with cold water and dry at 95°. Arsphenamine should be **stored** at a temperature below 15°, and is then stable for at least two years.

Readily **soluble** in water and methyl alcohol; sparingly soluble in alcohol.

Standard.—Arsphenamine is controlled by regulations made under the Therapeutic Substances Act, 1925. The standard preparation for Great Britain and Northern Ireland is a quantity of arsphenamine kept in the National Institute for Medical Research, London. It complies with biological tests, carried out in an institution or laboratory approved by the licensing authority, for maximum toxicity and therapeutic potency. It contains, when determined by an approved method, not less than 30 and not more than 34 per cent. of As. When 0.5 gramme of the powder is added to 35 millilitres of water at 20°, it dissolves completely within fifteen minutes, yielding a clear, pale yellow solution, free from suspended particles. When 1 millilitre of a 15 per cent. aqueous solution of sodium hydroxide is added to this solution of arsphenamine, it causes a preliminary separation of the insoluble arseno-base, which, on gently shaking, redissolves in the excess of alkali to form a clear, bright yellow solution. This solution, diluted to 250 millilitres with a 0.5 per cent. sodium chloride solution, gives a clear, light yellow solution. The product in sealed phials, kept at a temperature of 56° for not less than twenty-four hours, retains its colour, physical properties and solubility.

Assay.—The proportion of arsenic may be determined by the method given under Sodii Aminarsonas.

Action and Uses.—It was due to Ehrlich's hypothesis, that pentavalent arsenicals such as sodium aminarsonate are reduced in the body to the trivalent form, that the spirochætidal power of the arsphenamines was realised. The therapeutic application of this research constitutes the greatest achievement yet made, not only in the treatment of syphilis but in the whole of chemotherapy (see Neoarsphenamina).

Arsphenamine is **administered** by intravenous injection. It is too irritant to be given subcutaneously or intramuscularly. For intravenous **injection** a slightly alkaline solution containing the di-sodium salt is prepared. This is less toxic than either the base or the mono-sodium salt, and is formed by dissolving the contents of a sealed container in cold, sterilised and recently distilled water, adding a 15 per cent. solution of sodium hydroxide until the precipitate first formed redissolves and then diluting with 0.5 per cent. solution of sodium chloride in cold, sterilised and recently distilled water so that each 50 millilitres of solution contains 0.1 gramme of arsphenamine. All solutions of arsphenamine should be freshly prepared immediately before use from material that is not discoloured. Arsphenamine has, almost completely, yielded place to neoarsphenamine in therapeutics, because of the difficulty of its preparation for injection and its much greater toxicity.

Dose.—0.1 to 0.6 gramme (1½ to 10 grains), by intravenous injection.

ARSPHENAMINA ARGENTICA

(Arsphenamin. Argent.)

Silver Arsphenamine

Silver arsphenamine is the sodium salt of silver 3 : 3'-diamino-4 : 4'-dihydroxyarsenobenzene and may be prepared by the action of a soluble silver salt on arsphenamine. It occurs as an odourless, brownish-black powder. It is distributed in glass phials, which are either evacuated or filled with an inert gas, and hermetically sealed. It should be **stored** at a temperature which does not rise above 15°.

Readily **soluble** in water.

Standard.—Silver arsphenamine is controlled by regulations made under the Therapeutic Substances Act, 1925. It complies with biological tests, carried out in an institution or laboratory approved by the licensing authority, for maximum toxicity and therapeutic potency. It contains, when determined by an approved method, not less than 18 per cent. and not more than 21 per cent. of As, and not less than 12 per cent. and not more than 13 per cent. of Ag. The aqueous solution, 1 in 20, is almost black in colour and is alkaline to litmus. The aqueous solution gives no precipitate on the addition of sodium hydroxide or sodium carbonate, but a precipitate is produced on the addition of sodium bicarbonate.

Assay.—For arsenic. The proportion of arsenic may be determined by the method given under Sodii Aminarsonas, using 0.25 gramme.

For silver. Dissolve about 0.25 gramme, accurately weighed, in 10 millilitres of water, add 5 grammes of ammonium persulphate and boil until colourless; dilute to about 50 millilitres with water, add 1 millilitre of nitric acid and titrate with N/50 ammonium thiocyanate, using ferric ammonium sulphate as indicator; each millilitre of N/50 ammonium thiocyanate is equivalent to 0.002158 gramme of Ag.

Action and Uses.—Silver arsphenamine has about twice the spirochætidal value of arsphenamine, but is, however, more toxic. It is given intravenously and is used in advanced cases of syphilis. Sometimes silver arsphenamine is still given in early cases, but usually it is reserved for syphilis of the central nervous system. Solutions for **injection** are prepared by dissolving the contents of a sealed container in sterilised water.

Dose.—0.1 to 0.6 gramme (1½ to 10 grains), by intravenous injection.

ASAFÆTIDA

(Asafæt.)

Asafetida

Asafetida is an oleo-gum-resin obtained from the living rhizome and root of *Ferula fætida* Regel, *F. rubricaulis* Boiss., or other

species of *Ferula* (Fam. Umbelliferae), indigenous to Eastern Persia and Western Afghanistan. In the cortex of the stem and root are numerous large, schizogenous ducts containing a milky emulsion which exudes when the ducts are wounded. The drug is obtained by cutting off the stem close to the crown of the root; the exuded juice hardens and is then scraped off. It should be **stored** in well-closed containers in a cool place.

The oleo-gum-resin occurs in rounded or flattened tears, mostly from 12 to 25 millimetres in diameter, or in masses of agglutinated tears, greyish-white to dull yellow in colour. The tears are yellowish and translucent or milky-white and opaque internally, but the freshly fractured surface slowly darkens on exposure to the air, becoming pink, then red, and finally reddish-brown. The fractured surface acquires a bright red or reddish-brown colour when touched with sulphuric acid, becoming violet when the acid is washed off; the freshly broken surface, touched with a drop of nitric acid (50 per cent. v/v), gives a green colouration. Asafetida forms a white emulsion when triturated with water. It has a powerful and persistent alliaceous odour and a bitter, acrid, alliaceous taste.

Asafetida **contains** about 40 to 64 per cent. of resin, 25 per cent. of gum, and 6 to 17 per cent. of volatile oil. The resin consists of asaresinotannol partly free and partly combined with ferulic acid. The volatile oil contains in the lower boiling fraction two terpenes, one apparently identical with pinene, while from the higher boiling portions the disulphides, $C_7H_{14}S_2$ and $C_{11}H_{20}S_2$, have been separated. The drug also contains free ferulic acid, water, and small quantities of various impurities. Pure tear asafetida usually contains from 65 to 75 per cent. of substances soluble in alcohol, and yields about 3 to 5 per cent. of ash. When a 10 per cent. tincture, obtained by boiling the drug, powdered by trituration with sand, with alcohol (90 per cent.), is filtered into an equal volume of alcohol (90 per cent.), previously rendered alkaline by the addition of 10 per cent. of dilute solution of ammonia, no fluorescence is produced (distinction from galbanum). When asafetida is boiled for some minutes with hydrochloric acid and the solution then made alkaline with ammonia solution and diluted, a blue fluorescence is produced (presence of combined umbelliferone).

Substitute.— Mass asafetida consists of an agglutinated mass of tears mixed with various extraneous materials such as stones, slices of the root, gypsum, earthy matter, etc. Asafetida in the form of paste also occurs in commerce, it is often purplish-red when fresh, and slowly darkens and hardens on keeping. Powdered asafetida does not represent the official drug.

Standard, B.P.—Asafetida yields not more than 50 per cent. of matter insoluble in alcohol (90 per cent.). Ash, not more than 15 per cent.

Action and Uses.—Asafetida is used as a carminative in flatulence and as a sedative in hysterical and allied conditions. It is used as an

enema for intestinal flatulence. *Tinctura Asafœtidæ* contains the resin and volatile oil, the gum being insoluble in the alcohol used in its preparation. *Spiritus Ammoniaë Fetidus* is an alcoholic solution of the volatile oil and resin to which ammonia has been added; the resin gives it a diuretic action. When it is desirable to cover the taste and odour of asafetida, it should be administered in pills. The best excipient is water, and the pills should be coated, first with a thin layer of acacia (by moistening with mucilage of acacia and afterwards drying), and then with sandarac varnish, or they may be pearl-coated. Pills containing asafetida should be well varnished before silvering, otherwise the sulphuretted oils of the drug turn the silver black. Asafetida is often combined with valerian or valerianates, and when the tincture is added to water, mucilage of acacia should be added to suspend the resin.

Dose.—0·3 to 1 gramme (5 to 15 grains).

SAGAPENUM.—Sagapenum is the gum-resin obtained from a species of *Ferula*, said by some authorities to be *Ferula persica* Willd., and by others to be *F. Szowitziana* DC. (Fam. Umbelliferae), growing in Arabia and Persia. It occurs either in separate, broken tears, or in masses. The tears vary in colour from yellow to yellowish-red and are more or less translucent. Masses are dark brownish or reddish-yellow, with a granular, resinous fracture, slightly translucent in small fragments. The odour is alliacious, but more aromatic and not so strong as that of asafetida. The taste is nauseous, bitter and acrid. The surface of fractured tears does not appear pink (distinction from asafetida). It is partly soluble in alcohol and in ether. Sagapenum contains resin, 50 to 60 per cent., gum, 23 to 30 per cent., and volatile oil, containing sulphur, 3 to 11 per cent. The resin contains umbelliferone and sagaresinotannol. A mixture of galbanum and asafetida has been sold as sagapenum. Sagapenum has been employed similarly to asafetida and galbanum in amenorrhœa and hysteria, but it is now rarely used. **Dose.**—0·6 to 2 grammes (10 to 30 grains).

Preparations

Pilula Aloes et Asafœtidæ, B.P.—(Pil. Aloes et Asafœt.)—Pill of Aloes and Asafetida. Aloes and asafetida, of each about 30 per cent., with hard soap and syrup of liquid glucose. **Dose.**—0·25 to 0·5 gramme (4 to 8 grains).

Pilula Asafœtidæ, B.P.C.—(Pil. Asafœt.)—Asafetida Pills. Each pill contains 3 grains of asafetida. **Dose.**—1 or 2 pills.

Pilula Galbani Compositæ, B.P.C.—(Pil. Galban. Co.)—Compound Pills of Galbanum. *Syn.*—Compound Pills of Asafetida. Each pill contains 1 grain each of asafetida, galbanum and myrrh. **Dose.**—1 or 2 pills.

Spiritus Ammoniaë Fetidus, B.P.C.—(Sp. Ammon. Fetid.)—Fetid Spirit of Ammonia. A distilled spirit representing 7·5 per cent. w/v of asafetida and containing 10 per cent. v/v of strong solution of ammonia. **Dose.**—For a single administration, 4 to 6 millilitres (1 to 1½ fluid drachms); for repeated administration, 1·2 to 2·5 millilitres (20 to 40 minims).

This spirit was included in the British Pharmacopœia, 1914.

Tinctura Asafœtidæ, B.P.—(Tinct. Asafœt.)—Tincture of Asafetida. 1 in 5, prepared by maceration in alcohol (70 per cent.). **Dose.**—2 to 4 millilitres (½ to 1 fluid drachm).

ATROPINA

(Atrop.)

Atropine

Atropine is *dl*-hyoscyamine, an alkaloid obtained by the racemisation of *l*-hyoscyamine extracted from *Atropa Belladonna* Linn., *Hyoscyamus muticus* Linn., and other solanaceous plants. It occurs in colourless, odourless, acicular crystals, or as a microcrystalline powder, and gives an alkaline solution in water. Atropine may be distinguished from hyoscyamine by the melting-point of its aurichloride. The aurichloride is precipitated when a solution of gold chloride is added to a 1 per cent. solution of the alkaloidal base in water acidified with hydrochloric acid, and is purified by recrystallisation from boiling water acidified with hydrochloric acid. Atropine aurichloride melts at 137° to 139°; hyoscyamine aurichloride melts at about 165°. When a trace of atropine is mixed with a few drops of nitric acid and evaporated to dryness on a water-bath, the residue has a faintly yellow colour which changes to violet on being moistened with freshly prepared alcoholic potassium hydroxide solution. This reaction is also given by hyoscyamine and by hyoscyne but not by homatropine.

Soluble in water (about 1 in 500), alcohol (1 in 3), ether (about 1 in 16) and chloroform.

Standard, B.P.—Atropine has a melting-point of 114° to 116°. Ash, not more than 0.1 per cent. It complies with a limit test for *l*-hyoscyamine and with tests for the absence of apoatropine, readily carbonisable substances, and many other alkaloids.

Action and Uses.—The action of atropine is in the main twofold. Firstly, it stimulates the central nervous system, where it acts especially on the motor area, affecting co-ordinated movements and causing, in large doses, restlessness, talkativeness and delirium. Secondly, it paralyses the terminations of the parasympathetic nerves which supply glands, plain muscle and the heart. To lessen secretions atropine is of service when taken internally. It is of value in diminishing excessive salivation, bronchial secretion and secretion of gastric juice. By virtue of its depressant action on the vagus, atropine quickens the heart rate and is of use in cases of poisoning by muscarine, pilocarpine and the like, where the slowing of the heart is marked. It has been found that in patients suffering from typhoid fever there is lessened vagal control and that atropine causes little or no increase in the pulse rate. The use of atropine before the administration of an anæsthetic is of value partly as a stimulant to the respiratory centre and partly for its action in diminishing secretions. It is often combined with morphine.

The action of atropine on the gut is complicated; small doses diminish peristalsis while large doses increase the activity of the gut. The first

action is due to paralysis of the vagal endings while the latter action may be due to stimulation of Auerbach's plexus. Atropine is added to purgatives to prevent griping. In ophthalmology, atropine is extensively used. In small doses, applied in solution or in the form of lamella or ointment to the conjunctiva, the pupil is dilated and accommodation paralysed. In this way rest of an inflamed organ is ensured. It has the disadvantage that its effect is extraordinarily persistent and may last for several days. A further disadvantage is that since atropine causes a rise in intra-ocular tension, a case of latent glaucoma may be precipitated into an acute attack. To relax spasmodic contractions of involuntary muscle, atropine is of considerable value and is used for this purpose in renal and biliary colic and in asthma. Perhaps this action may also explain the beneficial effects which follow its use in incontinence of urine in children. Atropine diminishes uterine contractions and is used in the treatment of dysmenorrhœa. A rash may follow the administration of this drug.

In cases of **poisoning** by atropine, when taken by the mouth (not uncommonly taken in the form of belladonna fruits by children), 1·2 grammes (20 grains) of tannic acid should be given in 120 millilitres (4 fluid ounces) of water, and then the stomach evacuated by means of a syphon tube or emetic. Morphine has been advised although its use cannot be recommended. After hypodermic injection, chloroform and ether may be helpful in controlling the spasms. In the stage of depression which follows that of excitement, caffeine should be used and artificial respiration employed. Pilocarpine is useless.

Dose.—0·00025 to 0·001 gramme ($\frac{1}{3200}$ to $\frac{1}{800}$ grain).

Preparations

Chloroformum Atropinæ, B.P.C.—(Chlorof. Atrop.)—Chloroform of Atropine. Atropine, about 1 in 220, in chloroform, coloured with alkanna.

Colloidum Atropinæ, B.P.C.—(Collod. Atrop.)—Atropine Collodion. Atropine, about 1 in 220, in acetone and acetone collodion.

Unguentum Atropinæ, B.P.C.—(Ung. Atrop.)—Atropine Ointment. Atropine, 1 per cent., in white soft paraffin.

The atropine ointment of the British Pharmacopœia, 1914, contained atropine, 2 per cent. w/w, and oleic acid, 8 per cent. w/w, in lard.

ATROPINÆ SULPHAS

(Atrop. Sulph.)

Atropine Sulphate

Atropine sulphate is the sulphate of the alkaloid atropine. It occurs in colourless, odourless crystals, or as a white, microcrystalline powder. The alkaloidal base is precipitated when the aqueous solution is rendered alkaline by the addition of sodium hydroxide solution and, when washed and dried, it responds to the reactions given under Atropina.

Soluble in water (about 2 in 1), and alcohol (1 in 4); insoluble in ether and chloroform.

Standard, B.P.—Atropine sulphate, when dried at 136° , has a melting-point of 195° to 196° . Loss on drying at 105° , not more than 3 per cent. Ash, not more than 0.1 per cent. It complies also with a limit test for hyoscyamine and with a test for the absence of apoatropine.

Action and Uses.—The action of atropine sulphate is identical with that of the alkaloid. This salt is generally employed in making hypodermic solutions and other preparations containing atropine. *Liquor Atropinæ Sulphatis* is used, either alone or diluted with sterilised water, for the eyes. *Lamellæ Atropinæ* are prepared for ophthalmic use. As a substitute for glycerin of belladonna, *Glycerinum Atropinæ* will be found more cleanly. Atropine salts are **incompatible** with alkalis, tannic acid and salts of mercury. A solution for **injection** may be sterilised by tyndallisation or by filtration, and the containers should comply with the tests for limit of alkalinity of glass. The treatment of cases of **poisoning** by atropine salts is described under *Atropina*.

Dose. 0.00025 to 0.001 gramme ($\frac{1}{4000}$ to $\frac{1}{1000}$ grain).

ATROPINÆ METHYLBROMIDUM.—Atropine methylbromide or mydriastine, $C_{17}H_{23}O_3N, CH_3Br$, is an addition compound of the alkaloid and methyl bromide and occurs in white crystals, melting at about 222° . It is readily soluble in water (1 in 1), slightly soluble in alcohol, and insoluble in chloroform and ether. It is given internally for the same purposes as atropine, but has less action on the heart and brain. It is used as a mydriatic in 0.5 to 2 per cent. solution, the effect passing off more rapidly than that of atropine. Dose—0.001 to 0.002 gramme ($\frac{1}{1000}$ to $\frac{2}{500}$ grain).

ATROPINÆ METHYLNITRAS.—Atropine methylnitrate, $C_{17}H_{23}O_3N, CH_3NO_3$, may be prepared by the interaction of atropine methylbromide and silver nitrate. It occurs as a white, crystalline powder, soluble in water. It is used as a mydriatic in 1 to 5 per cent. aqueous solution and has been given internally in the treatment of various spastic conditions. Atropine methylnitrate is administered subcutaneously prior to operations on the oral cavity in order to diminish the secretion of saliva. Dose—0.001 to 0.002 gramme ($\frac{1}{1000}$ to $\frac{2}{500}$ grain).

ATROPINÆ SALICYLAS.—Atropine salicylate, $C_{17}H_{23}O_3N, C_7H_5O_3$, occurs as colourless crystals, or as a white, crystalline powder. It is soluble in water (1 in 20) and in alcohol.

Preparations

Glycerinum Atropinæ, B.P.C.—(Glycer. Atrop.)—Glycerin of Atropine. Atropine sulphate, 1 in 400, in compound tincture of lavender and glycerin.

Lamella Atropinæ, B.P.—(Lamell. Atrop.)—Lamella of Atropine. Each lamella contains 0.000013 gramme ($\frac{1}{100000}$ grain) of atropine sulphate.

Liquor Atropinæ Sulphatis, B.P.C.—(Liq. Atrop. Sulph.) Solution of Atropine Sulphate. Atropine sulphate, 1 per cent w/v, in distilled water. Dose.—0.03 to 0.06 millilitre ($\frac{1}{2}$ to 1 minim).

This solution, prepared with recently boiled and cooled distilled water, was included in the British Pharmacopœia, 1914. It is intended for internal administration only.

Oculentum Atropinæ, B.P.—(Oculent. Atrop.)—Atropine Ointment for the Eye. Atropine sulphate, 0·25 per cent., in simple eye ointment. It should be stored in small, well-closed containers, in a cool place, and protected from light.

Oculentum Atropinæ of the British Pharmaceutical Codex, 1923, is included under the name of Unguentum Atropinæ (see Atropina).

Oculentum Atropinæ cum Hydrargyri Oxido, B.P.—(Oculent. Atrop. c. Hydrarg. Oxid.)—Atropine and Yellow Mercuric Oxide Ointment for the Eye. Atropine sulphate, 0·125 per cent., and yellow mercuric oxide, 1 per cent., in simple eye ointment. It should be stored in small, well-closed containers, in a cool place, and protected from light.

An ointment for the eye, prepared with moist yellow mercuric oxide ointment, atropine and yellow soft paraffin, was included in the British Pharmaceutical Codex, 1923.

Oculentum Atropinæ et Cocainæ, B.P.C.—(Oculent. Atrop. et Cocain.)—Atropine and Cocaine Eye Ointment. Atropine sulphate, about 0·25 per cent., and cocaine hydrochloride, about 0·5 per cent., in simple eye ointment.

Oculentum Iodoformi et Atropinæ, B.P.C.—(Oculent. Iodof. et Atrop.)—Iodoform and Atropine Eye Ointment. Iodoform, about 5 per cent., and atropine sulphate, about 0·1 per cent., in simple eye ointment.

AURANTII CORTEX RECENS

(Aurant. Cort. Rec.)

Fresh Bitter-Orange Peel

Fresh bitter-orange peel is the fresh, outer part of the pericarp of the ripe, or nearly ripe, fruit of *Citrus Aurantium* Linn. subsp. *amara* Engl. (Fam. Rutaceæ). Bitter oranges are cultivated chiefly in the south of Spain (Seville) and in Sicily (Palermo); the fruits are collected before they are quite ripe, the ripening usually being completed during transport. The peel is removed with as little as possible of the white "zest" adhering, but at the same time care is taken to avoid unnecessarily rupturing the oil glands which are situated in considerable number just below the epidermis of the fruit. The peel is best obtained during February and March since the Spanish fruit is not usually imported until the end of January.

The outer surface is pitted and is of a red or deep orange-red colour, internally only a very small amount of the white, spongy part of the pericarp is attached. The drug has a fragrant odour, and an aromatic bitter taste. The transversely cut surface moistened with hydrochloric acid assumes a dark green colour, a reaction which is sometimes useful in identifying the drug.

The diagnostic **microscopical** characters are the small, polygonal epidermal cells; the parenchymatous tissue situated below the epidermis, containing large oil glands and numerous crystals of calcium oxalate.

Bitter-orange peel **contains** volatile oil and an amorphous, glycosidal bitter principle, aurantiumarin. Other constituents are hesperidin, a colourless, tasteless, crystalline glycoside, which occurs chiefly in

the white "zest" of the peel, *isohesperidin*, *hesperic acid*, a bitter resin and *aurantiamaric acid*.

Standard, B.P.—Fresh bitter-orange peel is required to contain but little of the white, spongy part of the pericarp.

Action and Uses.—Fresh bitter-orange peel is used as a flavouring agent and for its bitter, stomachic and carminative properties.

Preparations

Elixir Simplex, B.P.C.—(Elix. Simp.)—Simple Elixir. Tincture of orange, about 1 in 13, with syrup and distilled water. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Extractum Aurantii Liquidum, B.P.C.—(Ext. Aurant. Liq.)—Liquid Extract of Orange. About 1 in 1. Dose.—0·6 to 1·2 millilitres (10 to 20 minims).

Syrupus Aurantii, B.P.—(Syr. Aurant.)—Syrup of Orange. Tincture of orange, 1 in 8, with syrup. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Tinctura Aurantii, B.P.—(Tinct. Aurant.)—Tincture of Orange. Fresh bitter-orange peel, about 1 in 4, prepared by maceration in alcohol (90 per cent.). Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

AURANTII CORTEX SICCATUS

(Aurant. Cort. Sicc.)

Dried Bitter-Orange Peel

Synonym—Aurantii Amari Cortex.

Dried bitter-orange peel is the dried, outer part of the pericarp of the ripe, or nearly ripe, fruit of *Citrus Aurantium* Linn. subsp. *amara* Engl. (Fam. Rutaceæ). It is imported chiefly from Malta, usually in narrow, machine-cut strips (gelatin cut), or in wider spiral strips. Owing to excessive rupturing of the oil glands it is not equal in aroma to hand-cut, English-dried peel.

Dried bitter-orange peel possesses the characters and diagnostic microscopical features of the fresh peel. The fracture is short. It yields to alcohol (60 per cent.) about 30 to 40 per cent. of extractive.

Substitutes.—Larger pieces or "quarters" are sometimes seen in commerce, but they have much of the white "zest" attached to them. Dried sweet-orange peel may sometimes be mixed with that of the bitter-orange. It may be distinguished by its paler, more yellowish colour, and by being thinner and much less bitter in taste. Lemon peel is scarcely changed in colour by hydrochloric acid. Indian orange peel (Aurantii Cortex Indicus) is the fresh or the dried, outer part of the pericarp of varieties of *C. Aurantium* Linn. grown in India and Ceylon.

Standard, B.P.—Dried bitter-orange peel is required to contain not more than a very small amount of the white, spongy part of the pericarp.

Action and Uses.—Dried bitter-orange peel is used in many preparations as a flavouring agent, and for its bitter stomachic and carminative properties.

Preparations

Infusum Aurantii Compositum Concentratum, B.P.C.—(Inf. Aurant. Co. Conc.)—Concentrated Compound Infusion of Orange Peel. This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh compound infusion of orange peel and differs also in containing a small proportion of alcohol. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Infusum Aurantii Compositum Recens, B.P.C.—(Inf. Aurant. Co. Rec.)—Fresh Compound Infusion of Orange Peel. Dried bitter-orange peel, 1 in 40, with lemon peel and clove. When compound infusion of orange peel or Infusum Aurantii Compositum is prescribed, fresh infusion not being specified, either Infusum Aurantii Compositum Recens, or Infusum Aurantii Compositum Concentratum, suitably diluted, may be dispensed. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

This infusion was included in the British Pharmacopæia, 1914, under the name of Infusum Aurantii Compositum.

Infusum Aurantii Concentratum, B.P.—(Inf. Aurant. Conc.)—Concentrated Infusion of Orange Peel. Dried bitter-orange peel, about 1 in $2\frac{1}{2}$, extracted with alcohol (25 per cent.). This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh infusion of orange peel and differs also in containing a small proportion of alcohol. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

A concentrated infusion, prepared with dilute chloroform water, alcohol (90 per cent.) and tincture of orange, was included in the British Pharmaceutical Codex, 1923.

Infusum Aurantii Recens, B.P.—(Inf. Aurant. Rec.)—Fresh Infusion of Orange Peel. 1 in 20. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Syrupus Aromaticus, B.P.C.—(Syr. Aromat.)—Aromatic Syrup. Liquid extract of orange peel, 1 in 16, with cinnamon water and syrup. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This syrup replaces the aromatic syrup of the British Pharmacopæia, 1914, which was prepared with 25 per cent. v/v of tincture of orange, 25 per cent. v/v of cinnamon water, and syrup.

AURI BROMIDUM

(Aur. Brom.)

Potassium Bromaurate

Synonym—Gold Bromide.

Potassium bromaurate may be obtained by the action of bromine water on gold in the presence of the equivalent of potassium bromide. It occurs as a blackish or brown powder, or in reddish crystals.

Soluble in water (1 in 5) and alcohol.

Action and Uses.—The principal action of gold salts is on metabolism. They are reputed to have the power of facilitating the absorption of pathological connective tissue. Potassium bromaurate is used for various forms of nervous diseases, especially those of an hysterical

nature, but with doubtful success. Its use for removing scar tissue and in epilepsy is not based upon any reliable evidence. It has also been employed in inveterate cases of tertiary syphilis. On the alimentary canal it exerts the ordinary effects of the metals, and in large doses will produce vomiting and diarrhœa. When injected into the circulation it produces an effect like that of arsenic. The salts of gold are commonly **administered** in solution or in pills prepared by rubbing with a little kaolin and massing with kaolin ointment. Some advertised "cures" for alcoholism are said to contain a gold salt. Doses increasing to 0.03 gramme ($\frac{1}{2}$ grain) are sometimes given.

Dose.—0.001 to 0.012 gramme ($\frac{1}{60}$ to $\frac{1}{8}$ grain).

ACIDUM BROMAURICUM.—Bromauric acid may be obtained by the action of hydrobromic acid on solution of auric bromide. On evaporation, the solution deposits large, red, flat, needle-shaped crystals, $\text{HAuBr}_4 \cdot 5\text{H}_2\text{O}$ or $\text{HAuBr}_4 \cdot 6\text{H}_2\text{O}$, which melt at about 27° . It may be recrystallised from ether or chloroform. It is decomposed by concentrated sulphuric acid at 155° into aurous bromide and bromine.

AURI CHLORIDUM.—Gold chloride usually consists of sodium chloraurate, $\text{NaAuCl}_4 \cdot 2\text{H}_2\text{O}$, which is soluble in water and ether (distinction from the potassium salt). It is much more stable than the acid and its water of crystallisation cannot be driven off without also decomposing the salt. Chlorauric acid may be obtained by dissolving gold in nitro-hydrochloric acid, adding an excess of hydrochloric acid, and evaporating the solution. It occurs in yellow crystals which deliquesce in moist air to a yellow solution. Two definite hydrates are known, $\text{HAuCl}_4 \cdot 3\text{H}_2\text{O}$ and $\text{HAuCl}_4 \cdot 4\text{H}_2\text{O}$, and it yields well defined salts. Gold chloride has properties similar to those of gold bromide and may be administered in pills compounded with kaolin ointment. It is used in making Lange's colloidal gold, a preparation used as a diagnostic reagent in the examination of cerebrospinal fluid in diseases of the central nervous system. The chloride is also used in photography. **Dose.**—0.001 to 0.012 gramme ($\frac{1}{60}$ to $\frac{1}{8}$ grain).

Preparation

Liquor Auri et Arseni Brominatus, B.P.C.—(Liq. Aur. et Arsen. Brominat.)—Brominated Solution of Gold and Arsenic. *Syn.*—Liquor Auri et Arsenii Bromidi; Liquor Auri Bromidi Arsenatus. 0.6 millilitre contains the equivalent of 0.0028 gramme of arsenic trioxide and 0.002 gramme of auric bromide; 10 minims contains the equivalent of $\frac{1}{4}$ grain of arsenic trioxide and $\frac{1}{2}$ grain of auric bromide. **Dose.**—0.3 to 0.6 millilitre (5 to 10 minims).

AURI ET SODII THIOSULPHAS

(Aur. et Sod. Thiosulph.)

Gold Sodium Thiosulphate

Synonym—Sodium Aurothiosulphate.

Gold sodium thiosulphate may be prepared by the interaction of gold chloride with a solution of sodium thiosulphate. The resulting solution is treated with alcohol and the precipitate purified by crystallisation from water. It occurs in white, crystalline needles, without

odour, and has a sweet taste. Its aqueous solution is neutral to litmus and does not precipitate proteins from solution. The dry salt is stable in dry air, and may be **stored** in sealed ampoules without undergoing decomposition. When exposed to moist air, the product is likely to decompose and become yellowish, especially if exposed to light, and it is then unsuitable for use. Dilute aqueous solutions, 1 in 100, are moderately stable and may be sterilised at 100°. More concentrated solutions are liable to decompose on heating or on exposure to light.

Very readily **soluble** in water; insoluble in alcohol.

Standard.—Gold sodium thiosulphate contains not less than 37·0 per cent. and not more than 37·6 per cent. of Au. When kept in sealed phials at 75° for twenty-four hours, it retains its colour, physical properties and solubility.

Assay.—Dissolve about 0·8 gramme, accurately weighed, in 50 millilitres of water, add 10 millilitres of N/1 sodium hydroxide and 10 millilitres of hydrogen peroxide solution (20 vols.); boil until the excess of hydrogen peroxide is decomposed, acidify with hydrochloric acid, allow the precipitate of metallic gold to coagulate, filter, wash thoroughly with boiling water, dry, ignite and weigh.

Action and Uses.—Gold sodium thiosulphate, when injected intravenously, is for the most part rapidly absorbed from the blood stream, although some remains unabsorbed for twenty-four hours or longer. It is slowly excreted from the system, partly through the alimentary tract but principally through the kidneys. It is said to exert a specific action on tubercle bacilli, but since its action is not strictly in accordance with the generally accepted ideas of a chemotherapeutic agent, its use is more or less empirical. In the treatment of pulmonary tuberculosis it is most satisfactory in the early, moderately advanced and exudative type of case, although old, chronic cases may benefit if treatment is carefully carried out. Following the administration of gold sodium thiosulphate the sputum rapidly becomes free from tubercle bacilli and the patient shows an increase in weight and improvement in general condition. As an adjunct to collapse therapy, gold sodium thiosulphate has proved useful in selected cases since it clears up the "better" lung in bilateral cases. Tuberculous pleurisy has been treated with some success.

Gold sodium thiosulphate is generally contra-indicated when there is extensive bilateral fibrosis or extreme cachexia since it is likely to accelerate the progress of the disease. Febrile cases are also somewhat difficult to treat, but a good response may be obtained from small and carefully graduated doses. Intestinal tuberculosis, surgical tuberculosis and tuberculous meningitis are not generally benefited by the administration of this drug. Distinctly favourable results have been reported in lupus erythematosus, but patients with lupus vulgaris do not appear to be greatly benefited by the drug. Large doses (about 1 gramme) have been found effective in the treatment of syphilis, but the reactions that may occur are a drawback to its wider application.

It may, however, prove useful in cases where arsenic compounds and mercury are not well tolerated. Although only limited experience has been obtained with this drug in the treatment of leprosy, considerable improvement has been reported in a number of cases, particularly when used in conjunction with local treatment by carbon dioxide snow. Good results have been reported from the use of gold sodium thiosulphate in the treatment of rheumatic disease.

The administration of gold sodium thiosulphate, especially in large doses, is liable to be attended with reactions which are manifested chiefly by a rise in temperature, albuminuria, and skin reactions, such as localised rashes, papular eruptions or a generalised exanthema. To counteract these symptoms, solution of sodium thiosulphate should be injected intravenously. Even moderate doses of gold sodium thiosulphate may produce albuminuria and this should always be looked for and regarded as a warning to discontinue treatment until the urine is free from albumin. On this account treatment should be carried out with the patient under regular observation, institutional rather than ambulatory treatment being preferable. Gold sodium thiosulphate is **administered** by intravenous injection in solutions not exceeding 5 per cent. w/v in strength. Where intravenous injection presents any difficulty, intramuscular injection can be resorted to, but in this case the strength of the solution should be 3 per cent. in sterilised water, or preferably 5 or 10 per cent. in oily suspension. It should never be given by subcutaneous injection. It is generally considered advisable to commence with a dose of from 0.025 to 0.1 gramme ($\frac{2}{5}$ to $1\frac{1}{2}$ grains), gradually increasing at intervals of about seven days up to a maximum of about 1 gramme (15 grains) for males, or 0.75 gramme (11 grains) for females, or to the limit of tolerance, which may be less than these amounts. For children, the maximum is 0.5 gramme (8 grains). In the treatment of tuberculosis, the maximum tolerated amount can be repeated until a total of 5 or 6 grammes (75 or 90 grains) has been given; after an interval of three or four months a further course of doses can be given. A suitable initial dose in the treatment of rheumatism is 0.1 gramme ($1\frac{1}{2}$ grains), increased by 0.05 or 0.1 gramme at intervals of two or three days, but not more than 0.6 gramme (10 grains) should be administered in one week. Solutions for **injection** may be prepared by aseptic methods.

Dose.—0.025 to 1 gramme ($\frac{2}{5}$ to 15 grains), by injection.

AZORUBRUM

(Azorub.)

Bordeaux B

Bordeaux B (Colour Index No. 88) is the sodium salt of α -naphthalene-azo- β -naphthol-3:6-disulphonic acid and may be prepared by coupling

diazotised α -naphthylamine with β -naphthol-3 : 6-disulphonic acid. It occurs as a brown powder. The colour of the aqueous solution is unaltered on the addition of hydrochloric acid, becomes yellowish-brown with sodium hydroxide and blue with sulphuric acid, the colour changing to magenta-red on dilution. It is reduced by hydrosulphite, the colour being discharged.

Soluble in water, giving a magenta-red solution; moderately soluble in alcohol, forming a bluish-red solution.

Standard.—Bordeaux B leaves not more than 65 per cent. of sulphated ash. Arsenic limit, 30 parts per million. Lead limit, 50 parts per million. Dissolve the sulphated ash from 1 gramme in 20 millilitres of water and 2 millilitres of dilute hydrochloric acid, and add 1 millilitre of potassium ferrocyanide solution; no precipitate is obtained (limit of zinc).

Uses.—Bordeaux B is practically unaffected by dilute acids and alkalis, or by exposure to sunlight. Owing to the greater permanence of the colour produced, it is extensively used in place of cochineal and cudbear as a colouring agent for medicines and foodstuffs. It may be used in the form of *Liquor Azorubri*, of which about 5 minims is usually sufficient for each fluid ounce of liquid.

Preparation

Liquor Azorubri, B.P.C.—(*Liq. Azorub.*)—Solution of Bordeaux B. *Syn.*—*Liquor Ruber.* Bordeaux B, 1 per cent. w/v, in glycerin and chloroform water.

BALSAMUM PERUVIANUM

(*Bals. Peruv.*)

Balsam of Peru

Balsam of Peru is obtained from the trunk of *Myroxylon Pereiræ* (Royle) Klotzsch (Fam. Leguminosæ), a tree growing in the forests of San Salvador in Central America. The formation of the balsam, which is not a normal secretion of the tree, is induced by gently beating the bark, which is then removed, and subsequently scorching the trunk. As the balsam exudes it is soaked up by rags with which the wounded places are covered; the rags are pressed and the crude balsam so obtained purified by boiling with water. The drug is exported chiefly from Acajutla and Belize to New York and Hamburg.

Balsam of Peru occurs as a dark brown, viscid liquid which is, transparent and reddish-brown when viewed in thin layers. It has an agreeable, balsamic odour recalling that of vanillin, and a bitter, acrid taste with a persistent after-taste, causing a burning sensation in the throat. It is free from stringiness or stickiness. The specific gravity varies from 1.140 to 1.170. The commoner adulterants such as alcohol,

kerosene, fixed oil, turpentine, copaiba, etc., lower the specific gravity perceptibly. Balsam of Peru is also frequently adulterated with artificial esters such as benzyl benzoate; such samples usually have a high proportion of balsamic esters and a low saponification value.

Balsam of Peru **contains** from 53 to 66 per cent. of a colourless, aromatic, oily liquid and about 28 per cent. of a dark resin. The liquid portion, sometimes called "cinnamein," consists of a mixture of benzyl benzoate and benzyl cinnamate in varying proportions, the former usually predominating; the resin consists of a resin alcohol, peruresinotannol, combined with cinnamic acid and a little benzoic acid. The drug contains, in addition, an alcohol, peruvial, which possesses a sweet odour and taste, together with traces of vanillin and free cinnamic acid. Balsam of Peru of good quality may contain not more than 50 per cent. of balsamic esters.

Soluble in alcohol (1 in 1, the addition of more alcohol causing the solution to become turbid), and chloroform; partially soluble in ether and glacial acetic acid. Water shaken with the balsam removes only traces of cinnamic acid.

Standard, B.P.—Balsam of Peru contains not less than 53 per cent. of balsamic esters, the saponification value of which is not less than 235. It complies also with tests for the absence of fatty oils and of benzaldehyde and turpentine.

Action and Uses.—Balsam of Peru is an antiseptic expectorant, but is seldom used internally. Externally, it acts as an antiseptic and parasiticide, especially in scabies. It is sometimes used as an antiseptic for ulcerated surfaces, such as bedsores, and for chilblains. For external application it is usually employed in the form of ointment, and is sometimes applied in the treatment of skin diseases, undiluted or mixed with an equal quantity of castor oil. Suppositories may be prepared with oil of theobroma and sufficient white wax to counteract the softening effect of the balsam.

Dose.—0.3 to 1 millilitre (5 to 15 minims).

Preparations

Suppositorium Bismuthi Subgallatis Compositum, B.P.C.—(Supp. Bism. Subgall. Co.)—Compound Bismuth Subgallate Suppository. *Syn.*—Suppositorium Bismuthi et Resorcini Compositum; Compound Bismuth and Resorcin Suppository. Each suppository contains 3 grains of bismuth subgallate, 1 grain of resorcinol, 2 grains of zinc oxide and 1 minim of balsam of Peru.

Unguentum Peruvianum, B.P.C.—(Ung. Peruv.)—Balsam of Peru Ointment. Balsam of Peru, 12.5 per cent., in simple ointment.

Unguentum Zinci cum Balsamo Peruviano, B.P.C.—(Ung. Zinc. c. Bals. Peruv.)—Zinc Ointment with Balsam of Peru. Balsam of Peru, about 11 per cent., in ointment of zinc oxide and ointment of boric acid.

BALSAMUM TOLUTANUM

(Bals. Tolu.)

Balsam of Tolu*Synonym*—Tolu.

Balsam of tolu is obtained from the trunk of *Myroxylon toluifera* H.B. and K. (Fam. Leguminosæ), a tree indigenous to New Granada. The balsam exudes from incisions made in the trunk and is collected in gourds, being afterwards transferred to skins and finally exported in tins. It is imported as a soft, tenacious, resinous substance which becomes harder on keeping and is brittle in cold weather. A small piece, warmed and pressed between two pieces of glass, forms a transparent, yellowish-brown film, which exhibits scattered crystals of cinnamic acid when examined under a lens. The balsam has a fragrant odour, and an aromatic, slightly acid taste. When a small piece is boiled with water, the filtered aqueous solution evolves the odour of benzaldehyde on warming with potassium permanganate solution. An alcoholic solution of balsam of tolu has an acid reaction and gives a green colour on the addition of ferric chloride solution.

Balsam of tolu **contains** 12 to 15 per cent. of free cinnamic acid, about 8 per cent. of free benzoic acid, a trace of vanillin and about 7·5 per cent. of an oily liquid consisting of benzyl benzoate with a little benzyl cinnamate. The resin, of which the balsam contains about 80 per cent., yields, on saponification, the alcohol, tolueresinotannol, cinnamic acid, and a little benzoic acid. Good fresh balsam of tolu yields, when distilled with water, from 1·5 to 3·0 per cent. of a very fragrant volatile oil.

Soluble in alcohol, benzene, chloroform, ether and glacial acetic acid; partially soluble in carbon disulphide, the soluble portion consisting chiefly of cinnamic acid; it is also partially soluble in sodium hydroxide solution.

Standard, B.P.—Balsam of tolu contains not less than 19 per cent. and not more than 25 per cent. of free balsamic acids and not less than 35 per cent. and not more than 50 per cent. of total balsamic acids, both being calculated on the dry, alcohol-soluble matter. Alcohol-insoluble matter, not more than 4 per cent. Loss on drying in a thin layer in a vacuum over sulphuric acid, not more than 4 per cent. Acid value, 97 to 160; ester value, 47 to 95; saponification value, 170 to 224; all being calculated on the dry, alcohol-soluble matter. It complies also with a test for absence of colophony.

Action and Uses.—Balsam of tolu is an antiseptic expectorant. Its preparations are employed in cases in which the mucus is tenacious and removed with difficulty by coughing. Mixtures containing tincture of tolu require mucilage of acacia to suspend the resin in a diffusible form.

Dose.—0·3 to 1 gramme (5 to 15 grains).

Preparations

Liquor Tolutanus, B.P.C.—(Liq. Tolu.)—Solution of Tolu. Balsam of tolu, 1 in 10, with sucrose, alcohol (90 per cent.) and distilled water. One volume diluted with seven volumes of syrup yields a syrup of tolu which is more aromatic than Syrupus Tolutanus.

Syrupus Tolutanus, B.P.—(Syr. Tolu.)—Syrup of Tolu. *Syn.*—Syrup of Balsam of Tolu. It contains the active constituents of 2·5 per cent. w/w of balsam of tolu, with sucrose and distilled water. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Tinctura Tolutana, B.P.—(Tinct. Tolu.)—Tincture of Tolu. *Syn.*—Tincture of Balsam of Tolu. Balsam of tolu, 10 per cent. w/v, in alcohol (90 per cent.). Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

BAPTISIA

(Baptis.)

Baptisia

Synonym.—Wild Indigo Root.

Baptisia consists of the dried root of *Baptisia tinctoria* R. Br. (Fam. Leguminosæ), indigenous to Canada and the United States of America. It is collected in the autumn.

The root shows a branched, knotty crown, marked by stem-scars and measuring over all from about 4 to 8 centimetres. To the crown are attached a few sub-cylindrical and slightly tapering roots from about 0·5 to 1·5 centimetres thick and up to about 40 centimetres long. Externally, the drug is brown and longitudinally wrinkled, the older pieces being somewhat warty and scaly, and bearing a few long, wiry, branching rootlets. The fracture is fibrous and the smoothed transverse surface exhibits a thick, greyish-white bark, which easily separates from the yellowish-white, radiate, porous wood. The odour is slight, and the taste of the bark is bitter and slightly acid.

The diagnostic **microscopical** characters are the numerous starch grains, simple or compound with 2 to 4 components, individual grains being up to 16 microns in diameter; numerous pitted vessels, up to 90 microns wide, from the xylem; the thick-walled, more or less lignified phloem fibres; groups of starch-bearing parenchyma; the cork cells with brownish and slightly lignified walls.

Baptisia **contains** the alkaloid, cytisine, the glycosides, baptin and baptisin (about 6 per cent.), and a crystalline, purgative principle. The ash is about 2·5 per cent. and the acid-insoluble ash about 0·5 per cent.

Action and Uses.—Baptisia has laxative properties and has been administered as a decoction. The tincture is used in the preparation of Liquor Thymolis Compositus.

Preparation

Tinctura Baptisiz, B.P.C.—(Tinct. Baptis.)—Tincture of Baptisia. 1 in 10.

BARBITONUM

(Barbiton.)

Barbitone*Synonym*—Barbital.

Barbitone, or diethylmalonylurea, is 5:5-diethylbarbituric acid and may be prepared by the condensation of urea with ethyl diethylmalonate. It occurs as a white, odourless, crystalline powder, with a slightly bitter taste. The saturated aqueous solution has an acid reaction and on the addition of nitric acid followed by a few drops of Millon's reagent, a white, gelatinous precipitate is produced, which is soluble in excess of the reagent. When heated with solid sodium hydroxide or with a strong aqueous solution, barbitone is decomposed with evolution of ammonia. It is soluble in aqueous solutions of alkali hydroxides and carbonates, with formation of alkali derivatives.

Soluble in water (1 in about 170), boiling water (1 in 12), alcohol (1 in 8.5), ether, chloroform and acetone.

Standard, B.P.—Barbitone has a melting-point of 189° to 192°. Ash, not more than 0.05 per cent. It complies also with limit tests for readily carbonisable substances and for neutral and basic substances.

Action and Uses.—Barbitone is a hypnotic which is said to act only upon the central nervous system, and has been found especially suitable for use in nervous insomnia and in insomnia associated with cardiac disease. In ordinary doses it does not affect the medullary centres to an appreciable degree and, therefore, blood pressure and respiration are not influenced. Barbitone belongs to the group of indifferent hypnotics, which owe their action to their physical property of relative solubility in brain-lipoid and insolubility in water. It is excreted slowly, so that cumulation may occur; eight grains requires three or four days for complete excretion. Regular administration, like that of other cumulative drugs, leads to sudden poisonous symptoms, such as rash, sickness, headache and delirium. In acute poisoning, coma and all the symptoms of collapse may result, often with rise of temperature, and may be followed by broncho-pneumonia. The dose of 0.3 gramme (5 grains) is ordinarily sufficient; poisonous symptoms have been noticed even with doses of 0.6 gramme (10 grains). The bowels and kidneys should be functioning properly when barbitone is administered because it is excreted slowly. It should be given with caution in cardio-renal affections. Barbitone is of value in sea-sickness and has been given as a sedative before ether or chloroform anæsthesia.

Many derivatives of barbituric acid are used for the same purpose as barbitone, but, generally speaking, they are more powerful and, therefore, more potentially dangerous. These hypnotics in ordinary doses are of little use when sleeplessness is due to pain. In such cases they are generally combined with drugs such as amidopyrine and acetylsalicylic acid, which possess analgesic properties. Barbitone is best

administered in cachets, swallowed with a draught of hot liquid. In cases of **poisoning** by barbitone, which is generally the result of cumulation, the stomach should be washed out with warm water, strychnine in full doses, adrenaline, or pituitary (posterior lobe) extract injected hypodermically, and the usual means taken to combat collapse and ensure efficient respiration. If the coma is prolonged, food should be given by stomach tube, and dextrose-saline administered by the rectum. Lumbar or cisternal puncture, and drainage to remove the poison from the brain may be necessary, especially if pneumonia has commenced.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

Preparation

Tabellæ Barbitoni et Amidopyrinæ, B.P.C.—(Tab. Barbiton. et Amidopyrin.)—Tablets of Barbitone and Amidopyrine. Each tablet contains 2 grains of barbitone and 4 grains of amidopyrine. **Dose.**—1 tablet.

BARBITONUM SOLUBILE

(Barbiton. Solub.)

Soluble Barbitone

$C_8H_{11}O_3N_2Na$ - 206.1

Synonyms—Soluble Barbital; Barbitone-Sodium.

Soluble barbitone is the monosodium derivative of barbitone and may be prepared by the interaction of barbitone and sodium hydroxide. It occurs as a white, odourless, crystalline powder with a bitter taste. The aqueous solution has an alkaline reaction and on the addition of dilute acids, barbitone is precipitated. Soluble barbitone should be **stored** in well-closed containers.

Soluble in water (1 in about 6); slightly soluble in alcohol (90 per cent.); insoluble in ether and chloroform.

Standard, B.P.—Soluble barbitone contains not less than 97 per cent. of $C_8H_{11}O_3N_2Na$. It complies also with limit tests for free barbitone and for neutral and basic substances.

Action and Uses.—Soluble barbitone has properties similar to those of barbitone, but its action is claimed to be more rapid owing to its greater solubility. For this reason, it has been **administered** rectally (1 in 20 solution) and hypodermically (1 in 10 solution). Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. In cases of **poisoning**, the procedure outlined under Barbitonum should be followed.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

BARI CARBONAS

(Barii Carb.)

Barium Carbonate

Barium carbonate exists in the natural state as the mineral witherite, and may be obtained by mixing aqueous solutions of barium nitrate or barium chloride and sodium carbonate. It occurs as a white, dense, soft powder which should be free from grittiness.

Insoluble in water and alcohol; completely soluble in dilute hydrochloric acid.

Action and Uses.—Barium carbonate is used for the destruction of rats and mice. It exerts a corrosive action upon the intestinal mucous membrane, and excites intense thirst so that the rodents search for water and finally leave infested buildings. From 1.5 to 2 grains of barium carbonate is sufficient to kill a rat. The bait should be freshly prepared; it can be made by mixing equal parts of barium carbonate and oatmeal, sweetening with a little sugar and making into a paste with tallow or dripping. Oil of anise is sometimes added as a flavouring agent. The bait should be laid out of the way of domestic animals. Barium carbonate is soluble in the gastric secretion and the chloride formed is a powerful poison. On no account should barium carbonate be administered for purposes of X-ray diagnosis. In cases of **poisoning** by barium salts, zinc sulphate may be given as an emetic, or the stomach pump used, followed by sodium sulphate in 1 ounce doses; warmth should be applied and stimulants given freely.

BARI CHLORIDUM.—Barium chloride, $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$, may be prepared from barium carbonate or from witherite. It occurs in the form of colourless, trimetric plates or glistening scales, odourless, non-efflorescent and having an unpleasant, bitter, sharp saline taste. The aqueous solution is neutral. The chloride loses its water of crystallisation at 100° , but takes it up again in moist air. It is soluble in water (1 in 2.5), but insoluble in alcohol. Barium chloride has a marked stimulant action on all forms of muscle tissue and raises the blood pressure by constricting the vessels. It is a very powerful drug and very apt to cause poisoning, but has been given in doses of up to 2 grains. It is used principally as a chemical reagent.

BARI SULPHAS

(Barii Sulphas)

Barium Sulphate

Synonyms—Barium Sulphate (X-ray); Barii Sulphas Purificatus.

Barium sulphate may be prepared by double decomposition between a soluble barium salt and a soluble sulphate. The precipitate is washed free from soluble barium compounds and dried. It occurs as a heavy,

white, amorphous powder. The salt is slightly soluble in boiling hydrochloric acid, and on diluting and filtering the cold solution, the filtrate gives reactions both for barium and for sulphate. It is also slightly soluble in nitric acid and in solutions of many salts.

Insoluble in water.

Standard, B.P.—Barium sulphate loses, on drying at 110° , not more than 2 per cent. of its weight. Arsenic limit, 1 part per million. It complies also with limit tests for acid-soluble matter, soluble barium compounds, copper, lead, mercury, tin and zinc, acid or alkali, phosphate, and for sulphide, sulphite and thiosulphate.

Action and Uses.—Barium sulphate has replaced bismuth compounds in X-ray examination of the alimentary tract, and for the purpose of outlining granulation sinuses. It passes through the body unchanged. Since barium is the most poisonous of the alkaline-earth metals, it is essential that pure barium sulphate be used. When given by the mouth it is mixed with milk or a farinaceous food, and suitably flavoured and sweetened. For examination of the colon, X-ray photographs are taken when the barium meal reaches the large gut, or after an enema containing barium sulphate has been administered. The enema for this purpose may be prepared with barium sulphate, 8 ounces, arrowroot, $\frac{3}{4}$ ounce, compound powder of tragacanth, $\frac{1}{4}$ ounce, and water, sufficient to produce 60 fluid ounces. Barium sulphate, administered by the mouth, has been used in the treatment of ulcerative colitis; it acts as a protective to the inflamed ulcerated areas, and serves to check diarrhœa.

Preparation

Pulvis Barii Sulphatis Compositus, B.P.C.—(Pulv. Barii Sulphatis Co.)—Compound Powder of Barium Sulphate. *Syn.*—Barium Meal; Shadow Meal. It contains 75 per cent. of barium sulphate. Dose.—120 to 240 grammes (4 to 8 ounces), mixed immediately before use with a sufficient quantity of boiling water poured directly on the powder.

BARYTA SULPHURATA

(Baryt. Sulphur.)

Sulphurated Baryta

Synonym—Barium Sulphide.

Sulphurated baryta is a mixture containing barium sulphide ($\text{BaS} = 169.4$) and barium sulphate and may be obtained by igniting a mixture of barium sulphate and carbon. It occurs as a greyish-white or yellow powder, the latter containing free sulphur. In moist air it becomes converted into barium carbonate and thiosulphate, hydrogen sulphide being evolved. On ignition in air, it is converted into barium sulphate. It should be **stored** in well-stoppered bottles.

Partially **soluble** in water with decomposition, yielding barium hydroxide and hydrosulphide.

Standard.—Sulphurated baryta contains not less than 60 per cent. of BaS.

Assay.—Mix about 1 gramme, accurately weighed, with 50 millilitres of boiling water, and titrate with ammoniacal zinc solution until no black or brown colour is obtained when a drop of the solution is added to a drop of alkaline lead indicator; each millilitre of the ammoniacal zinc solution is equivalent to 0.02 gramme of BaS.

Action and Uses.—Sulphurated baryta is employed **externally** as a depilatory, being usually mixed with an equal weight, or twice its weight, of starch, or a mixture of starch and zinc oxide, with or without powdered soap; the powder should be mixed with sufficient water to form a thin paste immediately before application; after five or ten minutes the application is scraped off, and the part washed with warm water. The skin is reddened, temporarily, by this treatment. Sulphurated baryta is very **poisonous** and on no account should be supplied when “Barii Sulph.” is ordered for X-ray examinations, the innocuous Barii Sulphas being intended by such direction.

BASSIA

(Bassia)

Bassia

Synonyms—Mowrah; Mowra; Mahua; Illipe.

Bassia consists of the seeds of *Bassia latifolia* Roxb. from the Central Provinces, Chota Nagpur and Western India, *B. longifolia* Linn. from Hyderabad and Madras, and *B. butyracea* Roxb. (Fam. Sapotaceæ) from the sub-Himalayan districts.

The seeds of *B. latifolia* are about 2 to 4 centimetres long, 1 to 1.5 centimetres wide and 0.7 to 1.0 centimetre thick, the average weight of one seed being about 1.0 gramme. They are exalbuminous, elongated-ovoid, pointed at one end and rounded at the other. The testa is smooth, glossy, and cinnamon-brown in colour, except for one edge along which runs the wide, greyish hilum. The seeds of *B. longifolia* and *B. butyracea* closely resemble those of *B. latifolia*.

Bassia **contains** from 50 to 55 per cent. of fixed oil, which is semi-solid and pale yellow, with an unpleasant taste and a characteristic odour. After bleaching in the sun and air, the oil forms a food-stuff known as mowrah butter. The seeds also contain a poisonous saponin, mowrin, which is found in the cake after the expression of the oil. This cake, when powdered, is dark chocolate-brown in colour and is known as mowrah meal.

Uses.—The fixed oil expressed from the seeds is used in India as

an edible fat and, after hardening, which is easily effected, it is used in the manufacture of margarine and as a substitute for cocoa butter in chocolate. Mowrah cake is used in India as a substitute for soap, and as a fish-poison. Mowrah meal, in a very finely powdered condition, is used as a worm-killer, for which purpose it is sprinkled over the ground in the proportion of about 4 ounces to the square yard, and followed by thorough watering.

BEBERINÆ SULPHAS

(Beberin. Sulph.)

Beberine Sulphate

Synonym—Bebeerine Sulphate.

Beberine sulphate may be prepared from commercial beberine, a mixture of alkaloids obtained from *Nectandra* Cortex (Bebeeru Bark) which is the bark from the stem of *Nectandra Rodiaci* Hook. (Fam. Lauracæ), a tree indigenous to British Guiana. It is obtained from the mixed alkaloids by dissolving the latter in alcohol, neutralising the solution with dilute sulphuric acid, evaporating the liquid on a water-bath to a syrupy consistence, spreading this on glass plates, and scaling. It occurs in brown, translucent scales with a very bitter taste, and contains about 30 per cent. of beberine associated with other alkaloids and much colouring matter.

Soluble in water (about 1 in 1); sparingly soluble in alcohol.

Action and Uses.—Beberine sulphate is an aromatic bitter, and is used as a substitute for quinine because of its antipyretic and tonic properties. It has been given in dysmenorrhœa, menorrhagia and leucorrhœa. It is **administered** in solution in water, usually with a mineral acid, or in pills.

Dose.—0·06 to 0·3 gramme (1 to 5 grains).

BELA

(Bela)

Bael

Synonyms—Belæ Fructus; Bael Fruit; Indian Bael; Bengal Quince.

Bael consists of the fresh or dried, half-ripe fruit of cultivated trees of *Aegle Marmelos* Correa. (Fam. Rutacæ), a tree indigenous to India. In India the pulp is used while fresh; the dried fruit is exported entire or in transverse slices or quarters.

The fruit is a sub-globose berry from 7 to 10 centimetres in diameter. Externally, it has a yellowish-brown, smooth, or slightly granular, hard rind, 2 to 3 millimetres thick, bearing a circular scar at the point of

attachment of the peduncle. When cut transversely the rind appears reddish and is seen to enclose from 10 to 15 carpels, each containing several oblong, flat, hairy seeds embedded in a pale reddish pulp, which usually adheres to the rind. The pulp becomes very hard on drying.

Bael **contains** mucilage and pectin in the pulp. Ripe fruits differ from the unripe in yielding the tannin reaction with ferric chloride solution and also in possessing a distinct aroma.

Substitutes.—Substitutes for bael occur at times, including mangosteen fruits, *Garcinia Mangostana* Linn. (Fam. Guttiferæ), which are distinguished by the darker rind, to which the pulp does not firmly adhere, and by the wedge-shaped radiate stigmas, and the wood apple, *Feronia elephantum* Correa. (Fam. Rutaceæ), which is five-lobed, one-celled, and has a rough exterior.

Action and Uses.—Bael is a mild astringent and is used in India as a popular remedy for diarrhœa and dysentery. The fresh pulp may be eaten, or the drug may be **administered** in the form of Extractum Belæ Liquidum. The use of the extract is not followed by constipation and is particularly suitable for children.

Preparation

Extractum Belæ Liquidum, B.P.C.—(Ext. Belæ Liq.)—Liquid Extract of Bael. 1 in 1. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

This liquid extract, prepared without the chloroform, was included in the British Pharmacopœia, 1914

BELLADONNÆ FOLIUM

(Bellad. Fol.)

Belladonna Leaf

Synonym—Deadly Nightshade Leaf.

Belladonna leaf consists of the dried leaves and tops of *Atropa Belladonna* Linn. (Fam. Solanaceæ), collected when the plant is in flower. The plant is a tall, branching, herbaceous perennial, widely distributed over Central and Southern Europe and cultivated in England. It should be **stored** in a dry place.

The leaves are thin, brittle, and of a pale yellowish-green colour; they are alternate and upon the upper stems are arranged in pairs, each consisting of a larger and a smaller leaf. They are simple and have a short petiole up to about 4 centimetres long; the lamina is usually from 5 to 25 centimetres long and 2.5 to 12 centimetres broad, broadly ovate, with an entire margin and an acuminate apex; the surface is only slightly hairy and the lamina is somewhat decurrent down the petiole. The flowers are borne singly upon short, drooping pedicels arising in the axils of the pairs of leaves; the campanulate corolla is livid purple, about 2.5 centimetres long and 1.2 centimetres wide, and has 5 small reflexed lobes; there are 5 epipetalous stamens and a superior, bilocular ovary

with numerous ovules attached to an axile placenta. The fruit is a green to dark purplish-black berry containing numerous small, brown, reticulate seeds. The odour is slight, and the taste unpleasant and bitter.

The diagnostic **microscopical** characters are the epidermal cells with wavy radial walls and a striated cuticle; the cruciferous type of the stomata on both surfaces; the single layer of palisade parenchyma; the idioblasts of the mesophyll and stem parenchyma, containing microsphenoidal crystals of calcium oxalate; the perimedullary phloem of the midrib and of the stem; the large xylem vessels; the pericyclic and xylem fibres of the stem; the occasional trichomes of two kinds, uniseriate covering trichomes, and glandular trichomes of various forms.

Belladonna leaf **contains** the alkaloid hyoscyamine and possibly atropine, the total quantity present in dried leaves of good quality being about 0.4 to 1.0 per cent., the greater part of which is hyoscyamine. The leaves also contain β -methyl α -sculetin (scopoletin, chrysotropic acid), and it is possible that they may contain minute quantities of other alkaloids (belladonnine, etc.), but not in sufficient quantity to contribute to the physiological action. Further constituents are small amounts of the volatile bases, pyridine, N-methylpyrrolidine, N-methylpyrrolidine and a diamine with a pyrrol nucleus.

Substitutes and Adulterants.—The leaves of *Phytolacca decandra* Linn. and of other species of *Phytolacca* (Fam. Phytolaccaceæ), of *Scopolia carniolica* Jacq. (Fam. Solanaceæ) and of *Ailanthus glandulosa* Desf. (Fam. Simarubaceæ) occur at times as substitutes for belladonna leaf. They are best distinguished by their microscopical features; phytolacca leaves contain idioblasts with acicular raphides of calcium oxalate; scopolia leaves possess stomata on the under surface only and the idioblasts with microsphenoidal crystals of calcium oxalate are much fewer than in belladonna leaf, while the fruit, a nearly spherical pyxis, is usually present; ailanthus leaves have cluster-crystals of calcium oxalate near the veins.

Standard, B.P.—Belladonna leaf contains not more than 2 per cent. of foreign organic matter, not more than 20 per cent. of its stem and not more than 1 per cent. of its stem having a width greater than 5 millimetres, and not less than 0.3 per cent. of the alkaloids of belladonna leaf, calculated as hyoscyamine. Ash, not more than 15 per cent. Acid-insoluble ash, not more than 3 per cent.

Belladonna leaf, in powder, contains the constituents and possesses the diagnostic microscopical characters of *Belladonnæ Folium*, and complies with the limits for alkaloids, ash and acid-insoluble ash of the unground drug. When powdered belladonna leaf is prescribed, the standardised powder, *Belladonna Pulverata*, must be used.

Action and Uses.—Preparations of belladonna are used to check excessive secretion and to allay inflammation, particularly in secretory glands. The drug is a powerful anti-spasmodic in intestinal colic and in spasmodic asthma; given with purgatives, it depresses the inhibitory nerves of the intestines and allays griping. Belladonna is well tolerated by children and is given in large doses in whooping cough, urinary incontinence and false croup. For its action on the circulation it is given in the collapse of pneumonia, typhoid fever, and other acute

diseases. It is of value in acute sore throat and relieves local inflammation and congestion. Belladonna decreases gastric secretion and when this action is desired it should not be given just before or after meals. The glycerin of belladonna or the plaster is applied externally to allay pain, and as an antilactagogue.

Belladonna leaf is **administered** as Belladonna Pulverata, but is used principally in the form of dry extract and green extract and, in mixtures, in the form of tincture. Occasionally the leaves are employed as an ingredient of cigarettes for spasmodic asthma, but their use should not be encouraged. Extractum Belladonnæ Viride is commonly prescribed with purgatives in pill form, to diminish their tendency to cause griping, with camphor and quinine for nasal catarrh and with camphor or the valerianates as a sedative. For external use, the green extract is softened with warm water and spread upon leather for local application, or used in the form of Glycerinum Belladonnæ to allay pain or arrest glandular secretion. The green extract is sometimes specified for use in suppositories; it must be rubbed to a smooth consistence with a few drops of warm water before mixing with the melted fat; excess of heat separates the chlorophyll. In cases of **poisoning** by belladonna or by the alkaloids of belladonna the procedure described under Atropina should be followed.

Preparations

Belladonna Pulverata, B.P.—(Bellad. Pulverat.)—Powdered Belladonna Leaf. *Syn.*—Pulvis Belladonnæ. Belladonna leaf reduced to fine powder and adjusted with exhausted belladonna leaf to contain 0·3 per cent. of alkaloids, calculated as hyoscyamine (limits, 0·28 to 0·32). Ash, not more than 15 per cent. 0·2 gramme contains about 0·0006 gramme, and 3 grains contains about $\frac{1}{100}$ grain of alkaloids. Dose.—0·03 to 0·2 gramme ($\frac{1}{2}$ to 3 grains).

Pulvis Belladonnæ I.A. is adjusted with rice starch to contain 0·3 per cent. of total alkaloids.

Emplastrum Belladonnæ Viride, B.P.C.—(Emp. Bellad. Vir.)—Green Belladonna Plaster. It contains dry extract of belladonna equivalent to 0·25 per cent. of the alkaloids of belladonna leaf, with chlorophyll and rubber adhesive plaster.

Extractum Belladonnæ Siccum, B.P.—(Ext. Bellad. Sicc.)—Dry Extract of Belladonna. It is prepared with alcohol (70 per cent.) and adjusted with belladonna leaf in fine powder to contain 1 per cent. of the alkaloids of belladonna leaf, calculated as hyoscyamine (limits, 0·95 to 1·05); 0·06 gramme contains about 0·0006 gramme and 1 grain contains about $\frac{1}{100}$ grain of alkaloids. It should be stored in small, wide-mouthed, well-closed containers in a cool place. Dose.—0·015 to 0·06 gramme ($\frac{1}{4}$ to 1 grain).

Extractum Belladonnæ I.A. is prepared with alcohol (70 per cent.), evaporation being conducted at temperatures below 50°, and contains not less than 1·3 per cent. of total alkaloids.

Extractum Belladonnæ Viride, B.P.C.—(Ext. Bellad. Vir.)—Green Extract of Belladonna. A soft extract containing from 0·95 to 1·05 per cent. of the alkaloids of belladonna, calculated as hyoscyamine; 0·06 gramme contains about 0·0006 gramme, and 1 grain contains about $\frac{1}{100}$ grain of alkaloids. Dose.—0·016 to 0·06 gramme ($\frac{1}{4}$ to 1 grain).

Green extract of belladonna replaces the unstandardised Extractum Belladonnæ Viride, B.P. 1898.

Glycerinum Belladonnæ, B.P.C.—(Glycer. Bellad.)—Glycerin of Belladonna. Green extract of belladonna, 1 in 2 w/w, with distilled water and glycerin.

Tinctura Belladonnæ, B.P.—(Tinct. Bellad.)—Tincture of Belladonna. It is prepared by percolation with alcohol (70 per cent.) and contains 0.03 per cent. w/v of the alkaloids of belladonna leaf, calculated as hyoscyamine (limits, 0.028 to 0.032); 2 millilitres contains 0.0006 gramme and 30 minims contains about $\frac{1}{160}$ grain of alkaloids. Dose.—0.3 to 2 millilitres (5 to 30 minims).

Tinctura Belladonnæ I.A. is prepared with alcohol (70 per cent.) and contains not less than 0.03 per cent. of total alkaloids. Sirupus Belladonnæ I.A. contains 5 per cent. of Tinctura Belladonnæ I.A.

BELLADONNÆ RADIX

(Bellad. Rad.)

Belladonna Root

Belladonna root is the dried root of *Atropa Belladonna* Linn. (Fam. Solanaceæ), a large, branching, herbaceous perennial, growing freely upon calcareous soils throughout Central and Southern Europe, and cultivated in England. The root is collected in the autumn when about three to four years old, the larger roots being divided longitudinally.

The root is simple or occasionally branched; it is sub-cylindrical, and occurs entire or longitudinally split, the pieces being about 10 to 30 centimetres long and up to about 4 centimetres wide at the crown. Externally it is covered with a thin, pale, greyish-brown, longitudinally wrinkled cork, and breaks with a short fracture. The smoothed, transversely cut surface is whitish to brownish in colour and shows a dark cambium line separating a narrow bark, which is devoid of fibres, from a parenchymatous xylem containing scattered groups of vessels, which are more numerous and inconspicuously radiate just within the cambium. The crown of the root shows a central pith and a markedly radiate xylem.

The diagnostic **microscopical** characters are the abundant parenchyma containing starch in simple and occasional compound grains, 15 to 20 or up to 30 microns in diameter; the idioblasts containing microspheonoidal crystals of calcium oxalate; the large vessels with closely arranged bordered pits; thin-walled xylem fibres; patches of cork cells; the absence of phloem fibres and stone cells.

Belladonna root **contains** the alkaloids hyoscyamine and atropine. Hyoscyamine exists in the larger proportion and it is doubtful whether the crude drug contains atropine, it being probable that in the process of extraction part of the hyoscyamine is converted into atropine. Traces of hyoscyne are also said to be present, as well as the crystalline, fluorescent substance, β -methylæsculetin. The total amount of alkaloid in the root varies from about 0.3 to 0.8 per cent.

Substitutes and Adulterants.—Indian belladonna root, collected in Kashmir, has been referred to *A. lutescens* Jacq. Some of the belladonna root produced

in India is obtained from *A. Belladonna* Linn. Poke root (see *Phytolacca*) is sometimes substituted for belladonna and may be detected by its characteristic structure and, in powder, by the presence of acicular raphides. *Scopolia* has also occurred as a substitute and can be recognised by the characters given under *Scopolia*.

Standard, B.P.—Belladonna root contains not more than 4 per cent. of foreign organic matter and not less than 0.4 per cent. of the alkaloids of belladonna root, calculated as hyoscyamine. Acid-insoluble ash, not more than 4 per cent.

Belladonna root, in powder (*Pulvis Belladonnæ Radicis* : *Pulv. Bellad. Rad.*), contains the constituents and possesses the diagnostic microscopical characters of *Belladonnæ Radix*, and complies with the limits for alkaloids and acid-insoluble ash of the unground drug.

Action and Uses.—The properties of belladonna root are essentially those of belladonna leaf, but the root is used chiefly for preparations for external application. *Collodium Belladonnæ* is especially suitable for painting over joints, or whenever a plaster cannot conveniently be employed. *Emplastrum Belladonnæ* relieves pain and diminishes secretion; it is applied in intercostal neuralgia, lumbago, and to relieve the pain due to adhesions following pleurisy. It is also applied to the cardiac region to relieve pain and palpitation. Belladonna plasters of suitable shape applied to the breast are said to decrease the secretion of milk, but there is reason to believe that non-medicated plasters would have the same effect. Cases of poisoning by absorption have arisen owing to the use of belladonna plaster over too large a surface. *Linimentum Belladonnæ* is used as an anodyne application for lumbago, neuralgia, and rheumatic pains. *Linimentum Belladonnæ cum Chloroformo* is specially suitable for close application to the skin on flannel or piline to relieve neuralgic pain. *Unguentum Belladonnæ* is applied over neuralgic areas to relieve pain; it is also applied to the anus in fissure to relieve pain and muscular spasm. In cases of **poisoning** the procedure described under *Atropina* should be followed.

Dose.—0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains).

Preparations

Chloroformum Belladonnæ, B.P.C.—(*Chlorof. Bellad.*)—Chloroform of Belladonna. Liquid extract of belladonna, 1 in 2.

Collodium Belladonnæ, B.P.C.—(*Collod. Bellad.*)—Belladonna Collodion. *Syn.*—*Emplastrum Belladonnæ Fluidum*; Liquid Belladonna Plaster. Liquid extract of belladonna, 1 in 2, and camphor, about 1 in 60, in a collodion basis.

Emplastrum Belladonnæ, B.P.—(*Emp. Bellad.*)—Plaster of Belladonna. *Syn.*—Belladonna Plaster. Plaster of colophony mixed with a sufficient quantity of a soft alcoholic extract of belladonna root to produce a plaster containing approximately 0.25 per cent. of the alkaloids of belladonna root. A spread belladonna plaster containing the same proportion of alkaloid may be made with a rubber basis.

Extractum Belladonnæ Liquidum, B.P.—(*Ext. Bellad. Liq.*)—Liquid Extract of Belladonna. It is prepared with a mixture of 7 volumes of alcohol (90 per cent.) and 1 volume of distilled water and adjusted to contain 0.75 per cent. w/v of the alkaloids of belladonna root, calculated as hyoscyamine (limits, 0.70 to 0.80); 0.06 millilitre contains 0.00045 gramme and 1 minim contains about $\frac{1}{175}$ grain of alkaloids. **Dose.**—0.015 to 0.06 millilitre ($\frac{1}{4}$ to 1 minim).

Linimentum Aconiti Oleosum, B.P.C.—(Lin. Aconit. Oleos.)—Liniment of Aconite with Oil. *Syn.*—A.B.C. Liniment. Equal parts of liniments of aconite, belladonna and chloroform. (The non-oily liniment of the British Pharmaceutical Codex, 1923 is included under the name of *Pigmentum Aconiti Compositum*.)

Linimentum Belladonnæ, B.P.—(Lin. Bellad.)—Liniment of Belladonna. An alcoholic extract of belladonna root prepared with a mixture of 7 volumes of alcohol (90 per cent.), or industrial methylated spirit suitably diluted, and one volume of distilled water, the product being adjusted to contain 0.375 per cent. w/v of the alkaloids of belladonna root (limits, 0.350 to 0.400), with 5 per cent. w/v of camphor.

Linimentum Belladonnæ cum Chloroformo, B.P.C.—(Lin. Bellad. c. Chlorof.)—Liniment of Belladonna with Chloroform. Chloroform, 1 in 8, with liniment of belladonna

Pigmentum Aconiti Compositum, B.P.C.—(Fig. Aconit. Co.)—Compound Aconite Paint. Liniment of aconite and liniment of belladonna, of each 37.5 per cent. v/v, with chloroform and distilled water.

Suppositorium Belladonnæ, B.P.—(Supp. Bellad.)—Belladonna Suppository. Each suppository contains 0.15 millilitre ($2\frac{1}{2}$ minims) of liquid extract of belladonna, equivalent to about 0.001 gramme ($\frac{1}{100}$ grain) of the alkaloids of belladonna root.

Unguentum Belladonnæ, B.P.C.—(Ung. Bellad.)—Belladonna Ointment. Liquid extract of belladonna, 80 per cent. v/w, evaporated and mixed with wool fat and benzoinated lard; it contains about 0.6 per cent. of the alkaloids of belladonna root.

This ointment was included in the British Pharmacopœia, 1914.

Unguentum Belladonnæ I.A. contains 10 per cent. of **Extractum Belladonnæ I.A.**

BENZALDEHYDUM

(Benzaldehyd.)

Benzaldehyde

$C_7H_6O = 106.0$

Benzaldehyde, $C_6H_5 \cdot CHO$, may be obtained by the catalytic oxidation of toluene by manganese dioxide in the presence of sulphuric acid, or by the hydrolysis of benzal chloride with calcium hydroxide. It occurs as a colourless or slightly yellow, aromatic liquid, with an odour of bitter almond. It solidifies at about 26° and boils at about 180° . The liquid is strongly refractive. On exposure to the air it is oxidised to benzoic acid. It gives the usual reactions for aldehydes, but does not reduce Fehling's solution. Benzaldehyde should be **stored** in small, stoppered bottles, protected from light and air.

Soluble in water (1 in about 350); readily miscible with alcohol, ether, and fixed or volatile oils.

Standard.—Benzaldehyde contains not less than 90 per cent. of C_7H_6O . Specific gravity, 1.049 to 1.053. Refractive index at 20° , 1.554 to 1.556. A mixture of 0.5 millilitre of benzaldehyde, 5 millilitres of water, 0.5 millilitre of sodium hydroxide solution and 0.1 millilitre of ferrous sulphate solution does not produce, on the addition

of excess of hydrochloric acid, a greenish-blue colouration or blue precipitate within fifteen minutes (absence of hydrocyanic acid). Mix 1 millilitre of benzaldehyde with 20 millilitres of alcohol and dilute with water until separation commences; add 5 grammes of zinc and 10 millilitres of dilute sulphuric acid and allow the action to proceed for one hour; filter, evaporate the filtrate to about 20 millilitres and boil with 1 millilitre of N/10 potassium dichromate; no violet colour is produced (absence of nitrobenzene). Take 40 millilitres of concentrated sulphuric acid in a stoppered retort, the beak of which dips beneath the surface of 10 millilitres of N/10 silver nitrate; to the sulphuric acid add 1 gramme of benzaldehyde, mix and add 10 millilitres of nitric acid; warm cautiously until frothing ceases and nitrous fumes are no longer evolved, increase the heat and continue the distillation for thirty minutes; add 1 millilitre of nitric acid to the distillate and boil until colourless; the precipitate, if any, weighs not more than 0.0004 gramme (limit of chlorinated compounds). 5 grammes of benzaldehyde dissolved in neutral alcohol (90 per cent.) requires not more than 4.1 millilitres of N/2 alcoholic potassium hydroxide for neutralisation to phenolphthalein (limit of benzoic acid).

Assay.—Weigh accurately into a stoppered tube about 0.5 gramme of benzaldehyde. Add 20 millilitres of N/2 hydroxylamine hydrochloride and titrate with N/2 alcoholic potassium hydroxide using methyl orange as indicator. From the volume required deduct the volume of alkali required for the free benzoic acid present; each millilitre of N/2 alcoholic potassium hydroxide is equivalent to 0.05326 gramme of C_7H_6O , which allows for the correcting factor for methyl orange.

Uses.—Benzaldehyde is used as a flavouring agent, and is sometimes sold as artificial or synthetic oil of bitter almond.

ALCOHOL PHENYLÆTHYLICUM.—Phenylethyl alcohol, $C_6H_5 \cdot CH_2 \cdot CH_2OH$, is present in oil of rose and other essential oils and may be obtained synthetically from phenylacetic esters. It occurs as a colourless liquid with a rose-like odour and is used in perfumery.

PHENYLACETALDEHYDUM.—Phenylacetaldehyde, $C_6H_5 \cdot CH_2 \cdot CHO$, may be prepared synthetically from cinnamic acid and occurs as a colourless, viscous oil with a powerful, hyacinth-like odour, a specific gravity of about 1.050 to 1.085 and a boiling-point of about 207° . It is used in perfumery.

BENZAMINÆ HYDROCHLORIDUM

(Benzamin. Hydrochlor.)

Benzamine Hydrochloride

Synonym—Betacaine Hydrochloride.

Benzamine hydrochloride is the hydrochloride of the synthetic base, 4-benzoyloxy-2 : 2 : 6-trimethylpiperidine. It occurs as a white,

crystalline powder which is odourless and possesses a slightly bitter taste followed by a sensation of numbness. 0.1 gramme dissolves in 1 millilitre of cold sulphuric acid forming a colourless solution, which, when kept at 100° for five minutes and then cautiously diluted with 2 millilitres of water, develops an aromatic odour, and on cooling deposits crystals of benzoic acid. It gives the reactions of chlorides. A mixture of 0.05 gramme of benzamine hydrochloride with 0.25 gramme of mercurous chloride does not blacken when moistened with water or alcohol (distinction from cocaine hydrochloride). No permanent precipitate is produced by the addition of 5 millilitres of mercuric chloride solution, or 5 millilitres of potassium iodide solution, to separate 5 millilitre portions of a 1 per cent. w/v solution of benzamine hydrochloride (distinction from cocaine and alphacaine respectively).

Soluble in water (1 in 30), alcohol (1 in 35) and chloroform (1 in 6 at 25°).

Standard.—Benzamine hydrochloride melts at approximately 268°, with decomposition. Loss on drying at 100°, not more than 1 per cent. Ash, not more than 0.1 per cent. The aqueous solution (1 in 50) is bright, colourless, and neutral to litmus paper.

Action and Uses.—Benzamine hydrochloride was one of the first important synthetic substitutes for cocaine. It is a local anæsthetic possessing an action and toxicity less than those of cocaine. In excretion this drug differs from cocaine in that it is rapidly destroyed by the liver, none being excreted in the urine. In producing anæsthesia care must be exercised that the solution does not enter a vein. Unlike cocaine it does not dilate the pupil; it is, however, much inferior to this alkaloid when applied to the conjunctiva. It does not constrict blood vessels, but on the contrary produces hyperæmia.

The chief objection to the use of benzamine hydrochloride is that it is intensely irritating and has a devitalising action on the tissues. Solutions containing 0.1 to 2 per cent. w/v in physiological sodium chloride solution are used subcutaneously. Solutions for **injection** may be sterilised by tyndallisation, by filtration, or by boiling for thirty minutes. The quantity of solution used varies according to the purpose for which it is required. A total of 3 to 5 grains has been given with safety. It is **incompatible** with salicylic acid. To prevent poisoning by benzamine, soluble barbitone, 7½ grains, given by the mouth an hour before the operation, is a valuable measure. In cases of **poisoning** by benzamine, strong coffee, alcohol and strychnine should be given, together with oxygen and artificial respiration if the occasion demands.

Dose.—0.008 to 0.03 gramme ($\frac{1}{8}$ to $\frac{1}{2}$ grain).

Preparation

Solvellæ Boracis et Benzaminæ Compositæ, B.P.C.—(Solv. Borac. et Benzamin. Co.)—Compound Solution-Tablets of Borax and Benzamine. *Syn.*—Naso-Pharyngeal Solution-Tablets. Each tablet contains 5 grains of sodium chloride, 3 grains of borax, 1 grain of boric acid, $\frac{1}{2}$ grain of sodium benzoate and $\frac{1}{4}$ grain of benzamine hydrochloride, with menthol, thymol and oil of sweet birch.

BENZAMINÆ LACTAS

(Benzamin. Lact.)

Benzamine Lactate*Synonym*—Betacaine Lactate.

Benzamine lactate is the lactate of the synthetic base, 4-benzoyloxy-2:2:6-trimethylpiperidine. It occurs as a white, crystalline powder, which is odourless and possesses a slightly bitter taste followed by a sensation of numbness. It gives the reaction for benzamine described under benzamine hydrochloride. The tests for distinction from cocaine and alphacaine given under benzamine hydrochloride are also applicable to the lactate.

Soluble in water (1 in 5) and alcohol (1 in 8).

Standard.—Benzamine lactate melts between 152° and 156°. Loss on drying at 100°, not more than 1 per cent. Ash, not more than 0.1 per cent. Solutions of the salt in water are neutral or only faintly alkaline to litmus paper and, in the presence of nitric acid, give no reaction for chlorides or sulphates.

Action and Uses.—Benzamine lactate has an action and toxicity similar to those of benzamine hydrochloride. On account of its ready solubility and the permanence of its solution it is preferable to the hydrochloride when a strong solution is required. Infiltration of localised tender areas is a valuable measure in lumbago and neuralgia. It is not much used in ophthalmic surgery. Solutions of the following strengths may be employed: in dental surgery, 2 per cent. w/v; for infiltration anæsthesia, 0.1 per cent. w/v in normal saline; for regional anæsthesia, 1 to 2 per cent. w/v; for the urethra, 2 per cent. w/v; for the nose, throat and ear, 10 per cent. w/v, as a spray. It is **incompatible** with salicylic acid. Solutions for **injection** may be sterilised by tyndallisation, by filtration, or by boiling for thirty minutes. In cases of **poisoning** the procedure described under Benzaminæ Hydrochloridum should be adopted.

Dose.—0.008 to 0.03 gramme ($\frac{1}{8}$ to $\frac{1}{2}$ grain).

BENZENUM

(Benzene.)

Benzene*Synonym*—Crystallisable Benzene.

Benzene is a hydrocarbon obtained by the fractional distillation of the light oil of coal tar. It is a colourless, mobile liquid, free from

opalescence and having a characteristic odour. The liquid is very inflammable and burns with a luminous, smoky flame. Its flash-point is about 8° . Commercial benzene usually contains small quantities of thiophene and gives a brown colouration when shaken with sulphuric acid, and a blue or green colour is produced on adding a crystal of isatin and further shaking. The thiophene may be removed by shaking the benzene with several small successive quantities of sulphuric acid, washing and rectifying the product; it is then known as "thiophene free." Benzene must be distinguished from benzol, a mixture of aromatic hydrocarbons, and from benzine, one of the many commercial forms of petroleum spirit. A mixture of 9 volumes of carbon tetrachloride and 1 volume of benzene is often referred to as "non-inflammable benzene."

Insoluble in water; miscible with alcohol, ether, acetone, glacial acetic acid and fixed or volatile oils.

Standard.—Benzene solidifies when cooled to 0° , and does not entirely re-melt below 4° . Not less than 95 per cent. w/w distils between 79° and 82° . Specific gravity, 0.880 to 0.887. Residue, when volatilised at 100° , not more than 0.01 per cent. w/v.

Action and Uses.—Benzene possesses the property of reducing the number of leucocytes in the blood, probably by its toxic action on the bone marrow and lymphoid tissue, and has been used in the treatment of the leukæmias. As the action is prolonged, treatment should be carefully controlled by frequent white cell counts and the drug withdrawn before the leucocyte count falls to normal. Owing to its volatile nature the most rapid absorption of benzene occurs when the vapour is inhaled, but for therapeutic purposes the liquid is usually used. It may be **administered** in capsules or as an emulsion by the mouth, or hypodermically as a solution in oil. By either route absorption is very slow, and when taken by the mouth a high proportion escapes by the bowel. The absorbed benzene is excreted in part unchanged by the lungs, and the remainder is slowly oxidised to phenols and other hydroxyl derivatives which appear in the urine in combination as sulphonates and glucuronates. Benzene is a parasiticide and is used as an application for the destruction of pediculi in the head and pubic region, either undiluted or mixed with ten times its volume of soap solution. It is useful in the treatment of seborrhœa, being applied to the skin or brushed into the scalp. It can be employed to prevent bacterial decomposition of organic solutions, but toluene is more suitable for this purpose. The effects of acute **poisoning** by benzene are chiefly confined to the central nervous system; small quantities produce headache, dizziness, and nausea, and larger amounts convulsions and unconsciousness. Treatment consists in washing out the stomach if benzene has been swallowed, and the administration of stimulants and oxygen; if necessary, artificial respiration should be employed. Chronic poisoning is characterised by a marked diminution in the leucocytes, particularly of the polymorphonuclear cells, by

degenerative changes in the liver and kidneys, and by a progressive anæmia.

Dose.—0.3 to 0.6 millilitre (5 to 10 minims).

BENZOL.—Benzol is a mixture of aromatic hydrocarbons obtained from light coal tar oil, and contains about 70 per cent. of benzene, C_6H_6 , together with 20 to 30 per cent. of toluene, $C_6H_5CH_3$. It is a clear, colourless, mobile liquid, with a strong characteristic odour; specific gravity, 0.880 to 0.888. There are various grades of benzol in commerce, designated according to the amount of distillate obtainable under 100° , the percentage referring to this fact, and not to the amount of any particular constituent. Thus, liquids described as 90 per cent. benzol, 50 per cent. benzol and 30 per cent. benzol, are mixtures of benzene with hydrocarbons of higher boiling-point, and the percentage indicates the proportion that will distil below 100° . Benzol is used chiefly as a solvent, and for cleaning purposes.

CYCLOHEXANUM.—Cyclohexane, hexamethylene, or hexahydrobenzene, C_6H_{12} , may be obtained by the catalytic hydrogenation of benzene and occurs as a colourless, mobile liquid having a less pungent odour than that of benzene. It has a specific gravity of about 0.778 to 0.790 and a boiling-point of 81° . It is less toxic than benzene and is sometimes used instead of it.

BENZOCAINA

(Benzocain.)

Benzocaine

Synonym—Ethyl Aminobenzoate.

Benzocaine is ethyl *p*-aminobenzoate, $NH_2 \cdot C_6H_4 \cdot COOC_2H_5$, and may be prepared from *p*-nitrotoluene by oxidation to *p*-nitrobenzoic acid, reduction to *p*-aminobenzoic acid and subsequent esterification with ethyl alcohol. It occurs as a white, odourless, crystalline powder with a slightly bitter taste followed by a sensation of numbness. The aqueous or alcoholic solution is neutral to litmus and it may be extracted from solutions in dilute acids by shaking with ether. When one or two drops of sodium nitrite solution, followed by one or two drops of a solution of betanaphthol in sodium hydroxide solution, are added to 1 millilitre of a 1 per cent. solution in water containing a trace of hydrochloric acid, a deep red colour is produced followed, on standing, by a scarlet precipitate.

Benzocaine may be distinguished from orthocaine by the formation of a precipitate on the addition of iodine solution to a 1 in 50 solution of benzocaine in water acidified with dilute hydrochloric acid; it may be distinguished from amylocaine hydrochloride and from procaine hydrochloride by the fact that these give a precipitate on the addition of potassio-mercuric iodide solution while benzocaine yields no precipitate. It should be **stored** in well-closed containers, protected from light.

Slightly **soluble** in water (about 1 in 2500), alcohol (90 per cent.) (1 in 8), ether (1 in 4), chloroform (1 in 2), almond oil (1 in 50) and olive oil (1 in 35).

Standard, B.P.—Benzocaine has a melting-point of 90° to 91°. Ash, not more than 0.1 per cent. It complies also with limit tests for readily carbonisable substances and free acid.

Action and Uses.—Benzocaine is a local anæsthetic employed mainly for dusting on mucous or ulcerated surfaces. It may be given by the mouth to relieve the pain of gastric carcinoma and is of value as an insufflation, or as a 2 per cent. w/v solution in equal parts of alcohol and water, in tuberculous laryngitis. In combination with atropine and soft paraffin, it is used as an application to sensitive areas in the nose in cases of asthma, or in conjunction with adrenaline in hay fever. Bougies, suppositories and pessaries may be prepared containing 5 grains in each. Externally, benzocaine may be applied to burns and cancerous ulcerations, and is of value in intractable pruritus. It is used as a dusting powder in combination with starch or purified talc, 10 to 50 per cent., or as an ointment with hydrous wool fat, 5 to 10 per cent. It is best **administered** internally in cachets. Solutions of benzocaine in oil for **injection** may be prepared by dissolving the benzocaine in olive oil or almond oil which has been sterilised by heating at 150° for one hour and allowed to cool. The final container is sterilised by heating at 100° for thirty minutes.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

BENZOINUM

(Benzoin.)

Benzoin

Synonym—Gum Benzoin.

Benzoin is a balsamic resin obtained from *Styrax Benzoin* Dryand. (Fam. Styracæ), and is known in commerce as Sumatra benzoin. Normally the tree does not produce benzoin; the formation of oleoresin ducts is induced by hacking the trunk sufficiently deeply to injure the cambium, and after a time the liquid benzoin either accumulates beneath the bark or exudes from the incisions. The exudation is allowed to harden and is exported in blocks.

Benzoin occurs in hard, brittle masses consisting of whitish or reddish tears compacted together by a resinous matrix and varying in colour from greyish-brown to reddish-brown. It has an agreeable, balsamic odour and a slightly acrid taste. When benzoin is heated in a dry tube, irritating whitish fumes are evolved, and a sublimate consisting chiefly of cinnamic acid collects in the cooler portions of the tube. On warming benzoin with potassium permanganate solution an odour of benzaldehyde is produced.

Benzoin **contains** various esters of benzoic and cinnamic acids, together with the free acids. The chief alcohols present in combination are benzoiresinol and coniferyl alcohol and its oxidation products. The

proportion of total cinnamic acid averages approximately double that of the total benzoic acid.

Substitutes.—Other varieties of benzoin occur in commerce, the chief of which is Siam benzoin. This is collected in the Siamese province of Luang Prabang, but the tree which yields it has not been definitely identified; it has been referred to *Styrax Tonkinense* Craib. It is sent to the market either as tears or masses. The tears are flattened or curved and attain as much as 5 centimetres in length and 12 millimetres in thickness; externally they are reddish-yellow, but internally milky-white. Lump or block Siam benzoin consists of tears cemented together with a comparatively large proportion of transparent, reddish-brown resin. Both kinds contain benzoic acid but no cinnamic acid, and have an odour recalling that of vanilla. Penang or "glassy Penang" benzoin comes from Sumatra; it has a greyish, vitreous appearance and no aromatic odour. Palembang benzoin also comes from Sumatra; it consists of a reddish, resinous mass in which are embedded a few scattered tears and has but a slight odour.

Standard, B.P.—Benzoin contains not less than 19 per cent. and not more than 29 per cent. of free balsamic acids, and not less than 30 per cent. and not more than 60 per cent. of total balsamic acids, both calculated on the dry, alcohol-soluble matter. Residue, after continuous extraction with alcohol (90 per cent.) and drying at 100°, not more than 20 per cent. Loss on drying in a vacuum over sulphuric acid, not more than 10 per cent. Acid value, 115 to 163; ester value, 47 to 83; saponification value, 169 to 223, all calculated with reference to the dry, alcohol-soluble matter. Ash, not more than 2 per cent.

Action and Uses.—Benzoin is carminative and antiseptic. It is rapidly absorbed and, during excretion, is mildly expectorant, diuretic, and antiseptic to the urinary passages. It is usually **administered** as Tinctura Benzoini Composita, which is used as an antiseptic and styptic dressing for small cuts by applying it undiluted, and is given internally in chronic bronchitis. When mixed with water, the resinous constituents of compound tincture of benzoin are best suspended with a mixture of equal parts of mucilage of acacia and mucilage of tragacanth, the amount of mucilage used being one-eighth of the volume of the mixture. Benzoin is used externally, in the form of Tinctura Benzoini diluted with water, as a mild stimulant and antiseptic in irritable conditions of the skin. It is a preservative of fats otherwise liable to become rancid, and is therefore used in the preparation of benzoinated lard. Nebula Benzoini Composita is used in a nebuliser as a spray to the nose and throat in catarrhal affections of the respiratory passages.

Dose.—0.6 to 2 grammes (10 to 30 grains).

Preparations

Collodium Stypticum, B.P.C.—(Collod. Stypt.)—Styptic Collodion. Tannic acid, about 1 in 6½, with benzoin, alcohol and simple collodion.

Lotio Benzoini, B.P.C.—(Lot. Benzoin.)—Lotion of Benzoin. *Syn.*—Lait Virginal. Tincture of benzoin, 1 in 40, with rose water.

Nebula Benzoini Composita, B.P.C.—(Neb. Benzoin. Co.)—Compound Benzoin Spray. Oil of pumilio pine, about 1 in 66, and menthol, 1 in 100, with oils of eucalyptus and cassia, in glycerin and tincture of benzoin.

Tinctura Benzoini, B.P.C.—(Tinct. Benzoin.)—Tincture of Benzoin. *Syn.*—Simple Tincture of Benzoin. 1 in 10. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tinctura Benzoini Composita, B.P.—(Tinct. Benzoin. Co.)—Compound Tincture of Benzoin. *Syn.*—Friars' Balsam. Benzoin, 10 per cent. w/v, storax, balsam of tolu and aloes, macerated in alcohol (90 per cent.). Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Unguentum Zinci cum Benzoino, B.P.C.—(Ung. Zinc. c. Benzoin.)—Ointment of Zinc Oxide with Benzoin. Compound tincture of benzoin, about 12·5 per cent. v/w, in ointment of zinc oxide.

BENZYLIS BENZOAS

(Benzyl. Benz.)

Benzyl Benzoate

Benzyl benzoate, $C_6H_5\cdot COOCH_2\cdot C_6H_5$, may be prepared by the action of benzoic acid on benzyl alcohol in the presence of a small quantity of sulphuric acid. It occurs as a white, crystalline solid having a faint, aromatic odour and a sharp, burning taste. It is neutral to litmus. The solution obtained by saponifying benzyl benzoate with alcoholic solution of potassium hydroxide, evaporating, dissolving in water and then neutralising, produces a buff-coloured precipitate with ferric chloride solution; with excess of hydrochloric acid a white, crystalline precipitate of benzoic acid is produced. It melts at 20° to a colourless, oily, neutral liquid which is very liable to become supercooled and may remain liquid for some time at ordinary temperatures. It boils at about 323° .

Insoluble in water and glycerin; miscible in all proportions with alcohol, chloroform and ether.

Standard.—Benzyl benzoate, determined by the method of the British Pharmacopœia for esters in essential oils, but continuing the boiling for two hours over a flame, contains not less than 99 per cent. of $C_{14}H_{12}O_2$; each millilitre of N/2 alcoholic potassium hydroxide is equivalent to 0·1061 gramme of $C_{14}H_{12}O_2$. Specific gravity, 1·121 to 1·125. Refractive index at 20° , 1·568 to 1·570. Ash, not more than 0·05 per cent.

Action and Uses.—Benzyl benzoate, in common with other compounds containing the benzyl group, diminishes the contractions and lowers the tonus of unstriated muscle. It relieves spasm of the bronchioles and plain muscle of the intestine, bladder and uterus, and has been used in intestinal and other forms of colic and especially in asthma. It has been used also in whooping cough and hiccough. It is **administered** as a 20 per cent. solution in alcohol, as an emulsion prepared with one-tenth of its weight of powdered tragacanth, or in gelatin capsules.

Dose.—0·3 to 0·5 millilitre (5 to 8 minims).

ALCOHOL BENZYLICUM.—Benzyl alcohol, $C_6H_5 \cdot CH_2OH$, may be prepared by the alkaline hydrolysis of benzyl chloride and occurs as a colourless, almost odourless liquid with a specific gravity of about 1.049 to 1.055 and a boiling-range of about 200° to 210° . It is miscible with oils and aromatic hydrocarbons but not with water or paraffins, and is used as a plasticiser and solvent in the manufacture of lacquers and varnishes, and in perfumery.

BENZYLIS SUCCINAS

(Benzyl. Succin.)

Benzyl Succinate

Benzyl succinate, $(CH_2 \cdot COOCH_2 \cdot C_6H_5)_2$, may be prepared by heating succinic acid with benzyl alcohol in the presence of a small quantity of sulphuric acid. It occurs as colourless, odourless and almost tasteless crystals.

Soluble in alcohol, ether, chloroform, and fixed and volatile oils; almost insoluble in water.

Standard.—Benzyl succinate, determined by the method of the British Pharmacopœia for esters in essential oils, but continuing the boiling for two hours over a flame, contains not less than 99 per cent. of $C_{18}H_{18}O_4$; each millilitre of N/2 alcoholic potassium hydroxide is equivalent to 0.07454 gramme of $C_{18}H_{18}O_4$. Melting-point, 45° to 47° . Ash, not more than 0.1 per cent.

Action and Uses.—The action of benzyl succinate upon plain muscle is similar to that of benzyl benzoate, and it is used for the same purposes. It contains a larger proportion of the benzyl radicle, and is stated to be less irritating and less nauseating. It is usually **administered** in tablets and sometimes in capsules with papaverine and hyoscyamine.

Dose.—0.3 to 1 gramme (5 to 15 grains).

BERBERIDIS CORTEX

(Berber. Cort.)

Barberry Bark

Barberry bark is the dried bark of the stem of *Berberis vulgaris* Linn. (Fam. Berberidaceæ), a shrub indigenous to Great Britain and distributed over the greater part of Europe and Western Asia.

The bark occurs in thin, slightly curved pieces about 5 centimetres long and 12 millimetres broad; the outer surface is longitudinally wrinkled, the ridges flattened, smooth, greyish in colour and dotted with the minute, black perithecia of ascolichens, the furrows shallow and dark in colour; the inner surface is yellowish-brown, fibrous and

longitudinally striated, and may have fragments of the yellowish wood adhering to it. The bark readily separates into an outer and an inner layer, the fracture of the outer portion being short, and that of the inner part fibrous, the latter also being laminated and traversed by pale yellow medullary rays. The taste is bitter, and the odour slight; it colours the saliva yellow. Examined **microscopically**, a transverse section shows the outer part (rhytidoma) of several series of regular, rectangular cork cells formed from successive phellogens, a narrow, parenchymatous cortex, and the inner part (secondary phloem) of single tangential rows of bast fibres, alternating with layers of soft bast, traversed radially by medullary rays 2 to 4 cells broad.

Barberry bark **contains** berberine, a yellow, crystalline alkaloid, together with oxyacanthine and berbamine, two colourless, crystalline alkaloids.

Action and Uses.—Barberry bark is a bitter tonic. It may be administered in the form of decoction (1 in 20), infusion (1 in 20), or tincture (Tinctura Berberidis Corticis, 1 in 10; dose, $\frac{1}{2}$ to 1 fluid drachm), but generally a salt of the alkaloid berberine is preferred.

BERBERINÆ SULPHAS

(Berberin. Sulph.)

Berberine Sulphate

Synonyms—Berberine Acid Sulphate; Berberinium Acid Sulphate.

Berberine sulphate is the acid salt of a base present in *Berberis vulgaris* Linn. and many other plants. It may be prepared by boiling the powdered drug with water acidified with acetic acid. The decoction is filtered, evaporated to a syrupy liquid and mixed with three times its volume of 20 per cent. sulphuric acid. The crystals thus obtained are washed with cold water, dissolved in boiling water and, after the addition of alcohol and sulphuric acid, again allowed to crystallise. The salt occurs in bright yellow, acicular crystals, or as a dark yellow powder; it has a bitter taste. A solution of 0·05 gramme of berberine sulphate in 5 millilitres of cold water becomes orange-red in colour, but remains clear, on the addition of 2 drops of sodium hydroxide solution; on the addition of 4 drops of acetone a turbidity develops and, on standing, a yellow precipitate (anhydro-berberine-acetone) separates.

Soluble in water (about 1 in 150) and alcohol.

Standard.—Berberine sulphate loses, on drying at 100°, not more than 1 per cent of its weight. Ash, not more than 0·1 per cent. 0·5 gramme in 50 millilitres of water, after precipitation with potassium iodide, leaves an acid solution which requires about 11·5 millilitres of N/10 sodium hydroxide for neutralisation to phenolphthalein,

approximately 11.5 millilitres of N/10 potassium iodide solution being absorbed in the precipitation.

Action and Uses.—Berberine and its salts are employed as bitter stomachics and are used also in the treatment of diarrhoea and of the vomiting of pregnancy. Large doses are said to lower temperature and increase peristalsis. Berberine sulphate has recently been used with success in the treatment of oriental sore (cutaneous leishmaniasis). A solution in sterilised water (0.02 gramme in 1.5 millilitres) is injected subcutaneously at various points around the sore; weekly injections are given, the average period required for healing being seventeen days.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

BERBERINA.—Berberine, $C_{20}H_{19}O_3N$, may be obtained by adding a large excess of sodium hydroxide to an aqueous solution of the sulphate, and extracting with ether. It crystallises from ether in yellow needles which melt at 144° .

BERBERINÆ CARBONAS.—Berberine carbonate, $C_{20}H_{18}O_4N(HCO_3)_2 \cdot 2H_2O$, is a yellowish-brown, acicular, crystalline substance with a bitter taste, insoluble in cold water and soluble in hot water and alcohol.

BERBERINÆ HYDROCHLORIDUM.—Berberine hydrochloride, $C_{20}H_{18}O_4NCl \cdot 2H_2O$, the neutral salt of the base, occurs in bright yellow, acicular crystals or powder with a bitter taste. It is soluble in water (about 1 in 400) and in alcohol, to which it imparts a deep yellow colour.

BERBERINÆ PHOSPHAS.—Berberine acid phosphate, $C_{20}H_{18}O_4N(H_2PO_4), H_3PO_4, 1\frac{1}{2}H_2O$, the acid salt of the base, occurs in bright yellow crystals, having a bitter taste. It is the most soluble salt of berberine, being soluble in water (1 in 15) and precipitated by excess of alcohol. Berberine phosphate is administered in mixtures with chloroform water, or in cachets, or pills.

BERBERIS

(Berber.)

Berberis

Berberis is the dried stem of *Berberis aristata* DC. (Fam. Berberidaceæ), a shrub indigenous to India and Ceylon.

The dried stem occurs in fairly straight pieces, from 1 to 4.5 centimetres in diameter, covered with a greyish-brown cork, which is frequently overgrown with moss and lichens. The surface of the smaller stems exhibits longitudinal wrinkles and the remains of spines, while the older pieces are furrowed irregularly and bear scars of lateral branches. Internally the stem is greenish-yellow, when freshly cut, changing to a cinnamon-brown on exposure to the air. The larger stems split radially on drying. The transversely cut surface shows a narrow ring of dark greenish-yellow phloem, traversed by numerous narrow medullary rays, a radiate wood of very narrow wedges, marked with fairly distinct annual rings, and a small lignified pith from 2.5 to 5 millimetres in diameter.

The diagnostic **microscopical** characters shown in transverse section are a number of layers of lignified cork composed of cells with

moderately thick tangential walls, and amongst them an occasional stone cell; a crescent-shaped mass of pericyclic fibres behind each primary phloem group; the secondary phloem consisting of bands of bast fibres alternating with sieve tubes and bast parenchyma; the portions of the medullary rays passing through the phloem composed of cellulose-walled parenchyma, many of the cells containing one, or rarely two, large prismatic crystals of calcium oxalate; a lignified pith of thin-walled parenchyma.

Berberis **contains** the bitter, yellow alkaloid, berberine.

Substitutes.—The stem of *Berberis Aquifolium* Pursh., a species which is largely cultivated as an ornamental shrub, may be distinguished microscopically by the thick-walled pith cells, the absence of stone cells and calcium oxalate in the medullary rays, the absence of pericyclic fibres behind the phloem bundles and the only occasional occurrence of bast fibres. *B. asiatica* Roxb. has a thin-walled cork with an occasional stone cell, large stone cells being also present among the bast fibres. *B. Chatrii* I. dl. exhibits cork cells with very strongly thickened inner tangential walls, stone cells being absent from this tissue. *B. Lycium* Royle has a thin-walled cork, free from stone cells, the latter being also absent from the rows of phloem fibres. *B. vulgaris* Linn., the only truly British species, may be distinguished by the absence of pericyclic fibres behind the phloem groups, and of stone cells in the medullary rays, and also by the thin-walled pith. The stem of a liane, *Coccoloba fenestratum* Colebr., has often been substituted for berberis, but it may readily be distinguished by the large vessels in the wood which are visible to the naked eye, the absence of annual rings, the crenate ring of sclerenchyma beneath the cortex, and the semi-lunar masses of phloem immediately inside this ring.

Action and Uses.—Berberis is used in India and the Eastern Colonies as a bitter tonic in intermittent fevers. An extract made from various species of berberis, combined with opium, is known as “rusot” in India and is valued as a local application in affections of the eye and eyelids. Berberis is **administered** in the form of a tincture.

Preparation

Tinctura Berberidis, B.P.C.—(Tinct. Berber.)—Tincture of Berberis. 1 in 10. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopæia, 1914.

BETANAPHTHOL

(Betanaph.)

Betanaphthol

Synonym—Naphthol;

Betanaphthol is β -hydroxynaphthalene, $\text{C}_{10}\text{H}_7\text{OH}$, and may be prepared by heating naphthalene with sulphuric acid at 200° ; on fusing the sodium salt of the resulting naphthalene- β -sulphonic acid with sodium hydroxide, the sodium derivative of betanaphthol is formed from which impure betanaphthol is obtained by treatment with hydrochloric acid. It may be purified by recrystallisation or by sublimation. Betanaphthol occurs in white, or nearly white, crystalline lamellæ,

or in powder; it has a slight phenolic odour and a sharp but not persistent taste. When heated in sodium hydroxide solution with a few drops of chloroform, a blue colour is produced. On the addition of dilute ammonia solution to ten times its volume of a cold, saturated, aqueous solution of betanaphthol, a bluish fluorescence is produced. Betanaphthol dissolves in solutions of alkali hydroxides with formation of the alkali derivative.

Slightly **soluble** in water (1 in about 1000); more soluble in boiling water (1 in 75) and in water containing boric acid; readily soluble in alcohol (90 per cent.) (1 in 2), ether (1 in about 1·5), chloroform (1 in 17), olive oil (1 in about 12), glycerin and benzene.

Standard, B.P.—Betanaphthol has a melting-point of 120° to 122°. Ash, not more than 0·05 per cent. It complies also with tests for absence of α -naphthol, naphthalene, and other organic substances, and with a test for neutrality.

Action and Uses.—Betanaphthol is an antiseptic and germicide several times stronger than phenol and much less toxic. In large doses, however, it produces toxic symptoms resembling those of phenol, and it may give rise to irritation and inflammation of the kidneys, resulting in the presence of albumin, casts and hæmoglobin in the urine. It is excreted in combination with glycuronic acid, a small portion being oxidised, and giving to the urine a reddish tint. Betanaphthol is employed as an intestinal antiseptic in putrefactive diarrhœa, in enteric fever, and in the summer diarrhœa of children. It has been used with success as a vermifuge in ankylostomiasis and is also useful in fermentative dyspepsia and other gastric disorders. **Externally**, it is applied in the form of ointment or in solution in oil as a parasiticide in scabies, and as an antiseptic and stimulant in eczema and chronic skin diseases. Soaps containing 2 to 5 per cent. are also used. Betanaphthol is usually **administered** in cachets, capsules, or tablets; it may be usefully combined with charcoal.

Dose.—0·3 to 0·6 gramme (5 to 10 grains).

ALPHANAPHTHOL.—Alphanaphthol, α -hydroxynaphthalene, $C_{10}H_7OH$, occurs in colourless crystals and melts at about 94°. It is a more powerful antiseptic than betanaphthol and is more poisonous. Alphanaphthol is used as a test for carbohy drates. It is used occasionally as an intestinal injection (1 in 4000) and is sometimes prescribed in pills. Dose.—0·12 to 0·3 gramme (2 to 5 grains).

ALUMINII NAPHTHOLSULPHONAS.—Aluminium naphtholsulphonate is a salt of β -naphtholsulphonic acid, containing the equivalent of 5 per cent. of aluminium. It occurs as a whitish powder, very soluble in water, and also soluble in alcohol and glycerin. It is precipitated from its solutions by albumin, but redissolves in excess.

CALCI NAPHTHOLSULPHONAS.—Calcium naphtholsulphonate is obtained by heating 10 parts of β -naphthol with 8 parts of sulphuric acid on a water-bath, until the mass dissolves in water, then diluting with water, neutralising with calcium carbonate, and evaporating the filtrate. It occurs in the form of a white, or reddish-white, odourless, bitter, neutral powder, with a sweetish after-taste. It is soluble in water (1 in 1·5) and alcohol (1 in 3), and precipitates albumin, peptone, etc., from acid solutions. Dose.—0·3 to 1 gramme (5 to 15 grains).

Preparation

Unguentum Betanaphtholis Compositum, B.P.C.—(Ung. Betanaph. Co.)—Compound Betanaphthol Ointment. *Syn.*—Kaposi's Compound Ointment; Unguentum Naphthol Compositum; Compound Naphthol Ointment. Betanaphthol, about 8.5 per cent., with chalk, soft soap and lard.

BETANAPHTHYLIS BENZOAS

(Betanaphthyl. Benz.)

Betanaphthyl Benzoate

Synonyms—Naphthol Benzoate; Benzonaphthol.

Betanaphthyl benzoate, $C_6H_5 \cdot COOC_{10}H_7$, may be prepared by the interaction of betanaphthol and benzoyl chloride. It occurs as a white crystalline, tasteless, odourless powder. The solution in concentrated sulphuric acid is pale yellow in colour, and, when diluted with about ten volumes of water and made alkaline with ammonia, develops a strong green fluorescence.

Almost **insoluble** in water; soluble in alcohol, ether (1 in 40) and chloroform.

Standard.—Betanaphthyl benzoate melts between 107° and 110° . Ash, not more than 0.1 per cent. 1 gramme shaken during one minute with a mixture of 5 millilitres of sodium hydroxide solution and 15 millilitres of water and immediately filtered, produces no blue colour on boiling 10 millilitres of the filtrate with 2 millilitres of chloroform (limit of free betanaphthol); a further 3 millilitre portion of the filtrate, after neutralisation, does not produce a buff-coloured precipitate on the addition of ferric chloride solution (limit of free benzoic acid); the remainder of the filtrate does not produce a blue colouration on the addition of 2 drops of iodine solution (limit of α -naphthol).

Action and Uses.—Betanaphthyl benzoate is used as an intestinal antiseptic. It is decomposed in the intestines into betanaphthol and benzoic acid, the latter substance being absorbed and excreted as hippuric acid. It may be **administered** in mixtures, suspended with mucilage of acacia or tragacanth, but it is best prescribed in **cachets**, which may also contain charcoal and salts of bismuth.

Dose.—0.3 to 1 gramme (5 to 15 grains).

BETANAPHTHYLIS SALICYLAS

(Betanaphthyl. Salicyl.)

Betanaphthyl Salicylate

Synonym—Naphthol Salicylate.

Betanaphthyl salicylate, $C_6H_4(OH)COOC_{10}H_7$, may be prepared

by heating together a mixture of betanaphthol-sodium, sodium salicylate and phosphorus oxychloride. It occurs in colourless, odourless, shining crystals, or as a lustrous, crystalline powder. It is unaffected in the cold by alkalis or acids, but when heated with these reagents in strong solutions it yields betanaphthol and salicylic acid. On adding 0.1 gramme to 2 or 3 millilitres of sulphuric acid, a lemon-yellow solution results in a very short time, which, upon the addition of a trace of nitric acid, changes to olive-green (distinction from salol).

Insoluble in water and glycerin; soluble with difficulty in alcohol, soluble in boiling alcohol (1 in 3), ether (1 in 15), benzene and warm linseed oil.

Standard.—Betanaphthyl salicylate melts between 93° and 95°. Ash, not more than 0.1 per cent. The filtrate, obtained by shaking 1 gramme with 20 millilitres of boiling water and filtering, is neutral to litmus paper (limit of free acid), does not give a crystalline deposit on cooling (limit of free salicylic acid and uncombined betanaphthol), and does not develop a violet colouration, on the addition of 2 drops of ferric chloride solution (limit of fresh salicylic acid).

Action and Uses.—Betanaphthyl salicylate has no action in the stomach, but, owing to its decomposition in the small intestine, exerts there the effects of betanaphthol and of salicylic acid. Its uses resemble those of salol, but its naphthol group is more powerfully antiseptic than the phenol group of salol, and is less liable to give rise to toxic symptoms. It is employed in cases of intestinal fermentation and, less frequently, in rheumatism and rheumatic manifestations. It may be **administered** in mixtures or in cachets.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

BETEL

(Betel)

Betel

Synonym—Betel Leaves.

Betel consists of the dried leaves of *Piper Betle* Linn. (Fam. Piperaceæ), a plant indigenous to and cultivated in India, Ceylon and the Malay Islands. The leaves are picked while green, pressed together by means of stones, dried and tied up into small packets.

The leaves are broadly ovate, up to about 15 centimetres long and 10 centimetres broad, with acuminate apex and cordate base, or they are ovate-oblong and oblique with an unequal base; five to seven prominent lateral veins, arising from the basal fourth of the midrib, turn outwards towards the margin and curve in an arc towards the apex; they are dull brown, thin and brittle; the mesophyll contains numerous small oil cells filled with a dark brown secretion. The taste is slight, warm and aromatic.

Betel contains a volatile oil (0·2 to 1·0 per cent.) containing betel-phenol (chavibetol, an isomeride of eugenol), chavicol, cadinene and various sesquiterpenes.

Action and Uses.—Betel possesses antiseptic, stimulant and carminative properties and is used in India as a masticatory. The juice obtained from the fresh leaves has similar properties. The Malays use the leaves, generally admixed with lime and scrapings of areca nut, for the same purpose.

BISMUTHI CARBONAS

(Bism. Carb.)

Bismuth Carbonate

Synonyms—Bismuth Oxycarbonate; Bismuth Subcarbonate.

Bismuth carbonate may be prepared by the interaction of solutions of bismuth nitrate and a soluble carbonate. It is a basic salt, the composition of which varies with the conditions under which it is precipitated, but is represented approximately by the formula $(\text{Bi}_2\text{O}_2\text{CO}_3)_2, \text{H}_2\text{O}$. It occurs as a white or creamy-white powder without odour or taste, and is stable in air. The bulk-density of bismuth carbonate varies considerably and depends largely upon the conditions of precipitation. It is completely soluble with effervescence in mineral acids, forming solutions of bismuth salts.

Insoluble in water and neutral organic solvents.

Standard, B.P.—Bismuth carbonate leaves on ignition not less than 89 per cent. and not more than 91 per cent. of residue. Arsenic limit, 2 parts per million. It complies also with a test for absence of silver and with limit tests for lead, copper, sulphate, alkalis and alkaline earths, nitrate and chloride.

Action and Uses.—Bismuth carbonate is prescribed, like other salts of bismuth, for its local action. Administered **internally** it is not absorbed, but forms a coating on the walls of the stomach and intestines, protecting them from irritation caused by food and the secretions, and allaying inflammation. Bismuth carbonate is, therefore, of value in dyspepsia and vomiting, also in gastric inflammation and diarrhœa. In the intensive alkaline treatment of gastric and duodenal ulcer, bismuth carbonate is largely employed in conjunction with magnesium carbonate, sodium bicarbonate, and calcium carbonate or chalk; various mixtures of these substances, such as Pulvis Bismuthi Compositus, are described as MacLean's Powder. **Externally**, bismuth carbonate is sedative and astringent; it is occasionally used in the form of ointment, lotion or dusting powder in irritable conditions of the skin. Symptoms of poisoning may occur due to absorption from large raw surfaces. Salts of bismuth obstruct the passage of X-rays and large quantities (2 to 6 ounces) of the carbonate or subchloride, suspended in a

suitable medium, may be given to assist the X-ray diagnosis of disorders of the stomach and intestines. As barium sulphate serves equally well for this purpose and is much less costly, bismuth is now rarely used. A thin cream of bismuth carbonate with mucilage may be injected into sinuses to show their extent under X-rays.

Bismuth carbonate may be **administered** in cachets, powders or mixtures. Bismuth salts of high density are most suitable for dispensing in cachets. For the preparation of mixtures, those of medium or low density should be selected. If such practice is followed the use of suspending agents in mixtures containing bismuth salts is not essential. Preference should be given to compound powder of tragacanth when substances necessitating the use of a suspending agent are ordered with bismuth salts; the addition of mucilage of acacia or powdered acacia is liable to produce indiffusible masses in the mixture. For administration in lozenge form, *Trochiscus Bismuthi Compositus* is preferred; or soft gelatin pastilles may be used, containing a larger proportion of bismuth, with morphine or cocaine, if desired.

Dose.—0.6 to 2 grammes (10 to 30 grains).

Preparations

Glycerinum Bismuthi Carbonatis, B.P.C.—(Glycer. Bism. Carb.)—Glycerin of Bismuth Carbonate. Bismuth carbonate, 50 per cent. w/v, in distilled water and glycerin. Dose.—0.6 to 4 millilitres (10 to 60 minims).

Mistura Bismuthi et Sodii Bicarbonatis, B.P.C.—(Mist. Bism. et Sod. Bicarb.)—Bismuth and Sodium Bicarbonate Mixture. *Syn.*—*Mistura Bismuthi cum Soda*; Bismuth and Soda Mixture. Each fluid ounce contains 10 grains each of bismuth carbonate, sodium bicarbonate and light magnesium carbonate, in distilled water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Mistura Bismuthi et Pancreatini, B.P.C.—(Mist. Bism. et Pancreatini.)—Mixture of Bismuth and Pancreatin. Each fluid ounce contains 10 grains each of bismuth carbonate and sodium bicarbonate, 4 grains of pancreatin and 4 minims of dilute hydrocyanic acid, in chloroform water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Pasta Bismuthi, B.P.C.—(Past. Bism.)—Bismuth Paste. Bismuth carbonate, 30 per cent., in white soft paraffin.

Pulvis Bismuthi Compositus, B.P.C.—(Pulv. Bism. Co.)—Compound Bismuth Powder. Bismuth carbonate, 1 part; calcium carbonate, 3 parts; heavy magnesium carbonate, 3 parts; sodium bicarbonate, 1 part. Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

Tabellæ Bismuthi et Sodii Bicarbonatis, B.P.C.—(Tab. Bism. et Sod. Bicarb.)—Bismuth and Sodium Bicarbonate Tablets. Each tablet contains 2 grains of bismuth carbonate and 3 grains of sodium bicarbonate. Dose.—1 to 3 tablets.

Trochiscus Bismuthi Compositus, B.P.—(Troch. Bism. Co.)—Compound Lozenge of Bismuth. *Syn.*—Compound Bismuth Lozenge. Each lozenge contains approximately 0.15 gramme or $2\frac{1}{4}$ grains each of bismuth carbonate and heavy magnesium carbonate and approximately 0.3 gramme or $4\frac{1}{2}$ grains of calcium carbonate, in a basis flavoured with oil of rose.

Trochisci Alkalini Compositi, B.P.C.—(Troch. Alk. Co.)—Compound Alkaline Lozenges. Each lozenge contains 12 grains of compound bismuth powder.

Unguentum Bismuthi, B.P.C.—(Ung. Bism.)—Bismuth Ointment. Bismuth carbonate, 12.5 per cent., in white soft paraffin.

BISMUTHI CITRAS

(Bism. Cit.)

Bismuth Citrate

Bismuth citrate is probably a monobismuthylcitric acid, $\text{H}_2\text{C}_6\text{H}_5\text{O}_7$ (BiO), and may be obtained by mixing citric acid with bismuth subnitrate and distilled water, heating on a water-bath with frequent stirring until a drop of the mixture yields a clear solution with solution of ammonia, adding water, allowing to deposit, washing the precipitate thus obtained until the washings are tasteless, and drying at a gentle heat. It occurs as a white, crystalline powder without odour or taste.

Insoluble in water and alcohol; soluble in solution of ammonia.

Standard.—Bismuth citrate yields on ignition, followed by re-ignition with a few drops of nitric acid, not less than 55 per cent. and not more than 59 per cent. of residue, Bi_2O_3 . Arsenic limit, 2 parts per million. It complies with the tests of the British Pharmacopœia for chlorides, sulphates, silver and alkalis and alkaline earths in Bismuthi Salicylas. 5 millilitre portions of the filtrate obtained by igniting 3 grammes, dissolving the residue in 4 millilitres of nitric acid, evaporating to half its volume and diluting to 100 millilitres with water and then filtering, comply with the limit tests for lead and copper in Bismuthi Carbonas. 0.01 gramme treated with 1 millilitre of water and 5 millilitres of sulphuric acid, cooled, and 5 millilitres of ferrous sulphate solution carefully superimposed, shows no red or brown zone within five minutes (limit of nitrate).

Action and Uses.—Bismuth citrate may be used instead of bismuth carbonate and subnitrate for its local action on the stomach and intestines. Gauze impregnated with bismuth citrate has been used in place of iodoform gauze and has the advantage of being odourless.

Dose.—0.12 to 0.3 gramme (2 to 5 grains).

Preparations

Liquor Bismuthi Concentratus, B.P.C.—(Liq. Bism. Conc.)—Concentrated Solution of Bismuth. It contains the equivalent of from 10 to 12 per cent. w/v of Bi_2O_3 and is twice the strength of solution of bismuth and ammonium citrate. Dose.—1 to 2 millilitres ($\frac{1}{4}$ to $\frac{1}{2}$ fluid drachm).

Liquor Bismuthi et Ammonii Citratis, B.P.C.—(Liq. Bism. et Ammon. Cit.)—Solution of Bismuth and Ammonium Citrate. It contains the equivalent of from 5 to 6 per cent. w/v of Bi_2O_3 . Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This solution, prepared from bismuth subnitrate and citric acid, was included in the British Pharmacopœia, 1914.

Mistura Bismuthi Composita, B.P.C.—(Mist. Bism. Co.)—Compound Bismuth Mixture. Each fluid drachm contains $\frac{1}{2}$ fluid drachm of concentrated solution of bismuth, $7\frac{1}{2}$ minims of tincture of nux vomica and 2 minims of dilute hydrocyanic acid, with chloroform, solution of bordeaux B and distilled water. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Mistura Bismuthi Composita cum Pepsino, B.P.C.—(Mist. Bism. Co. c. Pepsin.)—Compound Bismuth Mixture with Pepsin. Each fluid drachm contains $\frac{1}{2}$ fluid drachm of concentrated solution of bismuth, 1 grain of pepsin,

7½ minims of tincture of nux vomica and 2 minims of dilute hydrocyanic acid, with chloroform, solution of bordeaux B and distilled water. Dose.— 2 to 4 millilitres (½ to 1 fluid drachm).

Mistura Bismuthi Composita cum Pepsino et Morphina, B.P.C.—(Mist. Bism. Co. c. Pepsin. et Morph.)—Compound Bismuth Mixture with Pepsin and Morphine. Each fluid drachm contains $\frac{1}{4}$ grain of morphine hydrochloride in compound bismuth mixture with pepsin. Dose.— 2 to 4 millilitres (½ to 1 fluid drachm).

BISMUTHI ET AMMONII CITRAS

(Bism. et Ammon. Cit.)

Bismuth and Ammonium Citrate

Synonym—Bismuth-ammonium Citrate.

Bismuth and ammonium citrate may be prepared by dissolving bismuth citrate in ammonia solution, filtering, evaporating the solution to a syrupy consistence and spreading on glass plates to dry. It occurs as shining, semi-opaque scales, or as a white, odourless powder, with a slightly metallic taste.

Slowly **soluble** in water; slightly soluble in alcohol.

Standard.—Bismuth and ammonium citrate yields on ignition not less than 46 per cent. and not more than 50 per cent. of residue, Bi_2O_3 . Arsenic limit, 2 parts per million. 5 millilitre portions of the filtrate obtained by igniting 4 grammes, dissolving the residue in 4 millilitres of nitric acid, evaporating to half its volume and diluting to 100 millilitres with water and then filtering, comply with the limit tests for lead, copper, silver and alkaline earths in Bismuthi Carbonas. 0.01 gramme treated with 1 millilitre of water and 5 millilitres of sulphuric acid, cooled and 5 millilitres of ferrous sulphate solution carefully superimposed, produces no red or brown zone within five minutes (limit of nitrate).

Action and Uses.—Bismuth and ammonium citrate is best **administered** in aqueous solution or as Liquor Bismuthi et Ammonii Citratis since it is somewhat astringent and irritating. It should not be prescribed when there is acute inflammation.

Dose.— 0.12 to 0.3 gramme (2 to 5 grains).

BISMUTHI ET SODII TARTRAS

(Bism. et Sod. Tart.)

Bismuth Sodium Tartrate

Synonyms—Soluble Bismuth Tartrate; Acid Bismuth Sodium Tartrate.

Bismuth sodium tartrate consists of a mixture of bismuth and sodium tartrates with an excess of tartaric acid, and may contain

sodium salts of bismuthytartaric acids. It may be prepared by dissolving bismuth tartrate in solution of sodium hydroxide, adding an excess of tartaric acid and evaporating the solution. Bismuth tartrate, $\text{H}_2\text{C}_4\text{H}_4\text{O}_6 \cdot 2\text{H}(\text{BiO})\text{C}_4\text{H}_4\text{O}_6$, or $\text{Bi}_2(\text{C}_4\text{H}_4\text{O}_6)_3$, for this purpose, is prepared by interaction between bismuth subnitrate and tartaric acid in the presence of water by a process similar to that described for bismuth citrate. When bismuth tartrate is obtained by other methods it may contain different proportions of bismuth and tartrate and when dissolved in the sodium hydroxide solution, unless properly adjusted, may on evaporation yield a product of more variable composition. It occurs as a white powder or in scales.

Slowly, but completely **soluble** in water forming a strongly acid solution.

Standard.—Bismuth sodium tartrate, determined by the method for bismuth in Bismuthi Subchloridum, using about 0.5 gramme accurately weighed, contains not less than 38 per cent. and not more than 44 per cent. of Bi. Arsenic limit, 2 parts per million. 5 millilitre portions of the filtrate obtained by igniting 4 grammes, dissolving the residue in 4 millilitres of nitric acid, evaporating to half its volume and diluting to 100 millilitres with water and then filtering, comply with the limit tests for lead, copper and silver in Bismuthi Carbonas. 0.01 gramme, treated with 1 millilitre of water and 5 millilitres of sulphuric acid, cooled and 5 millilitres of ferrous sulphate solution carefully superimposed, produces no red or brown zone within five minutes (limit of nitrate).

Action and Uses.—Bismuth sodium tartrate may be used instead of bismuth carbonate for its local action on the walls of the stomach and intestines. It is best **administered** as Liquor Bismuthi Acidus, which is a suitable preparation of bismuth for mixtures containing pepsin.

Dose.—0.12 to 0.3 gramme (2 to 5 grains).

BISMUTHI ET SODII TARTRAS (NEUTRAL).—Neutral bismuth sodium tartrate suitable for purposes of injection may be obtained in solution by dissolving bismuth tartrate in the requisite amount of sodium hydroxide solution or, in the solid condition, by evaporation of the neutral solution. Aqueous solutions of bismuth and sodium tartrate for injection may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. Only suspensions may be prepared with olive oil or almond oil which has been sterilised by heating at 150° for one hour and allowed to cool; the final container is sterilised at 100° for thirty minutes.

Preparations

Liquor Bismuthi Acidus, B.P.C.—(Liq. Bism. Acid.)—Acid Solution of Bismuth. A solution of an acid bismuth sodium tartrate containing the equivalent of from 9 to 10 per cent. w/v of Bi_2O_3 . Dose.—1 to 2 millilitres ($\frac{1}{4}$ to $\frac{1}{2}$ fluid drachm).

Mistura Bismuthi Composita Acidum Pepsino, B.P.C.—(Mist. Bism. Co. Acid. c. Pepsin.)—Compound Acid Mixture of Bismuth with Pepsin. Each fluid drachm contains acid solution of bismuth equivalent to about 5 grains of bismuth sodium tartrate, 1 grain of pepsin, and about $\frac{1}{2}$ minim of liquid extract of nuxvomica, with dilute hydrocyanic acid, solution of bordeaux B and double chloroform water. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

BISMUTHI NAPHTHOLAS

(Bism. Naphthol.)

Bismuth Naphtholate*Synonym*—Bismuth Betanaphtholate.

Bismuth naphtholate may be obtained by the action of sodium naphtholate on bismuth nitrate, or of an alkaline solution of betanaphthol on a solution of bismuth nitrate in glycerin or dilute acid. It occurs as a pinkish-brown, odourless, nearly tasteless and neutral powder, darkening on keeping. It should be free from sharp odour or burning taste (distinction from a mixture of betanaphthol and bismuth salt).

Insoluble in water; slightly soluble in alcohol.

Standard.—Bismuth naphtholate yields on ignition, followed by re-ignition with a few drops of nitric acid, not less than 73 per cent. and not more than 78 per cent. of residue, Bi_2O_3 . When treated with excess of hydrochloric acid and extracted by shaking with successive portions of chloroform, it yields not less than 15 per cent. of betanaphthol. Arsenic limit, 2 parts per million. 5 millilitre portions of the filtrate obtained by igniting 3 grammes, dissolving the residue in 4 millilitres of nitric acid, evaporating to half its volume and diluting to 100 millilitres with water and then filtering, comply with the limit tests for lead, copper, silver, and alkalis and alkaline earths in Bismuthi Carbonas.

Action and Uses.—Bismuth naphtholate is decomposed in the intestine, betanaphthol being liberated. It is employed as an intestinal disinfectant, its action in this respect resembling that of betanaphthol. The naphtholate is often employed in combination with sodium bicarbonate and wood charcoal, and is administered enclosed in a cachet. It may be used **externally** as a dusting powder in the treatment of skin diseases and ulcers in place of iodoform.

Dose.—0.3 to 1 gramme (5 to 15 grains).

BISMUTHI OLEAS

(Bism. Oleas)

Bismuth Oleate

Bismuth oleate may be obtained by the interaction of solutions of bismuth nitrate and hard soap. It occurs in nearly white, pasty masses or as a white powder.

Standard.—Bismuth oleate yields on ignition, followed by re-ignition with a few drops of nitric acid, not less than 20 per cent. and not more than 22 per cent. of residue, Bi_2O_3 .

Action and Uses.—Bismuth oleate is used with zinc oxide or starch as a dusting powder in hyperæmic conditions of the skin, or in the form of Unguentum Bismuthi Oleatis for chapped hands.

Preparation

Unguentum Bismuthi Oleatis, B.P.C.—(Ung. Bism. Oleat.)—Bismuth Oleate Ointment. Bismuth oleate, 12·5 per cent., in white soft paraffin.

BISMUTHI OXIDUM

(Bism. Oxid.)

Bismuth Oxide

Bismuth oxide may be prepared by the interaction of bismuth subnitrate with boiling solution of sodium hydroxide. It occurs as a lemon-yellow powder, which is dissolved by moderately strong hydrochloric or nitric acid.

Insoluble in water.

Standard.—Bismuth oxide loses on ignition not more than 1 per cent. of its weight. Arsenic limit, 2 parts per million.

Action and Uses.—Bismuth oxide resembles the carbonate and subnitrate in its therapeutic action. One part with 7 parts of benzoinated lard forms a useful sedative ointment which is, in some cases, preferable to zinc ointment.

Dose.—0·3 to 1·2 grammes (5 to 20 grains).

Bismuthi Hydroxidum.—Bismuth hydroxide is the name applied to the yellow, partly hydrated bismuth oxide, and to the white, hydrated oxide, which frequently contains a large proportion of carbonate or oxysalt, precipitated from solutions of bismuth salts by the addition of alkali. Bismuth hydroxide has the same action as the carbonate, although it is less frequently used. Suspensions in oil or water have been used as injections in the treatment of syphilis. Suspensions in oil for injection may be prepared by mixing the bismuth hydroxide with olive oil or almond oil which has been sterilised by heating at 150° for one hour and allowed to cool. The final container may be sterilised at 100° for thirty minutes. **Dose.**—0·3 to 1·2 grammes (5 to 20 grains).

Preparations

Mistura Bismuthi et Magnesii Hydroxidum, B.P.C.—(Mist. Bism. et Mag. Hydrox.)—Mixture of Bismuth and Magnesium Hydroxides. Equal parts of mixture of bismuth hydroxide and mixture of magnesium hydroxide. **Dose.**—4 to 8 millilitres (1 to 2 fluid drachms).

Mistura Bismuthi Hydroxidi, B.P.C.—(Mist. Bism. Hydrox.)—Bismuth Hydroxide Mixture. *Syn.*—Magma Bismuthi. It contains the equivalent of from 9 to 11 per cent. w/v of Bi_2O_3 . **Dose.**—4 to 8 millilitres (1 to 2 fluid drachms).

BISMUTHI OXYIOGALLAS

(Bism. Oxyiodogall.)

Bismuth Oxyiodogallate

Synonym—Bismuth Oxyiodosubgallate.

Bismuth oxyiodogallate may be prepared by treating bismuth oxyiodide with gallic acid, or by heating bismuth subgallate with hydriodic

acid, until a greyish-green product is obtained, the resulting powder being subsequently well washed and dried at a moderate temperature. It occurs as a bulky, greyish or greyish-green, odourless and tasteless powder, which darkens on exposure to moist air. It is decomposed by alkalis and mineral acids; with concentrated sulphuric acid iodine is liberated.

Insoluble in water, alcohol, ether and chloroform.

Standard.—Bismuth oxyiodogallate leaves on ignition not less than 43 per cent. and not more than 45 per cent. of residue, Bi_2O_3 ; it contains not less than 20 per cent. of I.

Assay.—Heat about 0.5 gramme, accurately weighed, with 10 millilitres of 2N sodium hydroxide until dissolved; cool and add 20 millilitres of N/10 silver nitrate and 20 millilitres of nitric acid; boil for five minutes, dilute with water to about 100 millilitres, cool, and titrate with N/10 ammonium thiocyanate, using ferric ammonium sulphate as indicator and correcting for the chloride present in the 10 millilitres of 2N sodium hydroxide; each millilitre of N/10 silver nitrate is equivalent to 0.01269 gramme of I.

Action and Uses.—Bismuth oxyiodogallate is used chiefly as an application in skin diseases in which an astringent and protective powder is indicated. It is free from toxic and irritant properties and covers about four times as much surface as an equal weight of iodoform, for which it may be used as a substitute. It may be applied to burns and ulcers, and as a dusting powder after operations; it is also used in the form of ointment (10 per cent.) prepared with soft paraffin or paraffin ointment. Suppositories containing 0.12 to 0.2 gramme (2 to 3 grains) are used in the treatment of hæmorrhoids.

BISMUTHI SALICYLAS

(Bism. Salicyl.)

Bismuth Salicylate

Synonym—Bismuth Subsalicylate.

Bismuth salicylate may be prepared by the interaction of hydrated bismuth oxide and salicylic acid. It is a basic salt, corresponding approximately to the formula, $\text{C}_6\text{H}_4(\text{OH})\cdot\text{COOBiO}$. It occurs as a white or nearly white, amorphous powder, without odour or taste. It is stable in air, but is partially dissociated by contact with water or alcohol with liberation of salicylic acid and formation of a more basic salt. The salicylic acid radicle may be detected in bismuth salicylate by shaking with ether and dilute sulphuric acid; salicylic acid passes into the ethereal layer in which it may be detected

by the violet colouration produced on shaking with water containing a trace of ferric chloride. It should be **stored** protected from light.

Insoluble in water.

Standard, B.P.—Bismuth salicylate yields on ignition, followed by re-ignition at a low red heat with a few drops of nitric acid, not less than 62 per cent. and not more than 66 per cent. of residue, Bi_2O_3 . Arsenic limit, 2 parts per million. It complies also with a test for absence of silver and with limit tests for free salicylic acid, lead, copper, chloride, sulphate, nitrate and for alkalis and alkaline earths.

Action and Uses.—Bismuth salicylate is a valuable intestinal antiseptic and protective to the intestinal tract. It is especially useful for the treatment of summer diarrhoea of children, dysentery, typhoid fever, and of ulcerative colitis. Bismuth salicylate is best **administered** in cachets, or it may be suspended in mixtures with mucilage of tragacanth. It may be rendered more easily miscible with water by the addition of alcoholic preparations. The use of a suspending agent is not necessary when a bismuth salicylate of low density is employed with compound infusion of orange or compound infusion of gentian as a vehicle. Bismuth salicylate is decomposed in the presence of alkali bicarbonates with effervescence. In dispensing mixtures containing the salicylate and a bicarbonate, the two reacting salts should be rubbed together with warm water and the conversion to carbonate accomplished before the mixture is completed. Bismuth salicylate suspended in oil has given satisfactory results in the treatment of syphilis when administered intramuscularly and may be used in the form of *Injectio Bismuthi Salicylatis*. Suspensions of bismuth salicylate in oil for **injection** may be prepared by mixing bismuth salicylate with olive oil or almond oil which has been sterilised by heating at 150° for one hour and allowed to cool. The final container may be sterilised by heating at 100° for thirty minutes.

Dose.—0.6 to 2 grammes (10 to 30 grains), by the mouth; 0.06 to 0.12 gramme (1 to 2 grains), by intramuscular injection.

BISMUTHI BENZOAS.—Bismuth benzoate, $\text{C}_6\text{H}_5\cdot\text{COO}(\text{BiO})_2$, occurs as a white powder, containing the equivalent of about 65 per cent. of bismuth oxide. It is insoluble in water. Bismuth benzoate has medicinal properties similar to those of the salicylate and may be given in similar doses.

Preparation

Injectio Bismuthi Salicylatis, B.P.—(*Inf. Bism. Salicyl.*)—Injection of Bismuth Salicylate. A sterile preparation containing bismuth salicylate, 10 per cent., w/v, with camphor and phenol, in sterilised olive oil; 1.2 millilitres contains 0.12 gramme, and 20 minims contains about 2 grains, of bismuth salicylate. **Dose.**—0.6 to 1.2 millilitres (10 to 20 minims), by intramuscular injection.

BISMUTHI SUBCHLORIDUM

(Bism. Subchlor.)

Bismuth Subchloride*Synonym*—Bismuth Oxychloride.

Bismuth subchloride may be prepared by adding a solution of bismuth nitrate to a solution of sodium chloride, or to very dilute hydrochloric acid; it may also be prepared by pouring a solution of bismuth oxide in hydrochloric acid into water. It occurs as a lustrous, impalpable, white powder. Bismuth subchloride prepared by precipitating bismuth nitrate with sodium chloride is known as "blanc d'Espagne," or flake-white; when similarly prepared by precipitating with dilute hydrochloric acid it is termed "blanc de perle" or pearl-white.

Insoluble in water; readily soluble in acids.

Standard.—Bismuth subchloride contains not less than 79 per cent. and not more than 81 per cent. of Bi, and not less than 12·5 per cent. of Cl. It dissolves completely in nitric acid without effervescence (limit of carbonate and insoluble material).

Assay.—For bismuth. Dissolve about 0·2 gramme, accurately weighed, in 2 millilitres of hydrochloric acid; dilute to 30 millilitres with water and precipitate the bismuth as sulphide by passing hydrogen sulphide through the solution; dissolve the precipitate in hot nitric acid diluted with an equal volume of water, precipitate the bismuth as carbonate, wash, dry, ignite and weigh the residue of Bi_2O_3 ; 1 gramme of Bi_2O_3 is equivalent to 0·8970 gramme of Bi.

For chlorine. Dissolve 0·5 gramme in 10 millilitres of a mixture of equal parts of nitric acid and water and add 20 millilitres of N/10 silver nitrate. Boil for ten minutes, cool, and titrate with N/10 ammonium thiocyanate using ferric ammonium sulphate as indicator; each millilitre of N/10 silver nitrate is equivalent to 0·003546 gramme of Cl.

Action and Uses.—Bismuth subchloride may be used internally or externally in place of other inorganic salts of bismuth. The fineness of the powder and the readiness with which it adheres to the skin render it of value as a cosmetic. It may be applied to mucous surfaces by insufflation. It is also used for hæmorrhoids and dysentery in the form of suppositories (10 grains in each), or as an ointment (6 per cent.). As a suspension in camphor water, bismuth subchloride is employed by intramuscular injection in the treatment of syphilis; doses of 0·2 to 0·3 gramme may be given twice weekly up to a total of 2 to 3 grammes in 10 or 15 injections.

Dose.—0·3 to 1·2 grammes (5 to 20 grains).

Preparation

Unguentum Resorcinolis et Bismuthi Compositum, B.P.C.—(Ung. Resorcin. et Bism. Co.)—Compound Resorcinol and Bismuth Ointment. *Syn.*—Unguentum Resorcini et Bismuthi Compositum; Compound Bismuth and Resorcin Ointment. Resorcinol and bismuth subchloride, of each, 8 per cent., with distilled water, zinc oxide, starch, birch tar oil, oil of cade and wool fat.

BISMUTHI SUBGALLAS

(Bism. Subgall.)

Bismuth Subgallate*Synonym*—Bismuth Oxygallate.

Bismuth subgallate is prepared by the action of gallic acid on freshly precipitated hydrated bismuth oxide. It occurs as a citron-yellow, odourless, and tasteless powder. On heating, it decomposes without melting. When the bismuth is removed by suspending the salt in water and passing hydrogen sulphide, the solution, after filtering and boiling, gives a bluish-black colour with ferric chloride.

Insoluble in water, ether and alcohol; readily soluble in the hot mineral acids, with decomposition, and in solutions of the alkali hydroxides, forming clear, yellow solutions, rapidly turning to deep red.

Standard.—Bismuth subgallate yields on ignition, followed by re-ignition with a few drops of nitric acid, not less than 52 per cent. and not more than 57 per cent. of residue, Bi_2O_3 , calculated on the substance dried at 100° . Loss on drying at 100° , not more than 5 per cent. Arsenic limit, 2 parts per million. 5 millilitre portions of the filtrate, obtained by igniting 3 grammes, dissolving the residue in 4 millilitres of nitric acid, evaporating to half its volume and diluting to 100 millilitres with water, and then filtering, comply with the limit tests for lead, copper, silver, and alkalis and alkaline earths in Bismuthi Carbonas. 0.01 gramme treated with 1 millilitre of water and 5 millilitres of sulphuric acid, cooled, and 5 millilitres of ferrous sulphate solution carefully superimposed, shows no red or brown zone within five minutes (limit of nitrate). When 1 gramme is shaken with 20 millilitres of alcohol (90 per cent.) for one minute, filtered and the filtrate evaporated to dryness on a water-bath, not more than 0.001 gramme of residue is obtained (limit of free gallic acid).

Action and Uses.—Bismuth subgallate has mild astringent properties, and is sometimes given for diarrhœa and colitis. It is usually **administered** in cachets. An 8 per cent. suspension in mucilage of starch may be used as an injection in the treatment of gonorrhœa. It is employed as an ointment (1 in 10) for eczema and burns, and as suppositories for the treatment of hæmorrhoids. Bismuth subgallate is also used as a dusting powder, either alone or diluted with starch, purified talc, zinc oxide, or boric acid.

Dose.—0.6 to 2 grammes (10 to 30 grains).

Preparations

Suppositorium Bismuthi Subgallatis, B.P.C.—(Supp. Bism. Subgall.)—Bismuth Subgallate Suppository. Each suppository contains 5 grains of bismuth subgallate.

Suppositorium Bismuthi Subgallatis Compositum, B.P.C.—(Supp. Bism. Subgall. Co.)—Compound Bismuth Subgallate Suppository. *Syn.*—Suppositorium Bismuthi et Resorcini Compositum; Compound Bismuth and Resorcin Suppository. Each suppository contains 3 grains of bismuth subgallate, 1 grain of resorcinol, 2 grains of zinc oxide and 1 minum of balsam of Peru.

BISMUTHI SUBNITRAS

(Bism. Subnit.)

Bismuth Subnitrate*Synonym*—Bismuth Oxynitrate.

Bismuth subnitrate is a basic salt and may be prepared by pouring a solution of bismuth nitrate into water containing sodium hydroxide. It occurs as a white, microcrystalline, odourless and tasteless powder which is slightly acid to litmus. The product has the composition $6\text{Bi}_2\text{O}_3, 5\text{N}_2\text{O}_5, 9\text{H}_2\text{O}$, which yields about 80 per cent. of Bi_2O_3 , whereas the definite oxysalt of the formula $\text{BiONO}_3, \text{H}_2\text{O}$, obtained by precipitation from water without alkali, yields about 76 per cent. of Bi_2O_3 .

Insoluble in water and alcohol; readily soluble in nitric or hydrochloric acid.

Standard.—Bismuth subnitrate yields on ignition not less than 79 per cent. and not more than 81 per cent. of residue, Bi_2O_3 . Arsenic limit, 2 parts per million. It complies with the limit tests for lead, copper, silver, chloride, sulphate, and alkalis and alkaline earths in Bismuthi Carbonas. It dissolves completely in an equal quantity of warm nitric acid without effervescence (limit of carbonate and insoluble matter).

Action and Uses.—Bismuth subnitrate differs from other salts of bismuth in that it is more astringent. It is used as a dusting powder and in the form of *Insufflatio Bismuthi et Morphinæ* for nasal catarrh. Bismuth subnitrate forms the principal constituent of Beck's pastes which are used for the radiographic detection of the course of fistulous tracts and for their treatment. Two pastes are used for injection into the fistula for these purposes: (a) for diagnosis and early treatment. Bismuth subnitrate, 30 parts; yellow soft paraffin, 60 parts; stir the powder slowly into the melted paraffin from which all water has been expelled. (b) for late treatment. Bismuth subnitrate, 30 parts; white wax, hard paraffin, of each, 5 parts; yellow soft paraffin, 60 parts. In some cases 1 per cent. of solution of formaldehyde is added. Care should be taken that no water is spilled into the pastes during heating. *Pasta Bismuthi et Iodoformi* is used as a dressing to promote the healing of wounds by first intention, but care must be taken to remove excess of the preparation.

Bismuth subnitrate is **administered** as powder or in cachets, but more frequently in mixtures, which may be thickened with syrup or glycerin. Addition of a gum as suspending agent should be avoided in mixtures containing bismuth subnitrate, unless its use is essential for some other reason, because gummy substances cause the insoluble salt to cohere and form indiffusible masses. A suitable vehicle for the administration of this and other salts of bismuth is compound infusion of orange. Bismuth subnitrate is **incompatible** with carbonates and bicarbonates; also with iodides, tannin and sulphur. If a mixture containing the subnitrate and a carbonate or bicarbonate is prescribed,

the two reacting salts should be rubbed together with warm water until the effervescence subsides before the mixture is completed.

Dose.—0·3 to 1·2 grammes (5 to 20 grains).

BISMUTH NITRATE, $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$, obtained by dissolving bismuth, or its oxide or carbonate, in nitric acid and crystallising, occurs in colourless, deliquescent crystals. It melts at 73° in its water of crystallisation and is decomposed at a higher temperature; it is soluble in a very small quantity of water, the addition of more water to this strongly acid solution causing separation of oxysalts. Bismuth nitrate is an astringent antiseptic used externally for certain skin diseases. For chapped and cracked hands, 10 to 60 grains of bismuth nitrate dissolved, without heat, in 1 fluid ounce of glycerin, forms a useful application.

Preparations

Insufflatio Bismuthi et Morphine, B.P.C.—(Insuff. Bism. et Morph.)—Bismuth and Morphine Insufflation. *Syn.*—Ferrer's Snuff; Bismuth and Morphine Snuff. Bismuth subnitrate, 75 per cent., and morphine hydrochloride, 0·4 per cent., with acacia.

Pasta Bismuthi et Iodoformi, B.P.C.—(Past. Bism. et Iodof.)—Bismuth and Iodoform Paste. *Syn.*—B.I.P.P. Bismuth subnitrate, 25 per cent., and iodoform, 50 per cent., with liquid paraffin.

Unguentum Resorcinolis Compositum, B.P.C.—(Ung. Resorcin. Co.)—Compound Resorcinol Ointment. *Syn.*—Unguentum Resorcini Compositum; Compound Resorcin Ointment. Resorcinol, 4 per cent., and bismuth subnitrate, 8 per cent., with distilled water, starch, zinc oxide, birch tar oil and potassium pyrosulphite, in wool fat, ceresin and yellow soft paraffin.

BISMUTHI TANNAS

(Bism. Tann.)

Bismuth Tannate

Bismuth tannate may be prepared by mixing freshly precipitated hydrated bismuth oxide with tannic acid and drying. It occurs as a brownish-yellow, odourless and tasteless powder.

Insoluble in water, alcohol and ether.

Standard.—Bismuth tannate yields on ignition, followed by re-ignition with a few drops of nitric acid, not less than 42 per cent. and not more than 47 per cent. of residue, Bi_2O_3 . Arsenic limit, 2 parts per million. 5 millilitre portions of the filtrate obtained by igniting 3 grammes, dissolving the residue in 4 millilitres of nitric acid, evaporating to half its volume and diluting to 100 millilitres with water, and then filtering, comply with the limit tests for lead, copper, silver, and alkalis and alkaline earths in Bismuthi Carbonas. 0·1 gramme treated with 1 millilitre of water and 5 millilitres of sulphuric acid, cooled, and 5 millilitres of ferrous sulphate solution carefully superimposed, shows no red or brown zone within five minutes (limit of nitrate).

Action and Uses. Bismuth tannate acts as an astringent and intestinal sedative and is used in the treatment of diarrhoea and dysentery. It is best **administered** in cachets or in glutoid capsules.

Dose.—0·3 to 2 grammes (5 to 30 grains).

BISMUTHI TRIBROMPHENAS

(Bism. Tribromphen.)

Bismuth Tribromphenate

Bismuth tribromphenate may be prepared by adding a solution of bismuth nitrate to a solution of the sodium salt of tribromophenol, filtering off the precipitate, and washing with alcohol. It occurs as a yellow, tasteless, nearly odourless, impalpable, neutral powder. It is not decomposed on heating at temperatures below 120° , but is decomposed by alkalis.

Insoluble in water, alcohol and ether.

Standard.—Bismuth tribromphenate, determined by the method for bismuth in Bismuthi Subchloridum after a preliminary decomposition with sodium hydroxide and solution of the separated precipitate in hydrochloric acid, contains not less than 40.5 per cent. and not more than 49.5 per cent. of Bi. When boiled with sodium hydroxide solution and the liquid acidified, a white, curdy precipitate of tribromophenol is produced which, when washed and dried, melts between 90° and 95° . Arsenic limit, 2 parts per million. 5 millilitre portions of the filtrate obtained by igniting 3 grammes, dissolving the residue in 4 millilitres of nitric acid, evaporating to half its volume and diluting to 100 millilitres with water and then filtering, comply with the limit tests for lead, copper, silver, and alkalis and alkaline earths in Bismuthi Carbonas. 0.01 gramme treated with 1 millilitre of water and 5 millilitres of sulphuric acid, cooled, and 5 millilitres of ferrous sulphate solution carefully superimposed, shows no red or brown zone within five minutes (limit of nitrate). On the addition of hydrochloric acid there is no effervescence (limit of carbonate). Shake 1 gramme with 30 millilitres of alcohol, filter and wash twice with 10 millilitres of alcohol, add excess of N/10 sodium hydroxide and titrate with N/10 hydrochloric acid, using phenolphthalein as indicator; the alcoholic solution requires not more than 1 millilitre of N/10 sodium hydroxide (limit of free tribromophenol).

Action and Uses.—Bismuth tribromphenate is a non-irritating and non-toxic antiseptic. It is given internally in gastro-intestinal catarrh, dysentery, infantile cholera, and diarrhoea. It has been recommended as a substitute for iodoform. It may be **administered** in cachets.

Dose.—0.3 to 1 gramme (5 to 15 grains).

BISMUTHI PHENAS.—Bismuth phenate may be prepared by adding slowly, with constant stirring, a solution of bismuth subnitrate in nitric acid diluted with water, to a solution of sodium hydroxide and phenol, the precipitate being washed with cold water and dried. It should contain at least 10 per cent. of phenol, but some samples examined have contained practically none. It occurs as a light, amorphous powder which is insoluble in water or alcohol. Bismuth phenate has been used as an intestinal antiseptic and occasionally as a dusting powder. Dose.—0.3 to 1.2 grammes (5 to 20 grains).

BISMUTHUM PRÆCIPITATUM

(Bism. Præcip.)

Precipitated Bismuth

Precipitated bismuth is finely divided metallic bismuth and may be prepared by the reduction of a solution of bismuth trichloride in hydrochloric acid by means of hypophosphorous acid. It occurs as a dull grey powder which is readily diffused when shaken with water and contains no particles larger than 15 microns in diameter.

Insoluble in water.

Standard, B.P.—Precipitated bismuth contains not less than 98·5 per cent. of metallic bismuth. Arsenic limit, 10 parts per million. It complies also with the limit tests for impurities in Bismuthi Carbonas.

Action and Uses.—Bismuth and its compounds are among the few drugs which are effective in the treatment of syphilis, neurosyphilis, cardiovascular syphilis and congenital syphilis. There is general agreement that bismuth is not so potent as the arsphenamines, but many consider that it exercises a more favourable influence than mercury. In certain cases of active syphilis in which the arsphenamines have proved ineffective, bismuth has often a beneficial effect. It may also be administered in cases in which injections of arsphenamines are not tolerated. It is accepted by most workers that the combination of arsphenamines and bismuth is more powerful as an anti-syphilitic than any other combination. Bismuth and mercury should not be used concurrently in the same case as they act in a similar manner on the tissues and are apt to produce intolerance and side-effects such as stomatitis and nephritis.

Bismuth does not act so rapidly as the arsphenamines in killing the organism of syphilis in the early stages of infection; this may be due to the fact that it is administered intramuscularly and as a result is more slowly absorbed. Continued administration of bismuth results in the disappearance of the primary sore of syphilis, the skin lesions on the surface of the body and on the mucous membranes, and the later manifestations of syphilis on the skin and elsewhere. It exercises a beneficial effect on the serological reactions (Wassermann test) of the blood in most cases of syphilis and especially in the earlier cases. If administered before the Wassermann reaction has become positive, that is, in serum-negative syphilis, and if its administration is continued over a sufficiently long period and in therapeutic doses, very few cases will develop a positive reaction in the blood. In this respect it is apparently more powerful than mercurial preparations. The effect of bismuth on the positive Wassermann reaction is variable; if given alone it does not produce a negative reaction so rapidly as the arsphenamines, but is more rapid than the action of any mercurial preparation whether the latter is administered intravenously or intramuscularly. The most efficient and most rapid method of altering a strong positive

reaction is the concurrent administration of arsphenamine and bismuth. Arsphenamine and mercury are also efficient if administered concurrently, but are not so well tolerated.

Old and debilitated patients and those suffering from cardiovascular syphilis and enfeebled circulation, tolerate bismuth better than the arsphenamines, and in these cases its action does not appear so depressing as that of mercury. If administered in therapeutic doses and with appropriate intervals between each dose to allow for the elimination of the drug, it gives rise to few toxic symptoms. The chief toxic manifestations are gingivitis and stomatitis; these may be obviated by attending to the hygiene of the mouth from day to day during its administration. The first evidence of toxicity is a slight metallic taste and the appearance of a blue line at the junction of the tooth and the alveolar margin of the gum. If a rest from treatment is given for one or two weeks and sodium thiosulphate is administered intravenously in 10 per cent. solution (3 to 10 millilitres), the further advance of the gingivitis can be arrested. Bismuth stomatitis and gingivitis are rarely so severe as those due to mercury and are more easily controlled. Other toxic effects which may eventuate from continued bismuth treatment are albuminuria, urticarial eruptions, mild erythemata and loss of weight. These complications are rare if appropriate intervals are allowed between the successive doses.

In general, it may be said that bismuth, when administered intramuscularly, is less toxic than the arsphenamines administered intravenously or intramuscularly, and less toxic and painful than the administration of mercury. Bismuth administration can be continued for long periods with comparative safety. The average dose of precipitated bismuth is from 0.1 to 0.4 gramme per week. The best medium in which to suspend it is isotonic dextrose solution. It may be **administered** intramuscularly as *Injectio Bismuthi*, but should never be given intravenously since by this route it gives rise to toxic symptoms. Aqueous preparations of precipitated bismuth for **injection** may be sterilised by heating in an autoclave or by tyndallisation. Suspensions in oil may be prepared with olive oil or almond oil which has been sterilised by heating at 150° for one hour and allowed to cool. The final container is sterilised by heating at 100° for thirty minutes.

Dose.— 0.1 to 0.2 gramme ($1\frac{1}{2}$ to 3 grains), by intramuscular injection.

Preparation

Injectio Bismuthi, B.P.—(Inj. Bism.)—Injection of Bismuth. A sterile preparation containing precipitated bismuth, 20 per cent. w/v, with dextrose and cresol in re-distilled water. 1 millilitre contains 0.2 gramme, and 15 minims contains about 3 grains, of precipitated bismuth. **Dose.**— 0.5 to 1 millilitre (8 to 15 minims), by intramuscular injection.

effloresces, and becomes anhydrous on ignition. It gives the colouration with turmeric paper described under boric acid, and a mixture of borax, sulphuric acid and alcohol burns with a flame tinged with green.

Soluble in water (1 in 25), boiling water (2 in 1) and glycerin (1 in 1); insoluble in alcohol (90 per cent.).

Standard, B.P.—Borax contains not less than 99 per cent. and not more than the equivalent of 103 per cent. of $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$. Arsenic limit, 5 parts per million. Lead limit, 5 parts per million. It complies also with limit tests for chloride, sulphate and iron.

Action and Uses.—Borax is a mild antiseptic, its action in this respect resembling that of boric acid, and it also possesses slight antacid properties. It is used **internally** alone, but generally in combination with the bromides, in cases of epilepsy. It is administered in mixtures flavoured with syrup of orange, and in lozenges and pastilles. Applied **externally**, borax has a sedative action and, as a lotion, is used for inflammatory conditions of the skin. It also exercises a cleansing effect upon the scalp when used as a hair wash. Compresses of a saturated solution are useful in the treatment of gouty affections. It is employed in gargles for aphthæ and stomatitis, in lotions for pruritus ani, for forced sweating (1 in 40) and for inflammatory conditions of the eye (1 in 100). Glycerinum Boracis is used as a paint for the tongue and throat, especially in children; Mel Boracis is applied to the mouth in aphthous conditions. Borax is **incompatible** with mucilage of acacia and precipitates many alkaloids, including cocaine, from solutions of their salts. Its use as a food preservative is now prohibited. Borax is preferable to sodium carbonate for preparing solutions for sterilising surgical instruments by boiling. It is also used as an insecticide.

Dose.—0.3 to 1 gramme (5 to 15 grains).

Preparations

Glycerinum Boracis, B.P.—(Glycer. Borac.)—Glycerin of Borax. Borax, 12 per cent. w/w, dissolved in glycerin. It has an acid reaction. **Dose.**—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Liquor Alkalinus, B.P.C.—(Liq. Alk.)—Alkaline Solution. *Syn.*—Collunarium Alkalinum; Alkaline Nasal Wash. Sodium bicarbonate and borax, of each 1.5 per cent. w/v, with phenol and sucrose in distilled water.

Liquor Boracis Compositus, B.P.C.—(Liq. Borac. Co.)—Compound Solution of Borax. *Syn.*—Collunarium Acidæ Carbolicæ Compositum; Dobell's Solution. Borax and sodium bicarbonate, of each, 1.5 per cent. w/v, with phenol, glycerin and distilled water.

Mel Boracis, B.P.—(Mel. Borac.)—Honey of Borax. *Syn.*—Borax Honey; Borax and Honey. Borax, 10 per cent. w/w, dissolved in glycerin and purified honey.

Pulvis Boracis Compositus, B.P.C.—(Pulv. Borac. Co.)—Compound Borax Powder. *Syn.* Pulvis Alkalinus Compositus; Compound Alkaline Powder. Sodium bicarbonate, sodium chloride and borax, equal parts.

Pulvis Sodii Chloridi Compositus, B.P.C.—(Pulv. Sod. Chlorid. Co.)—Compound Powder of Sodium Chloride. Sodium bicarbonate, sodium chloride, borax and sucrose, equal parts.

Solvellæ Antisepticæ, B.P.C.—(Solv. Antisep.)—Antiseptic Solution-Tablets. *Syn.*—Effervescing Mouth-wash Tablets. Each tablet contains 3 grains of borax with sodium benzoate, boric acid, menthol, oil of eucalyptus, thymol, oil of lemon, saccharin and lactose, with sodium bicarbonate and tartaric acid, and coloured with eosin and carmine.

Solvellæ Boracis Compositæ, B.P.C.—(Solv. Borac. Co.)—Compound Solution-Tablets of Borax. Each tablet contains 5 grains of borax, $2\frac{1}{2}$ grains of sodium chloride, $\frac{1}{10}$ grain of thymol and $2\frac{1}{2}$ grains of sodium bicarbonate.

Solvellæ Boracis et Benzaminæ Compositæ, B.P.C.—(Solv. Borac. et Benzamin. Co.)—Compound Solution-Tablets of Borax and Benzamine. *Syn.*—Naso-Pharyngeal Solution-Tablets. Each tablet contains 5 grains of sodium chloride, 3 grains of borax, 1 grain of boric acid, $\frac{1}{2}$ grain of sodium benzoate and $\frac{1}{2}$ grain of benzamine hydrochloride, with menthol, thymol and oil of sweet birch.

Solvellæ Boracis et Cocainæ Compositæ, B.P.C.—(Solv. Borac. et Cocain. Co.)—Compound Solution-Tablets of Borax and Cocaine. Each tablet contains 5 grains of sodium chloride, 3 grains of borax, 1 grain of boric acid, $\frac{1}{2}$ grain of sodium benzoate and $\frac{1}{2}$ grain of cocaine hydrochloride, with menthol, thymol and oil of sweet birch.

Tabellæ Potassii Chloratis et Boracis, B.P.C.—(Tab. Pot. Chlorat. et Borac.)—Tablets of Potassium Chlorate and Borax. Each tablet contains 3 grains of potassium chlorate and 2 grains of borax. Dose.—1 or 2 tablets.

BROMOFORMUM

(Bromof.)

Bromoform

Bromoform is tribromomethane containing about 4 per cent. of alcohol and may be prepared by the action of bromine, in the presence of an alkali, on ethyl alcohol, industrial methylated spirit or acetone. It is decomposed by light and air, and the addition of a little alcohol acts as a preservative. Bromoform occurs as a colourless, heavy liquid, with an odour resembling that of chloroform, and a sweetish taste. It is not inflammable, but the vapour introduced into a bunsen flame produces a green colour. It should be **stored** protected from light.

Soluble in water (1 in 800) and glycerin (about 1 in 80); miscible with alcohol, ether, benzene, fixed and volatile oils.

Standard.—Bromoform has a specific gravity of about 2.63. Residue on evaporation, not more than 0.05 per cent. Not more than 10 per cent. w/w distils below 147° , and the remainder between 148° and 155° . On shaking 10 millilitres of bromoform with 10 millilitres of water, and allowing to separate, the aqueous layer is neutral to litmus (limit of free acid), does not show more than a slight opalescence with silver nitrate solution (limit of bromides and other bromine compounds), and does not develop a blue colour on the addition of solution of potassium iodide and mucilage of starch (limit of free bromine). When shaken with an equal volume of sulphuric acid for ten minutes both the acid and the bromoform remain colourless.

Action and Uses.—Bromoform, although possessing general anæsthetic properties similar to those of chloroform, is not sufficiently volatile for inhalation. It is used chiefly in whooping cough and may be **administered** in the form of elixir, compound syrup, or dissolved in oil in capsules. On account of its high density and low solubility in water, bromoform is not satisfactory for exhibition in aqueous liquids, but it may be dissolved in oil and emulsified with acacia. Cases of **poisoning** in children have resulted from the use of bromoform; the symptoms closely resemble those of chloroform poisoning, but they are more prolonged. In such cases the stomach pump should be used and artificial respiration resorted to if necessary; although the symptoms are alarming, they are seldom followed by fatal results.

Dose.—0.03 to 0.12 millilitres ($\frac{1}{2}$ to 2 minims).

Preparations

Elixir Bromoformi, B.P.C.—(Elix. Bromof.)—Bromoform Elixir. *Syn.*—Mistura Bromoformi Composita; Compound Mixture of Bromoform. Bromoform, 1 in 50, with alcohol (90 per cent.), tincture of orange, compound tincture of cardamom and glycerin. *Dose.*—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Syrupus Bromoformi Compositus, B.P.C.—(Syr. Bromof. Co.)—Compound Syrup of Bromoform. Each fluid drachm contains about $\frac{1}{4}$ minim of bromoform, $\frac{1}{8}$ grain of codeine and $\frac{1}{4}$ minim of tincture of aconite, with spirit of bitter almond, alcohol (90 per cent.), cherry-laurel water, glycerin, syrup of red poppy and syrup of tolu. *Dose.*—4 to 16 millilitres (1 to 4 fluid drachms).

BROMUM

(Brom.)

Bromine

Br = 79.92

Bromine is a liquid non-metallic element which does not occur free in nature. It is chiefly obtained from the saline deposits of Stassfurt in Europe and from the brines of Virginia and Michigan in America. It occurs as a dark red-brown, heavy, mobile liquid, giving off brown fumes with an intensely irritating odour. Specific gravity, about 3.14. Bromine should be handled with great care since it causes severe burns and blisters when brought into contact with the skin. It should be **stored** in glass-stoppered bottles, in a cool place.

Soluble in water (1 in 30, by weight); readily soluble in alcohol, ether, chloroform, carbon disulphide and glycerin, with gradual decomposition of the solvents.

Standard.—Bromine contains not less than 99 per cent. of Br. Arsenic limit, 5 parts per million. A solution of 0.3 gramme in 10 millilitres of water, when shaken with 1 gramme of reduced iron until nearly colourless and filtered, does not develop a blue colour on the addition of 1 millilitre of starch mucilage and 1 millilitre of ferric chloride solution and allowing to stand for ten minutes (limit of iodine). 3 grammes

combines with 50 millilitres of sodium hydroxide solution to form a permanently clear liquid without the separation of oily drops (limit of organic bromine compounds). Dissolve 1 gramme in 10 millilitres of solution of ammonia and add 65 millilitres of water followed by 25 millilitres of nitric acid; bring to vigorous boiling and completely expel the bromine by passing a rapid current of air through the solution for twenty minutes while cooling; the residual liquid requires not more than 1.4 millilitres of N/10 silver nitrate for complete precipitation (limit of chloride).

Assay.—Weigh accurately about 0.2 gramme into 35 millilitres of potassium iodide solution, titrate with N/10 sodium thiosulphate using starch mucilage as indicator, and correct for the amount of chloride present as determined in the limit test for chloride; each millilitre of N/10 sodium thiosulphate is equivalent to 0.007992 gramme of Br.

Action and Uses.—Bromine closely resembles chlorine in its action and is a powerful disinfectant owing to its oxidising properties. It is not given internally in the uncombined state. **Externally** it has been used as a lotion for chronic ulcers in the proportion of 30 minims to 1 pint of water. In cases of **poisoning**, milk, white of egg or starch mucilage should be given.

BRYONIA

(Bryon.)

Bryony

Synonym—English Mandrake.

Bryony is the root obtained from *Bryonia dioica* Jacq. or *B. alba* Linn. (Fam. Cucurbitaceæ), climbing plants with perennial roots, growing in hedges and thickets in England and the European continent. It is collected in the autumn and is used both in the fresh or dried condition.

The fresh root is usually large and nearly cylindrical, generally simple, but occasionally branching into two, the diameter at the upper extremity being from 5 to 15 centimetres. Externally, it is greyish-yellow and marked at close intervals with prominent, transverse, corky ridges often extending half round the root, giving it a wrinkled appearance. Internally, it is white and fleshy, exuding, when cut, a juice which appears milky from the presence of numerous, minute starch grains. The transversely cut surface exhibits a fine line, the cambium, separating a narrow bark from a large parenchymatous xylem, which contains small groups of vessels arranged in concentric zones. The fresh root has an unpleasant odour, and an acrid and bitter taste; the dried root is odourless, but has a similar taste. When dried, the root is usually cut transversely to form disc-shaped pieces which are about 5 centimetres in diameter and 5 millimetres in thickness; they are hard and brittle

and have a thin, yellowish-grey cork and a whitish ring of porous wood, marked with concentric rings.

Bryony contains an amorphous, brownish-yellow, bitter, alkaloidal principle, and a dark brown, viscid resin, of which the dried root contains about 2 per cent., and from which can be isolated a phytosterol, a dihydric alcohol (bryonol), and a mixture of fatty acids. Other constituents are an essential oil, an amorphous, bitter glycoside which yields a brown resin on hydrolysis, a crystalline neutral substance, and an enzyme which slowly hydrolyses the glycosidal constituent, and can also effect the hydrolysis of amygdalin and salicin. The fresh root contains about 75 per cent. of moisture.

Standard.—Bryony contains not more than 2 per cent. of foreign organic matter.

Action and Uses.—Bryony is administered as *Tinctura Bryoniæ* to allay cough in pleurisy and phthisis; large doses are purgative in action. In cases of **poisoning** the stomach should be emptied and demulcent drinks given, the patient being kept warm.

BLACK BRYONY is the fresh root of *Tamus communis* Linn (Fam. Dioscoreaceæ); this root is smaller, dark brown externally, and free from bitterness.

Preparation

Tinctura Bryoniæ, B.P.C.—(Tinct Bryon.)—Tincture of Bryony. 1 in 10. Dose.—0.06 to 0.6 millilitre (1 to 10 minims).

BUCHU

(Buchu)

Buchu

Synonyms.—Buchu Folia; Buchu Leaves.

Buchu consists of the dried leaves of *Barosma betulina* (Thunb.) Bartl. and Wendl. (Fam. Rutaceæ), a small, shrubby plant indigenous to Cape Colony. The leaves are collected while the plant is flowering and fruiting.

The leaves vary in length from 12 to 20 millimetres; they are bright green to yellowish-green in colour, rigid, coriaceous, and rhomboid-ovate in outline. The margin is sharply denticulate in the apical half but serrulate in the basal half, an oil gland being situated at the base of each indentation; oil glands are also scattered throughout the mesophyll, giving rise to small prominences upon the surface, which is glabrous except at the base and upon the short petiole which bear a few unicellular trichomes. The apex is blunt, strongly recurved and contains an oil gland. The odour is strong and characteristic, especially when the leaves are crushed; the taste is strong and aromatic.

The diagnostic **microscopical** characters are the polygonal, straight-walled, epidermal cells of both surfaces, containing mucilage, which stains with ruthenium red, and sphæro-crystalline masses of diosmin;

the short, conical, unicellular, thick-walled, warty trichomes; the oil glands and idioblasts of the mesophyll, the latter containing cluster-crystals of calcium oxalate; the stomata on the lower surface only, some of them exceeding 38 microns in length (distinction from *B. crenulata* and *B. serratifolia*).

Buchu **contains** about 1·3 to 2 per cent. of volatile oil which, on cooling, deposits about 30 per cent. of diosphenol, $C_{10}H_{16}O_2$, a crystalline and optically inactive substance, boiling at 232° with partial decomposition; other constituents of the oil are *d*-limonene, dipentene and menthone. The drug also contains mucilage and yellow sphaerocrystals of diosmin. It yields to alcohol (20 per cent.) from 22 to 26 per cent. of extractive.

Substitutes.—In addition to the “short” or “round” buchu from *B. betulina*, two other varieties of the drug are imported, viz., “long” buchu and “oval” buchu. “Long” buchu leaves [*B. serratifolia* (Curt.) Willd.] may be distinguished by their greater length (2·5 to 3·0 centimetres), linear-lanceolate shape, serrate margin, and truncate apex; they contain numerous oil glands, one being situated in the apex. The constituents are similar to those of the official variety, with the exception that they contain no diosphenol; “oval” buchu leaves [*B. crenulata* (Linn.) Hook.] are rather broader than the “long” buchu, varying in outline from lanceolate to oval-oblong; the apex is not recurved. They yield about 1·6 per cent. of volatile oil which, like that of buchu, contains diosphenol. Leaves of other species of *Barosma* are occasionally imported and offered as buchu, one of the more important being *B. Bathu* Dummer, the leaves of which have a thickened, crenate margin and an apex which is devoid of an oil gland.

Standard, B.P.—Buchu contains not more than 5 per cent. of its stems and not more than 2 per cent. of other foreign organic matter. Ash, not more than 5 per cent.

Buchu, in powder (Pulvis Buchu: Pulv. Buchu), contains the constituents and possesses the diagnostic microscopical characters of Buchu, and complies with the limit for ash of the unground drug.

Action and Uses.—Buchu is a diuretic and urinary antiseptic; it is used principally in inflammatory conditions of the urinary organs such as cystitis, pyelitis, vesical irritation and gonorrhœa. It is **administered** with other diuretics and genito-urinary antiseptics, notably the citrates, acetates, benzoates, hexamine and cubeb. It is given preferably in the form of fresh infusion; the liquid extract is preferable to the tincture when only a small quantity of alcohol is desired.

Dose.—1 to 2 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ drachm).

Preparations

Extractum Buchu Liquidum, B.P.C.—(Ext. Buchu Liq.)—Liquid Extract of Buchu. 1 in 1. Dose.—0·3 to 1·2 millilitres (5 to 20 minims).

Infusum Buchu Concentratum, B.P.—(Inf. Buchu Conc.)—Concentrated Infusion of Buchu. Buchu, 1 in $2\frac{1}{2}$, extracted with alcohol (25 per cent.). This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh infusion of buchu and differs also in containing a small proportion of alcohol. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

A concentrated infusion, prepared with dilute chloroform water, alcohol (90 per cent.) and tincture of buchu, was included in the British Pharmaceutical Codex, 1923.

Infusum Buchu Recens, B.P.—(Inf. Buchu Rec.)—Fresh Infusion of Buchu. 1 in 20. Dose.—30 to 60 millilitres (1 to 2 fluid ounces).

Tinctura Buchu, B.P.C.—(Tinct. Buchu)—Tincture of Buchu. 1 in 5. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Thus tincture was included in the British Pharmacopœia, 1914.

BUTEÆ GUMMI

(But. Gum.)

Butea Gum

Synonym—Bengal Kino.

Butea gum is a dried, astringent juice obtained from incisions made in the stem of *Butea frondosa* Roxb. (Fam. Leguminosæ), a tree indigenous to India.

The gum occurs in small, irregular, angular fragments, to one side of which dull, buff-coloured portions of the cork and cortex of the stem sometimes adhere. When fresh it is brittle, vitreous, ruby-red in colour, and transparent in small fragments, but on keeping it becomes tougher, dull, opaque and nearly black; it is readily reduced to a reddish powder. The taste is astringent. It is partially **soluble** in water and yields about 40 per cent. to alcohol, the solution being scarcely coloured. The chief constituent is kinotannic acid.

Action and Uses.—Butea gum possesses astringent properties and may be used for similar purposes to kino. It is used in India and the Eastern Colonies as a substitute for East Indian, Malabar, Madras or Cochin kino.

BUTEÆ SEMEN

(But. Sem.)

Butea Seed

Synonym—Palas-papra.

Butea seed consists of the seeds of *Butea frondosa* Roxb. (Fam. Leguminosæ), a tree indigenous to India.

The seeds are flat and reniform, from 25 to 38 millimetres long, 16 to 25 millimetres wide and 1.5 to 2 millimetres thick; the seed coat is dark reddish-brown in colour, thin, glossy-veined and wrinkled, enclosing two large, yellowish, leafy cotyledons; the hilum is conspicuous and situated near the middle of the concave edge of the seed. The odour is faint and the taste slightly acid and bitter.

Butea **contains** about 18 per cent. of fixed oil, 19 per cent. of albuminoid substances and sugars. The ash averages about 5 per cent.

Action and Uses.—Butea seed possesses aperient properties and is used in India and the Eastern Colonies as an anthelmintic in the form of Pulvis Buteæ Seminum which is prepared by soaking the seed in distilled water, carefully removing the integuments, drying and powdering the kernels.

Dose.—0·6 to 1·2 grammes (10 to 20 grains).

BUTYLCHLORALIS HYDRAS

(Butylchloral. Hydr.)

Butylchloral Hydrate

Synonym—Croton-chloral Hydrate.

Butylchloral hydrate is trichlorobutylidene glycol, $\text{CH}_3\cdot\text{CHCl}\cdot\text{CCl}_2\cdot\text{CH}(\text{OH})_2$, and may be obtained by passing dry chlorine into aldehyde or paraldehyde cooled to about -10° , until the aldehyde is saturated, and then continuing the current of chlorine and gradually increasing the temperature to about 100° . The product is washed with sulphuric acid, submitted to fractional distillation, and the portion distilling at 163° to 165° collected. This is mixed with one-ninth its weight of water, and the solidified mass crystallised from boiling water. It occurs in pearly-white, trimetric laminæ, with a pungent, but not acrid, odour and a nauseous, bitter taste. Melting-point, about 78° , forming a clear liquid which commences to solidify at about 71° . Globules of butylchloral alcoholate are precipitated from a solution in alcohol by the gradual addition of water.

Soluble in water (1 in 40), glycerin (1 in 1 by weight), alcohol (5 in 3) with combination, chloroform (1 in 20), olive oil (1 in 20) and ether (1 in 2).

Standard.—Butylchloral hydrate yields not more than 0·05 per cent. of ash. The aqueous solution (2 per cent. w/v) is neutral or only slightly acid to litmus and gives no precipitate or opalescence with silver nitrate solution (limit of chloride). 0·5 gramme gently heated with 10 millilitres of sodium hydroxide solution and 3 drops of a saturated aqueous aniline solution, gives a mixture which, when shaken well and heated to boiling, does not develop the odour of phenylisocyanide (limit of chloral hydrate).

Action and Uses.—Butylchloral hydrate resembles chloral hydrate in its action although it is a weaker hypnotic and has a stronger depressant action on the heart. It may be used in place of chloral hydrate for sleeplessness not accompanied by pain. It is employed, often with camphor, phenazone, or gelsemium, as an analgesic for facial neuralgia or migraine. It is **administered** in mixtures, pills, or in cachets. It is **incompatible** with alkalis and alkaloids, and should not be dissolved in

alcohol with which it forms a water-insoluble alcoholate. In cases of **poisoning**, the procedure described under Chloralis Hydras should be followed.

Dose.—0.3 to 1.2 grammes (5 to 20 grains).

CAFFEINA

(Caffein.)

Caffeine

Caffeine, methyltheobromine or 1:3:7-trimethylxanthine, is an alkaloid present in tea, coffee beans and kola seeds. It is prepared chiefly from tea waste or coffee and may be obtained synthetically from guanidine, or by methylating theobromine. When crystallised from water, caffeine contains one molecule of water of crystallisation, but it is anhydrous when crystallised from alcohol, chloroform, or ether. Caffeine occurs in colourless, silky, glistening needles, usually matted together. It is odourless and has a bitter taste. Caffeine is a very weak base, which is decomposed by strong solutions of caustic alkalis; its salts are decomposed by water, and an aqueous solution of the alkaloid itself is neutral to litmus. It effloresces on exposure to dry air and loses its water of crystallisation on being heated, becoming anhydrous at 100°; it sublimates at about 180°.

When a trace of caffeine is moistened with bromine water or treated with a crystal of potassium chlorate and moistened with hydrochloric acid, and the mixture evaporated to dryness, a reddish residue is obtained which changes to purple on exposure to ammonia vapour (murexide reaction). Caffeine gives no precipitate with potassium-mercuric iodide solution and is distinguished thereby from most other alkaloids except theobromine and theophylline. On the addition of tannic acid solution it yields a white precipitate soluble in excess of the reagent. No precipitate forms on the addition of N/10 iodine to an aqueous solution of caffeine, but on acidifying the mixture with a few drops of hydrochloric acid a brown precipitate is produced.

Soluble in water (1 in 80), boiling water (1 in 1), alcohol (90 per cent.) (1 in 40), chloroform (1 in 7), ether (1 in 400) and benzene; its solubility in water is increased by the addition of sodium benzoate or sodium salicylate.

Standard, B.P.—Caffeine, after drying at 100°, has a melting-point of 235° to 237°. Loss on drying at 105°, not more than 8.5 per cent. Ash, not more than 0.1 per cent. It complies also with limit tests for readily carbonisable substances and for other alkaloids.

Action and Uses.—Caffeine exerts three important actions—(1) on the central nervous system, (2) on muscle, including cardiac, (3) on the

kidneys. The action on the central nervous system is mainly on that part of the brain connected with psychical functions. It produces a condition of wakefulness and increased mental activity. The interpretation of sensory impressions is more perfect and correct, and thought becomes clearer and more rapid. With larger doses of caffeine the action extends from the psychical areas to the motor area and to the cord, and the patient becomes at first restless and noisy, and later may show convulsive movements. Caffeine facilitates the performance of all kinds of physical work, and actually increases the total work which can be obtained from a muscle. In the normal man, however, it is impossible to say how much of the action on the muscle is central and how much is peripheral, but, as fatigue shows itself first by an action on the centre, it is probable that the action of caffeine in diminishing fatigue is mainly central. Caffeine accelerates the pulse and slightly raises the blood pressure. It has no action in any way resembling that of digitalis; by increasing the irritability of cardiac muscle its prolonged use tends rather to fatigue than to rest the heart. Caffeine, theobromine and theophylline form a very important group of diuretics. The urine is generally of a lower specific gravity than normal, since it contains a lower proportion of salts and urea, but the total excretion of solids both as regards urea, uric acid and salts is increased. Caffeine, by exciting the medulla, produces an initial vasoconstriction of the kidneys, which tends at first to retard the flow of urine. On this account other drugs such as theobromine and theophylline which act on the kidneys in a similar manner, but are without the stimulant action on the brain, are usually preferred.

Caffeine has been recommended as an antidote to nicotine. It is employed as a cardiac and renal stimulant in cardiac failure, chronic nephritis and general dropsy, but is contra-indicated in acute renal inflammation. It is of great value in nervous headache and migraine, and is often given with acetanilide, acetylsalicylic acid, or phenacetin. It is frequently effectual in relieving the paroxysms of asthma. Caffeine is **administered** in the form of powders, cachets and tablets. Compound powders of caffeine with codeine, amidopyrine, phenacetin, quinine, or magnesium oxide are frequently prescribed. For hypodermic injection, caffeine and sodium benzoate or caffeine and sodium salicylate is commonly employed. In cases of **poisoning** by caffeine, an emetic should be administered, followed by the free use of stimulants and the application of warmth to the extremities. Morphine and atropine may be given hypodermically.

Dose.—0·12 to 0·3 gramme (2 to 5 grains).

Preparations

Pulvis Acetanilidi Compositus, B.P.C.—(Pulv. Acetanilid. Co.)—Compound Acetanilide Powder. Acetanilide, 7 parts; caffeine, 1 part; sodium bicarbonate, 2 parts. Dose.—0·2 to 0·3 gramme (3 to 5 grains).

Tabellæ Acetanilidi Compositæ, B.P.C.—(Tab. Acetanilid. Co.)—Compound Tablets of Acetanilide. Each tablet contains 2 grains of acetanilide, $\frac{1}{4}$ grain of caffeine and 1 grain of sodium bicarbonate. Dose.—1 or 2 tablets.

Tabellæ Acetanilidi Compositæ cum Codeina, B.P.C.—(Tab. Acetanilid. Co. c. Codein.)—Compound Tablets of Acetanilide with Codeine. Each tablet contains 2 grains of acetanilide, $\frac{1}{2}$ grain of caffeine, 1 grain of sodium bicarbonate and $\frac{1}{2}$ grain of codeine. Dose.—1 or 2 tablets.

Tabellæ Acidi Acetylsalicylici Compositæ, B.P.C.—(Tab. Acid. Acetylsalicyl. Co.)—Compound Tablets of Acetylsalicylic Acid. *Syn.*—Compound Aspirin Tablets. Each tablet contains $3\frac{1}{2}$ grains of acetylsalicylic acid, $2\frac{1}{2}$ grains of phenacetin and $\frac{1}{2}$ grain of caffeine. Dose.—1 or 2 tablets

Tabellæ Acidi Acetylsalicylici et Caffeini, B.P.C.—(Tab. Acid. Acetylsalicyl. et Caffein.)—Tablets of Acetylsalicylic Acid and Caffeine. Each tablet contains 4 grains of acetylsalicylic acid and 1 grain of caffeine. Dose.—1 to 3 tablets.

Tabellæ Phenacetini Compositæ, B.P.C.—(Tab. Phenacet. Co.)—Compound Phenacetin Tablets. Each tablet contains 4 grains of phenacetin and 1 grain of caffeine. Dose.—1 or 2 tablets.

CAFFEINÆ CITRAS

(Caffein. Cit.)

Caffeine Citrate

Caffeine citrate is prepared by mixing 100 parts of caffeine with 100 parts of citric acid, moistening with 16 parts of distilled water and drying on a water-bath with constant stirring. It occurs as a white, odourless powder, having a bitter and acid taste, and an acid reaction. With three parts of water it forms a stiff paste which, if gently warmed, becomes a clear solution, and on cooling forms an almost solid mass of acicular crystals of caffeine. Treated with a crystal of potassium chlorate and a few drops of hydrochloric acid and evaporated to dryness, the residue is reddish and acquires a purple colour when exposed to the vapour of ammonia. A mixture of mercuric sulphate solution and a dilute solution of caffeine citrate heated to boiling produces a white precipitate on the addition of potassium permanganate solution.

Soluble in hot water (1 in 4), but dissociating on the further addition of water with separation of caffeine, which redissolves in 32 parts of water; soluble in alcohol (1 in 22) and in a mixture of 2 parts of chloroform and 1 part of alcohol (1 in 10).

Standard.—Caffeine citrate yields not less than 46 per cent. and not more than 51 per cent. of anhydrous caffeine, $\text{C}_8\text{H}_{10}\text{O}_2\text{N}_4$, calculated on the substance dried at 80° . Loss on drying at 80° , not more than 5 per cent. Ash, not more than 0.1 per cent.

Assay.—Dissolve about 1 gramme, accurately weighed, in 50 millilitres of water, add 10 millilitres of N/1 sodium hydroxide and extract the alkaloid with successive portions of chloroform until, on evaporating 1 millilitre of the chloroform extract, no residue remains. Wash the combined chloroform extracts with 2 millilitres of water, evaporate the chloroform and dry the residue of anhydrous caffeine at 100° .

Action and Uses.—Caffeine citrate has an action similar to that of the alkaloid. It may be **administered** in the form of effervescent granules or in cachets. Its solution contains free citric acid and therefore effervesces with alkali carbonates; it should be prescribed with acids rather than with alkalis. It is **incompatible** with a mixture of potassium iodide and spirit of nitrous ether, also with phenazone, sodium salicylate, benzoate, or nitrite. Caffeine alkaloid should be used for mixtures containing these substances.

Dose.—0·12 to 0·6 gramme (2 to 10 grains).

Preparations

Caffeinæ Citras Effervescens, B.P.C.—(Caffein. Cit. Efferv.)—Effervescent Caffeine Citrate. About 1 in 25. Dose.—4 to 8 grammes (1 to 2 drachms).

Effervescing caffeine citrate contains the same proportion of caffeine citrate as the corresponding preparation of the British Pharmacopœia, 1914, which was prepared with caffeine citrate, 4 grammes; tartaric acid, 27 grammes; citric acid, 18 grammes; sodium bicarbonate, 51 grammes; sucrose, 14 grammes.

Phenacetinum cum Caffeina Effervescens, B.P.C.—(Phenacet. c. Caffein. Efferv.)—Effervescent Phenacetin with Caffeine. Phenacetin, about 1 in 20, and caffeine citrate, about 1 in 60. Dose.—4 to 8 grammes (1 to 2 drachms).

Phenazonum cum Caffeina Effervescens, B.P.C.—(Phenazon. c. Caffein. Efferv.)—Effervescent Phenazone with Caffeine. *Syn.*—Effervescent Antipyrin with Caffeine. Phenazone, about 1 in 12, and caffeine citrate, about 1 in 60. Dose.—4 to 8 grammes (1 to 2 drachms).

Tabellæ Phenacetini et Caffeinæ Citratis, B.P.C.—(Tab. Phenacet. et Caffein. Cit.)—Tablets of Phenacetin and Caffeine Citrate. Each tablet contains 4 grains of phenacetin and 1 grain of caffeine citrate. Dose.—1 or 2 tablets.

CAFFEINA ET SODII BENZOAS

(Caffein. et Sod. Benz.)

Caffeine and Sodium Benzoate

Caffeine and sodium benzoate is a mixture of caffeine with sodium benzoate, and may be prepared by mixing equal weights of caffeine and sodium benzoate, moistening with either water or alcohol, and drying. It occurs in the form of a white, odourless powder, having a slightly bitter taste and a neutral reaction. It gives the reactions of caffeine and of sodium benzoate, and the former sublimes on the cooler portions of the tube when caffeine and sodium benzoate is heated cautiously in a dry tube. The caffeine can be extracted from the aqueous solution by adding sodium hydroxide and shaking with chloroform.

Soluble in water (1 in 4), warm water (about 1 in 1), part of the caffeine separating when the solution is cooled; slightly soluble in alcohol (90 per cent.).

Standard, B.P.—Caffeine and sodium benzoate contains not less than 47 per cent. and not more than 50 per cent. of anhydrous caffeine, $C_8H_{10}O_2N_4$, and not less than 50 per cent. and not more than 53 per cent. of sodium benzoate, $C_7H_5O_2Na$, both being calculated on the

substance dried at 105°. Loss on drying at 105°, not more than 5 per cent. The separated caffeine has a melting-point of 235° to 237° and the separated benzoic acid has a melting-point of 121° to 122°. It complies also with a limit test for acidity or alkalinity.

Action and Uses.—Caffeine and sodium benzoate is used hypodermically on account of its being readily soluble. Solutions of 1 part in 2 parts or more of sterilised water are used as a cardiac and respiratory stimulant or as a diuretic; a solution for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration.

Dose.—0.3 to 1 gramme (5 to 15 grains), by the mouth; 0.12 to 0.3 gramme (2 to 5 grains), by injection.

CAFFEINA ET SODII SALICYLAS

(Caffein. et Sod. Salicyl.)

Caffeine and Sodium Salicylate

Caffeine and sodium salicylate is a mixture of caffeine with sodium salicylate and may be prepared by triturating equal weights of the two ingredients with sufficient water or alcohol to form a smooth paste and drying. It occurs in the form of an odourless, white, amorphous powder or granular mass, having a sweetish, bitter taste. Heated in a test-tube the salt evolves white vapours having the odour of phenol. A strong aqueous solution gives a crystalline precipitate of salicylic acid on the addition of hydrochloric acid; a diluted solution gives a violet colouration with ferric chloride (distinction from caffeine and sodium benzoate). The anhydrous caffeine obtained in the assay complies with the tests for identity described under Caffeina.

Soluble in water (1 in 1), and in alcohol (1 in 28).

Standard.—Caffeine and sodium salicylate, determined by the methods of the British Pharmacopœia for caffeine and for sodium benzoate in Caffena et Sodii Benzoas, contains not less than 47 per cent. and not more than 50 per cent. of anhydrous caffeine, $C_8H_{10}O_2N_4$; and not less than 50 per cent. and not more than 53 per cent. of sodium salicylate, $C_7H_5O_3Na$, both being calculated on the substance dried at 105°; each millilitre of N/10 sodium hydroxide is equivalent to 0.01600 gramme of $C_7H_5O_3Na$. Loss on drying at 100°, not more than 5 per cent. It complies with the limit test for acidity or alkalinity for Caffena et Sodii Benzoas.

Action and Uses.—Caffeine and sodium salicylate is used hypodermically in place of caffeine, being much more soluble than the alkaloid. Solutions containing 1 part in 2 or more parts of sterilised water are used as a cardiac and respiratory stimulant, or as a diuretic. Solutions of caffeine and sodium salicylate for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration.

Dose.—0·3 to 1 gramme (5 to 15 grains), by the mouth; 0·12 to 0·3 gramme (2 to 5 grains), by injection.

CAFFEINÆ SALICYLAS.—Caffeine salicylate, $C_8H_{10}O_2N_4 \cdot C_7H_8O_3$, occurs as a white, crystalline powder which is less soluble in water than caffeine. It is useful in migraine associated with gout and rheumatism. **Dose.**—0·06 to 0·3 gramme (1 to 5 grains).

CAFFEINÆ HYDROBROMIDUM

(Caffein. Hydrobrom.)

Caffeine Hydrobromide

Caffeine hydrobromide may be prepared by dissolving caffeine in excess of warm, dilute hydrobromic acid, crystallising by careful evaporation, draining the resulting crystals and finally drying. It occurs in the form of large, transparent, colourless crystals, becoming coloured on exposure to the air, and losing part of its water of crystallisation. At 100° it becomes anhydrous, losing at the same time part of the hydrobromic acid; at 110° all the hydrobromic acid is driven off and caffeine remains.

Soluble in water (1 in 50), with decomposition into hydrobromic acid and caffeine; it is similarly decomposed by alcohol.

Standard.—Caffeine hydrobromide, determined by the method for Caffeinæ Citras, yields not less than 60 per cent. and not more than 63 per cent. of anhydrous caffeine, $C_8H_{10}O_2N_4$. Ash, not more than 0·1 per cent. Arsenic limit, 10 parts per million. Lead limit, 10 parts per million. 1 gramme complies with the limit test for sulphates.

Action and Uses.—Caffeine hydrobromide is employed principally in migraine and nervous headaches. It is **administered** in mixtures with potassium or sodium bromide, or in cachets.

Dose.—0·06 to 0·25 gramme (1 to 4 grains).

CAFFEINÆ IODIDUM.—Caffeine iodide, $C_8H_{10}O_2N_4 \cdot I_2 \cdot HI \cdot H_2O$, occurs in the form of prismatic crystals, having a metallic lustre, steel-blue by reflected light, red by transmitted light, and is readily decomposed in moist air or by heating on a water-bath. By boiling with water, iodine is removed, and, on evaporation, crystals of hydriodide are formed. It is soluble in water, with slow decomposition, and in alcohol. Caffeine iodide is useful in gout and rheumatism and has been prescribed for relieving the paroxysms of asthma. **Dose.**—0·06 to 0·2 gramme (1 to 3 grains).

CAFFEINÆ VALERIANAS.—Caffeine valerianate, $C_8H_{10}O_2N_4 \cdot C_5H_{10}O_2$, occurs in the form of white crystals or powder, having a strong odour of valerian. The salt is very unstable and very easily decomposed, losing part of its valerianic acid even on drying, and is soluble in alcohol with decomposition. Commercially, however, it is generally a mixture of caffeine and valerianic acid in varying proportions, the best preparation of the kind being a combination of the two anhydrous

substances in the proportions of 4 and 1, respectively. Caffeine valerianate is used to relieve headache in hysterical conditions and is administered in pills. **Dose.**—0·06 to 0·2 gramme (1 to 3 grains).

CALAMINA

(Calamin.)

Calamine

Synonyms—Calamina Præparata; Prepared Calamine.

Calamine is a basic zinc carbonate, with or without the addition of zinc oxide, suitably coloured with iron oxide. It is an amorphous, impalpable, pinkish powder, the shade depending upon the amount of iron oxide present and the process by which it is incorporated. When strongly heated it loses water and carbon dioxide, leaving a residue of zinc and iron oxides.

Insoluble in water.

Standard.—Calamine yields on ignition not less than 68 per cent. and not more than 90 per cent. of residue. It dissolves almost completely in warm, dilute hydrochloric acid, leaving not more than 1 per cent. of residue (limit of insoluble matter). Shaken with water and filtered, the filtrate is colourless (absence of water-soluble dyes). Dissolve 2 grammes in 20 millilitres of water and 5 millilitres of glacial acetic acid; the solution remains clear on the addition of 5 drops of potassium chromate solution (limit of lead). Dissolve 1 gramme in 10 millilitres of water and 2·5 millilitres of glacial acetic acid; no turbidity is produced on the addition of ammonium oxalate solution (limit of calcium and soluble barium salts).

Action and Uses.—Calamine is a common constituent of dusting powders, lotions and ointments, and is used as a mild astringent for roughness and redness of the skin and irritable eczematous conditions. The colour of calamine lotions may be varied for individual requirements by the addition of small quantities of suitable colouring matter. Linimentum Calaminæ is a soothing application in eczema and irritable conditions of the skin, and is sometimes used in place of carron oil for burns. Lotio Calaminæ is a useful application for relieving the pain and swelling caused by sunburn.

Preparations

Linimentum Calaminæ, B.P.C.—(Lin. Calamin.)—Liniment of Calamine. Calamine, about 1 in 25, and zinc oxide, about 1 in 30, with wool fat, oleic acid, liquid paraffin and solution of calcium hydroxide.

Linimentum Calaminæ Compositum, B.P.C.—(Lin. Calamin. Co.)—Compound Liniment of Calamine. Calamine, 1 in 10, with zinc oxide, zinc oleostearate, wool fat, white soft paraffin and liquid paraffin.

Lotio Calaminæ, B.P.C.—(Lot. Calamin.)—Calamine Lotion. Calamine, 1½ in 10, and zinc oxide, 1 in 20, with glycerin and rose water.

Unguentum Calaminæ, B.P.C.—(Ung. Calamin.)—Calamine Ointment. Calamine, about 16·5 per cent., in yellow soft paraffin.

CALAMUS

(Calam.)

Calamus*Synonyms*—Calamus Rhizome; Sweet Flag Root.

Calamus is the dried rhizome of *Acorus Calamus* Linn. (Fam. Araceæ), a plant indigenous to Eastern Europe and Central Asia, but widely diffused by cultivation, growing wild in England. The rhizome is collected in the autumn, trimmed, and sometimes scraped or peeled.

The rhizome occurs in sub-cylindrical pieces from about 5 to 15 centimetres long and about 1 to 2 centimetres in diameter. The unpeeled rhizomes are covered with a thin, brownish epidermis, and are much shrunken and deeply wrinkled longitudinally; they bear, on the upper surface, large, encircling, triangular leaf-scars and, on the under surface in irregular zigzag lines, closely approximated, raised, circular root-scars. The scraped rhizome is of a pale brownish-buff colour, and the scars are less conspicuous. Calamus breaks with a short, mealy fracture and is nearly white, starchy and spongy internally. The transversely cut surface shows a large stele separated from the cortex by the endodermis, which is evident as a yellowish line. The whole transverse surface exhibits numerous small, scattered, vascular bundles. The odour is sweet and aromatic, and the taste is bitter and pungent.

Calamus **contains** a bitter, aromatic, volatile oil which is present to the extent of 1.5 to 3.5 per cent. The drug also contains starch, tannin, and a bitter, amorphous principle, acorin, which yields acoretin by oxidation. The chief aromatic constituent of the volatile oil is asaryl alcohol; eugenol, asarone and other bodies have also been identified. Calamus yields to alcohol (70 per cent.) about 20 per cent. of extractive.

Action and Uses.—Calamus has the action of an aromatic bitter. On account of the volatile oil which is present it also acts as a carminative, removing the discomfort caused by flatulence. It is used to increase the appetite and benefit digestion, and may be **administered** in the form of infusion (Infusum Calami, 1 to 10; dose, $\frac{1}{2}$ to 1 fluid ounce) or tincture (Tinctura Calami, 1 in 5; dose, $\frac{1}{2}$ to 1 fluid drachm).

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

CALCI ACETYLSALICYLAS

(Calc. Acetylsalicyl.)

Calcium Acetylsalicylate

Calcium acetylsalicylate, $(\text{CH}_3\text{CO}\cdot\text{OC}_6\text{H}_4\cdot\text{COO})_2\text{Ca}, 2\text{H}_2\text{O}$, may be prepared by suspending calcium hydroxide in alcohol and adding acetylsalicylic acid, when the salt separates as a coagulated mass, which is washed with alcohol and dried at 40° to 60°. It occurs as a

white, non-hygroscopic powder. In aqueous solution it becomes hydrolysed, with formation of calcium salicylate and acetic acid. It decomposes rapidly in moist air and should be **stored** in well-stoppered containers.

Soluble in water (1 in 6) and alcohol (1 in 800).

Standard.—Calcium acetylsalicylate, determined by the method of the British Pharmacopœia for *Calcii Lactas*, contains not less than 95 per cent. of $C_{18}H_{14}O_8Ca, 2H_2O$; 1 gramme of residue is equivalent to 3.190 grammes of $C_{18}H_{14}O_8Ca, 2H_2O$. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million.

Action and Uses.—The action of calcium acetylsalicylate is essentially that of acetylsalicylic acid. On account of its gradual hydrolysis in aqueous solutions it is best **administered** in powders or cachets. It is incompatible with mineral acids, iron and quinine salts, carbonates, phosphates and sulphates. Calcium acetylsalicylate has also been used by intravenous injection in the treatment of rheumatic affections.

Dose.—0.3 to 1 gramme (5 to 15 grains).

CALCII BROMIDUM

(Calc. Brom.)

Calcium Bromide

Calcium bromide may be prepared by neutralising calcium carbonate with hydrobromic acid, or by the action of calcium hydroxide on solution of iron bromide. The hexahydrate, $CaBr_2, 6H_2O$, which crystallises from aqueous solution, is converted into the dihydrate, $CaBr_2, 2H_2O$, by heating to about 180° . It occurs as a white, or nearly white, odourless, very deliquescent, granular salt having a sharp saline and bitter taste. It melts and decomposes at a red heat with evolution of bromine. It should be **stored** in well-stoppered bottles.

Soluble in water (10 in 3) and alcohol (5 in 3).

Standard.—Calcium bromide, determined by the method of the British Pharmacopœia for *Potassii Bromidum*, contains not less than 98 per cent. of $CaBr_2, 2H_2O$; each millilitre of N/10 silver nitrate is equivalent to 0.0118 gramme of $CaBr_2, 2H_2O$. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. It complies with the limit test for chloride in *Potassii Bromidum*. Pour 1 millilitre of dilute sulphuric acid on 1 gramme of the powdered salt; no yellow colour is produced immediately (limit of bromate). A solution of 1 gramme with 1 gramme of sodium acetate, slightly acidified with acetic acid, after boiling, cooling, and shaking with a few drops of potassium dichromate solution, does not appear opalescent within five minutes (limit of barium).

Action and Uses.—Calcium bromide has been recommended in epilepsy and chorea as a substitute for potassium bromide. Its rate of absorption is relatively slow. It is **administered** in solution, being too deliquescent for use in powders or cachets. The salt is incompatible with alkali carbonates, phosphates and sulphates.

Dose.—0.5 to 2 grammes (8 to 30 grains).

CALCII CARBONAS

(Calc. Carb.)

Calcium Carbonate

Synonyms—*Calcii Carbonas Præcipitatus*; Precipitated Calcium Carbonate; Precipitated Chalk.

Calcium carbonate may be obtained by double decomposition between sodium carbonate and a soluble calcium salt. It occurs as a white, odourless and tasteless, microcrystalline powder. Grades of different densities are obtainable in commerce; the lightest grades are not microcrystalline.

Almost **insoluble** in water; slightly soluble in water containing carbon dioxide.

Standard, B.P.—Calcium carbonate contains not less than 98.5 per cent. of CaCO_3 , calculated on the substance dried at 100° . Loss on drying at 100° , not more than 1 per cent. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. It complies also with limit tests for aluminium, iron and matter insoluble in hydrochloric acid, soluble alkali, chloride, sulphate and iron.

Action and Uses.—Calcium carbonate is used **internally** in the same way as chalk, although the latter is sometimes preferred on account of its amorphous condition. It is used chiefly as a basis for tooth powders, its microcrystalline character conferring advantages over chalk for this purpose. A siliceous basis is, however, more suitable for tooth powders containing boric acid or phenol. Applied **externally**, calcium carbonate is antacid and protective, forming, when made into a cream with oil, a soothing application for burns. It is **administered** in cachets or powders and in the form of *Pulvis Bismuthi Compositus*, *Trochisci Alkalini Compositi*, or *Trochisci Antacidi*.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

Preparations

Creta cum Camphora, B.P.C.—(*Cret. c. Camph.*)—Camphorated Chalk. Camphor, 1 in 10, with calcium carbonate.

Pulvis Bismuthi Compositus, B.P.C.—(*Pulv. Bism. Co.*)—Compound Bismuth Powder. Bismuth carbonate, 1 part; calcium carbonate, 3 parts; heavy magnesium carbonate, 3 parts; sodium bicarbonate, 1 part. **Dose.**—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

Trochisci Alkalini Compositi, B.P.C.—(Troch. Alk. Co.)—Compound Alkaline Lozenges. Each lozenge contains 12 grains of compound bismuth powder.

Trochisci Antacidi, B.P.C.—(Troch. Antacid.)—Antacid Lozenges. Each lozenge contains $3\frac{1}{2}$ grains of calcium carbonate, $2\frac{1}{2}$ grains of heavy magnesium carbonate and 1 grain of sodium chloride.

CALCII CHLORIDUM

(Calc. Chlorid.)

Calcium Chloride

Calcium chloride may be prepared by the interaction of hydrochloric acid and calcium carbonate, the product being evaporated and dried at a temperature not exceeding 200° . It occurs in white granules or porous masses which are very deliquescent and have a warm, slightly bitter taste. Other varieties occurring in commerce are the two hydrated crystalline forms, $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$ and $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$, and "fused" calcium chloride which contains varying proportions of water. A crude form of calcium chloride is used in ice machines for the production of a solution of low freezing-point. Calcium chloride should be **stored** in well-closed containers.

Soluble in water (1 in 1.5) and alcohol (90 per cent.) (1 in 3).

Standard, B.P.—Calcium chloride contains not less than 98 per cent. of CaCl_2 , calculated on the substance dried at 200° . Loss on drying at 200° , not more than 10 per cent. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. It complies also with limit tests for free alkali, sulphate, and for aluminium, iron, phosphate and matter insoluble in hydrochloric acid.

Action and Uses.—Calcium is present in every normal body cell and is necessary for its proper functioning. On the breakdown of the mechanism that regulates the proper utilisation of the supply of calcium in the food and of the large available store in the bones, symptoms of calcium deficiency become apparent. In this condition, treatment with parathyroid extract, vitamin D, or ultra-violet light is often of greater value than the administration of calcium salts by the mouth. In conditions where calcium is necessary in abnormal quantity, such as in pregnancy and lactation, calcium should be administered in conjunction with a high vitamin intake. In exophthalmic goitre there is a considerable loss of calcium from the bones, and calcium salts should be administered. Calcium salts are also indicated in tetany; severe cases require parathyroid in addition. Laryngeal or bronchial spasm and convulsions may be treated by the intravenous injection of 20 millilitres (300 minims) of a 5 per cent w/v solution of calcium chloride. The intramuscular injection of 0.06 gramme (1 grain) of calcium chloride has been recommended for the treatment of laryngismus in children.

In the tetany of rickets or osteomalacia the use of parathyroid is contra-indicated, except in an emergency, since calcium is removed from the bones to increase the blood-calcium. The intravenous injection of calcium chloride has been advocated in the treatment of pulmonary tuberculosis. In the prevention of lead poisoning a high calcium diet is necessary. The toxic episodes of lead poisoning, namely, colic, palsy and meningo-encephalopathy, are urgent indications for calcium therapy, since calcium favours lead storage. On the other hand, the elimination of lead is accelerated by a low calcium diet, together with the administration of ammonium chloride. Caution is necessary, however, since lead is rapidly mobilised by this method; it should only be employed during a quiescent stage or severe manifestations of plumbism will occur. In severe cases of colic 15 millilitres (225 minims) of a 5 per cent. w/v solution of calcium chloride should be given intravenously. The effect on the pain is probably superior to that of any other therapeutic measure. The injection may be repeated after two hours. Renal colic and gallstone colic are amenable to the same treatment.

Administration of calcium is recommended in acute necrosis of the liver, such as in eclampsia, chloroform poisoning and poisoning from cinchophen, and in jaundice generally. A daily dose of 5 millilitres (75 minims) of a 10 per cent. w/v solution of calcium chloride is reported to have had good results in acne vulgaris. In asthma, urticaria, angio-neurotic œdema, serum disease and other allergic states, calcium is of value since it decreases the permeability of the capillary endothelium. It has long enjoyed a vogue in the treatment of chilblains. In chronic ulcerative conditions such as varicose ulcers, and also in gastric ulcer and in fractures, calcium appears to expedite the healing process. On account of its power to increase the coagulability of the blood, calcium chloride is used in hæmoptysis and purpuric eruptions to arrest hæmorrhage. Its use has also been advocated in post-influenzal debility as it increases the force of the heart. Since calcium chloride when given by mouth is somewhat irritating to the gastro-intestinal tract, calcium lactate is often prescribed instead. Calcium should be administered prior to operations in cases of jaundice and tonsillitis.

Calcium chloride is best **administered** in dilute solution flavoured with tincture of orange or simple elixir. Care is necessary when injecting strong solutions, and the injection should be made slowly. Solutions of calcium chloride for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. Occasionally calcium chloride is applied externally in dilute solutions to bleeding points, as a styptic. It is also added to Nauheim baths to increase their specific gravity; it is not absorbed through the skin. It is **incompatible** with soluble carbonates, phosphates, tartrates and sulphates.

Dose.—0.6 to 2 grammes (10 to 30 grains), by the mouth; 0.03 to 0.1 gramme ($\frac{1}{2}$ to $1\frac{1}{2}$ grains), by intramuscular injection; 0.3 to 1 gramme (5 to 15 grains), by intravenous injection.

Preparation

Syrupus Calcii Chloridi, B.P.C.—(Syr. Calc. Chlorid.)—Syrup of Calcium Chloride. *Syn.*—Elixir Calcii Chloridi; Elixir of Calcium Chloride. Calcium chloride, 1 in 8, with distilled water and syrup of lemon. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

CALCII ET SODII LACTAS

(Calc. et Sod. Lact.)

Calcium Sodium Lactate

Calcium sodium lactate, $\text{Ca}(\text{C}_3\text{H}_5\text{O}_3)_2\cdot 2\text{NaC}_3\text{H}_5\text{O}_3\cdot 4\text{H}_2\text{O}$, may be prepared by dissolving two equal parts of calcium lactate separately in water, precipitating one portion with the required amount of sodium carbonate, filtering off the calcium carbonate and then mixing the two clear solutions, when the double salt is obtained by evaporation. It occurs as a white powder or as colourless, hard granules, which melt when heated above 100° , and lose water of crystallisation on further heating. It is deliquescent when exposed to air. When aqueous solutions are warmed with potassium permanganate an odour of acetaldehyde is produced. It should be **stored** in well-closed containers.

Soluble in water (about 1 in 15) and boiling alcohol (about 1 in 10); insoluble in ether and benzene.

Standard.—Calcium sodium lactate contains not less than 8·5 per cent. and not more than 9·5 per cent. of Ca, and not less than 10 per cent. and not more than 11 per cent. of Na, both calculated on the substance dried at 130° . Loss on drying at 130° , not more than 16 per cent. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. 0·5 gramme with 1·5 millilitres of nitric acid complies with the limit test for chlorides. 0·5 gramme with 5 millilitres of hydrochloric acid complies with the limit test for sulphates. A solution of 5 grammes in hot water does not become pink on the addition of a few drops of phenolphthalein solution, and requires not more than 0·5 millilitre of N/1 sodium hydroxide to produce a pink colour (limit of acidity).

Assay.—For calcium. Weigh accurately about 1 gramme, dissolve in about 50 millilitres of water, add 5 millilitres of acetic acid and excess of ammonium oxalate solution and boil for thirty minutes, collect the precipitate, wash, dry, ignite, and titrate the residue with N/10 sulphuric acid, using methyl orange as indicator; each millilitre of N/10 sulphuric acid is equivalent to 0·002004 gramme of Ca.

For sodium. Weigh accurately about 1 gramme, ignite gently, and titrate the residue with N/10 sulphuric acid, using methyl orange as indicator; deduct the number of millilitres of N/10 sulphuric acid required in the assay for calcium; each millilitre of N/10 sulphuric acid is equivalent to 0·00230 gramme of Na.

Action and Uses.—Calcium sodium lactate has the same action as

calcium lactate, but is more soluble and easy of absorption. Its use is stated to be beneficial in the night-sweats of phthisis, hæmoptysis, difficult dentition and in certain types of dermatitis. It is usually **administered** in tablets.

Dose.—0.3 to 2 grammes (5 to 30 grains).

Preparation

Tabellæ Parathyroidei et Calcii et Sodii Lactatis, B.P.C.—(Tab. Parathyroid. et Calc. et Sod. Lact.)—Tablets of Parathyroid and Calcium Sodium Lactate. Each tablet contains $7\frac{1}{2}$ grains of calcium sodium lactate and $\frac{1}{10}$ grain of parathyroid. **Dose.**—1 to 4 tablets.

CALCII FORMAS

(Calc. Form.)

Calcium Formate

Calcium formate, $(\text{HCOO})_2\text{Ca}$, may be prepared by neutralising formic acid with calcium carbonate, and evaporating the solution, from which the calcium formate separates as a glistening crystalline crust, or in large crystals. It occurs in the form of anhydrous, rhombic crystals. In hot solution it reduces salts of silver and mercury. When treated with sulphuric acid, carbon monoxide is evolved, and when heated with calcium benzoate, benzaldehyde is formed together with calcium carbonate.

Soluble in water (1 in 8); insoluble in alcohol.

Standard.—Calcium formate contains not less than 98 per cent. of $\text{C}_2\text{H}_2\text{O}_4\text{Ca}$. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million.

Assay.—Dissolve about 0.8 gramme, accurately weighed, in 100 millilitres of water and to 10 millilitres of the solution add 3 millilitres of sodium carbonate solution; add 50 millilitres of N/10 potassium permanganate and allow to stand at 50° for fifteen minutes; add 50 millilitres of N/10 oxalic acid and 5 millilitres of sulphuric acid, heat to 60° and titrate with N/10 potassium permanganate. Carry out a control test, omitting the calcium formate, and subtract the result from the number of millilitres used in the final titration; each millilitre of N/10 potassium permanganate is equivalent to 0.003252 gramme of $\text{C}_2\text{H}_2\text{O}_4\text{Ca}$.

Action and Uses.—Calcium formate is employed for the supposed tonic action of the formic radicle upon striped and unstriped muscle when calcium salts are indicated. It is usually **administered** in cachets. Solutions of calcium formate for **injection** may be sterilised by filtration. It is **incompatible** with the alkali carbonates, phosphates, and sulphates.

Dose.—0.2 to 0.6 gramme (3 to 10 grains).

CALCII GLYCEROPHOSPHAS

(Calc. Glycerophosph.)

Calcium Glycerophosphate*Synonym*—Calcium Glycerylphosphate.

Calcium glycerophosphate, $\text{CaC}_3\text{H}_5(\text{OH})_2\text{PO}_4, 2\text{H}_2\text{O}$, may be prepared by adding glycerophosphoric acid to an excess of milk of lime, filtering when cold and washing with water. The filtrate, with added washings, is deprived of excess of lime by means of carbon dioxide, and concentrated to a low bulk, when the separated salt may be collected, or it may be completely precipitated by alcohol. Calcium glycerophosphate occurs as a white or creamy-white powder, consisting largely of hydrated calcium α -glycerophosphate. It may be rendered anhydrous by heating at 130° . It should be **stored** in well-stoppered bottles. Preparations containing a large proportion of the somewhat insoluble β -salt are sometimes sophisticated by the addition of citric acid, in order to render them soluble. Acid calcium glycerophosphate should not be used, since it becomes hydrolysed in aqueous solution and deposits calcium phosphate.

Soluble in cold water; almost insoluble in boiling water; insoluble in alcohol.

Standard.—Calcium glycerophosphate contains not less than 98 per cent. of $\text{C}_3\text{H}_7\text{O}_6\text{PCa}$, calculated on the substance dried at 130° . Loss on drying at 130° , not more than 15 per cent. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. 1 gramme dissolves in 50 millilitres of cold water with only a slight turbidity. Dissolve 0.5 gramme in 10 millilitres of water acidified with sulphuric acid, add 2 millilitres of mercuric sulphate solution, boil and, if necessary, filter while hot; the hot filtrate on the addition of potassium permanganate solution, drop by drop, does not produce a white precipitate (limit of citrate). When shaken with 25 parts of dehydrated alcohol and filtered, it yields, on evaporation of the alcohol and subsequent drying at 70° for one hour, not more than 1 per cent. of residue (limit of glycerin, etc.). A weight equivalent to 1 gramme of the salt dried at 130° , dissolved in 100 millilitres of water, requires for neutralisation to phenolphthalein not more than 2 millilitres of N/10 hydrochloric acid or N/10 sodium hydroxide (limit of alkalinity or acidity); the resulting solution requires not less than 9 millilitres of N/2 hydrochloric acid for neutralisation to methyl orange (minimum limit for glycerophosphate).

Assay.—Ignite about 0.5 gramme, accurately weighed, and weigh the residue; 1 gramme of the residue is equivalent to 1.653 grammes of $\text{C}_3\text{H}_7\text{O}_6\text{PCa}$.

Action and Uses.—Calcium glycerophosphate is used in the treatment of neurasthenia. It is a constituent of the compound syrups and glycerins of the glycerophosphates (see *Acidum Glycerophosphoricum*).

It may also be dispensed alone or in combination with iron glycerophosphate in cachets and may be given hypodermically in doses of 0·1 gramme ($1\frac{1}{2}$ grains). It is **incompatible** with carbonates, phosphates and sulphates.

Dose.—0·2 to 0·6 gramme (3 to 10 grains).

CALCII HYDROXIDUM

(Calc. Hydrox.)

Calcium Hydroxide

Synonym.—Calcii Hydras.

Calcium hydroxide, or slaked lime, is prepared by the action of water on calcium oxide. It occurs as a soft, white powder with an alkaline, slightly bitter taste. The aqueous solution has an alkaline reaction and readily absorbs carbon dioxide from the air. Calcium hydroxide dissolves in solutions of sugars with formation of calcium saccharosates. It should be **stored** in well-closed containers.

Slightly **soluble** in water (1 in 900); less soluble in hot water; more readily soluble in solutions of glycerin.

Standard, B.P.—Calcium hydroxide contains not less than 90 per cent. of Ca(OH)_2 . Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. It complies also with limit tests for aluminium, iron and matter insoluble in hydrochloric acid, chloride and sulphate.

Action and Uses.—Calcium hydroxide is antacid and astringent, and is usually administered in solution. It is used internally in the form of *Liquor Calcii Hydroxidi* as a mild antacid in the treatment of the diarrhoea and vomiting of infants. *Liquor Calcii Hydroxidi* is also frequently added to milk to prevent the formation of large clots of curd in the stomach and is employed **externally** as a skin lotion with calamine or zinc oxide. *Linimentum Calcii Hydroxidi cum Oleo Lini* is a popular remedy for application to burns and scalds. Various compound oily liniments are also used, in which a soap formed from solution of calcium hydroxide serves as the emulsifying agent.

Dose.—0·3 to 1 gramme (5 to 15 grains).

Preparations

Linimentum Calcii Hydroxidi, B.P.C.—(Lin. Calc. Hydrox.)—Liniment of Calcium Hydroxide. *Syn.*—*Linimentum Calcis*; *Liniment of Lime*. Solution of calcium hydroxide and olive oil, equal parts.

This liniment was included in the British Pharmacopœia, 1914, under the name of Linimentum Calcis.

Linimentum Calcii Hydroxidi cum Oleo Lini, B.P.C.—(Lin. Calc. Hydrox. c. Ol. Lini.)—Liniment of Calcium Hydroxide with Linseed Oil. *Syn.*—*Lime Water and Oil*; *Carron Oil*; *Linimentum Calcis cum Oleo Lini*. Solution of calcium hydroxide and linseed oil, equal parts.

Liquor Calcii Hydroxidi, B.P.—(Liq. Calc. Hydrox.)—Solution of Calcium Hydroxide. *Syn.*—Liquor Calcis, Solution of Lime; Lime Water. A saturated aqueous solution of calcium hydroxide. At 15.5° it contains not less than 0.15 per cent. w/v of Ca(OH)_2 . Arsenic limit, 0.2 part per million. Lead limit, 0.5 part per million. It complies also with a limit test for chlorides. It should be stored in completely-filled, well-closed containers. Dose.—30 to 120 millilitres (1 to 4 fluid ounces).

Liquor Calcii Hydroxidi Saccharatus, B.P.C.—(Liq. Calc. Hydrox. Sacch.)—Saccharated Solution of Calcium Hydroxide. *Syn.*—Liquor Calcis Saccharatus; Saccharated Solution of Lime. It contains the equivalent of not less than 2.4 per cent. w/v of Ca(OH)_2 with sucrose and distilled water. Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

This solution was included in the British Pharmacopœia, 1914, under the name of Liquor Calcis Saccharatus.

CALCIUM HYPOPHOSPHIS

(Calc. Hypophosph.)

Calcium Hypophosphite

Calcium hypophosphite, $\text{Ca(H}_2\text{PO}_2)_2$, may be obtained by heating phosphorus with milk of lime. When interaction is complete the solution is filtered and evaporated to dryness, or the salt is allowed to crystallise after concentration. It occurs as an odourless, white powder, or in lustrous crystals, having a nauseous and bitter taste. On heating, the salt decrepitates, and at 300° spontaneously inflammable gases are evolved. A solution acidified with hydrochloric acid gradually added to mercuric chloride solution produces a white precipitate which becomes grey when excess of the acid solution is added. It is a powerful reducing agent, its admixture with certain oxidising bodies, such as nitrates and chlorates, being attended with some danger. It should be **stored** in well-stoppered bottles.

Soluble in water (1 in 8); in boiling water slightly more so; insoluble in alcohol.

Standard.—Calcium hypophosphite contains not less than 98 per cent. of $\text{CaP}_2\text{H}_4\text{O}_4$. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. 1 gramme dissolved in 20 millilitres of water requires for neutralisation not more than 0.5 millilitre of N/10 sodium hydroxide, using phenolphthalein as indicator. Not more than 0.5 per cent. is insoluble in water (limit of phosphate). 1 gramme dissolved in 20 millilitres of water and filtered remains clear on the addition of an equal volume of calcium sulphate solution (limit of barium).

Assay.—Dissolve about 1.0 gramme, accurately weighed, in 100 millilitres of water. To 10 millilitres of the solution in a stoppered flask add 10 millilitres of 25 per cent. w/v sulphuric acid and 30 millilitres of N/10 iodine. Allow to stand in the dark for twelve hours and titrate the excess of iodine with N/10 sodium thiosulphate; each millilitre of N/10 iodine is equivalent to 0.004254 gramme of $\text{CaP}_2\text{H}_4\text{O}_4$.

Action and Uses.—Calcium hypophosphite is given in general debility, but the hypophosphite ion has no known specific action. It is commonly prescribed as *Syrupus Hypophosphitum Compositus*, or, if the presence of sugar is undesirable, as *Glycerinum Hypophosphitum Compositum* (see *Acidum Hypophosphorosum Dilutum*). It is also given in association with malt extract, with or without cod-liver oil, or with emulsion of cod-liver oil or liquid paraffin. Calcium hypophosphite, in common with other hypophosphites, is a powerful reducing agent and does not keep well in aqueous solution. Its oxidation, in solution, may be retarded by the addition of a little free hypophosphorous acid. It is **incompatible** with oxidising agents, and with iron and ammonium citrate.

Dose.—0·2 to 0·6 gramme (3 to 10 grains).

MAGNESII HYPOPHOSPHIS.—Magnesium hypophosphite, $\text{Mg}(\text{H}_2\text{PO}_2)_2 \cdot 6\text{H}_2\text{O}$, may be prepared by boiling magnesium oxalate with a solution of calcium hypophosphite, filtering the solution and allowing the salt to crystallise. It occurs in white crystals, soluble in water (1 in 5). **Dose.**—0·2 to 0·6 gramme (3 to 10 grains).

Preparation

Syrupus Calcii Hypophosphitis, B.P.C.—(*Syr. Calc. Hypophosph.*)—Syrup of Calcium Hypophosphite. Each fluid drachm contains 1 grain of calcium hypophosphite, with hypophosphorous acid, sucrose and distilled water. **Dose.**—4 to 16 millilitres (1 to 4 fluid drachms).

CALCII IODIDUM

(Calc. Iod.)

Calcium Iodide

Calcium iodide may be prepared by the action of calcium hydroxide on ferrous iodide, or by neutralising hydriodic acid with calcium hydroxide or carbonate, filtering, evaporating to dryness, and fusing. It occurs as a white, deliquescent mass or powder, which becomes yellow on keeping. It has a bitter taste. Calcium iodide should be **stored** in well-closed containers.

Very **soluble** in water and alcohol.

Standard.—Calcium iodide, determined by the method of the British Pharmacopœia for *Potassii Iodidum*, contains not less than 80 per cent. of CaI_2 ; each millilitre of *M*/20 potassium iodate is equivalent to 0·0147 gramme of CaI_2 . Arsenic limit, 5 parts per million. Lead limit, 20 parts per million.

Action and Uses.—Calcium iodide has the general properties of iodides and calcium salts.

Dose.—0·06 to 0·3 gramme (1 to 5 grains).

CALCII LACTAS

(Calc. Lact.)

Calcium Lactate

Calcium lactate, $(\text{CH}_3\cdot\text{CHOH}\cdot\text{COO})_2\text{Ca}, 5\text{H}_2\text{O}$, may be obtained by neutralising warm, diluted lactic acid with calcium carbonate, filtering while hot and crystallising. Large quantities are obtained as an intermediate product in the preparation of lactic acid. It occurs as a white powder with a slight but not unpleasant odour and a slight taste. It effloresces on exposure to air and becomes anhydrous when heated at 100° . Calcium lactate should be **stored** in well-closed containers.

Very slowly but completely **soluble** in water (1 in 18.5); readily soluble in hot water; slightly soluble in alcohol (90 per cent.); insoluble in ether.

Standard, B.P.—Calcium lactate contains not less than 97 per cent. and not more than the equivalent of 103 per cent. of $\text{C}_6\text{H}_{10}\text{O}_6\text{Ca}, 5\text{H}_2\text{O}$. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. It complies also with limit tests for alkalinity or acidity, various sugars, sulphate, chloride and iron.

Action and Uses.—Calcium lactate has the characteristic action of calcium (see Calcii Chloridum). It increases the coagulability of the blood, and is given before operations with this object, in doses of 1 to 2 grammes (15 to 30 grains). It is also used for chilblains and chronic ulcerations, in hæmophilia and some forms of albuminuria, and in rickets and tuberculous disease. It is much less irritating than calcium chloride, and may be injected subcutaneously. Calcium lactate, like other calcium salts, has probably little or no specific action when given orally, except in conjunction with the administration of vitamin D.

Calcium lactate is frequently **administered** in solution prepared directly from calcium carbonate and lactic acid (Liquor Calcii Lactatis). A solution containing about 100 grains of freshly prepared calcium lactate may be obtained by adding gradually 40 grains of calcium carbonate to 60 minims of lactic acid diluted with about ten times its volume of water and boiling the mixture for twenty minutes; the excess of calcium carbonate is then removed by filtration, the precipitate washed, and the mixed filtrate and washings diluted to the required volume. For chilblains, large doses should be given periodically for two or three days in preference to continuous administration.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

CALCII GLUCONAS.—Calcium gluconate is a white, crystalline powder, readily soluble in water. It is administered in all forms of calcium deficiency, either by the mouth in doses of 5 grammes (75 grains) three times a day, or intravenously in solution. The dose by injection is 1 gramme (15 grains) every day, on alternate days, or every third day.

CALCII LACTOPHOSPHAS.—Calcium lactophosphate may be prepared by mixing calcium carbonate, lactic acid, phosphoric acid and distilled water and

evaporating to dryness. It occurs as a white, hygroscopic, crystalline powder, soluble in water. Calcium lactophosphate is a stomachic tonic, especially useful for children. It is best administered in the form of *Syrupus Calcii Lactophosphatis*, which is pleasantly acid to the taste, or it may be combined with ferrous lactate as *Syrupus Calcii Lactophosphatis cum Ferro*. Dose.—0.2 to 0.5 gramme (3 to 8 grains).

MAGNESII LACTAS.—Magnesium lactate, $C_6H_{10}O_6Mg, 3H_2O$, occurs as a white, crystalline powder, which when heated decomposes without melting. It is soluble in water (1 in 30), boiling water (1 in 6), and insoluble in alcohol. Magnesium lactate may be used as a mild laxative. Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

MAGNESII LACTOPHOSPHAS.—Magnesium lactophosphate is a mixture of magnesium phosphate and magnesium lactate. It occurs as a white powder, soluble in water. Dose.—0.2 to 1 gramme (3 to 15 grains).

POTASSII LACTAS.—Potassium lactate, $C_3H_5O_3K$, occurs as a colourless or yellowish, syrupy liquid or as an amorphous mass. It is very hygroscopic, and soluble in water or alcohol, but insoluble in ether. Dose.—0.3 to 1 gramme (5 to 15 grains).

Preparations

Liquor Calcii Lactatis, B.P.C.—(Liq. Calc. Lact.)—Solution of Calcium Lactate. 15 millilitres contains about 0.7 gramme, and 4 fluid drachms contains about 10 grains, of calcium lactate dissolved in chloroform water. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Syrupus Calcii Lactophosphatis, B.P.C.—(Syr. Calc. Lactophosph.)—Syrup of Calcium Lactophosphate. Each fluid drachm contains calcium lactophosphate equivalent to about 4 grains of calcium lactate, with phosphoric acid, triple orange-flower water, sucrose and distilled water. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This syrup was included in the British Pharmacopæia, 1914.

Syrupus Calcii Lactophosphatis cum Ferro, B.P.C.—(Syr. Calc. Lactophosph. c. Ferr.)—Syrup of Calcium Lactophosphate with Iron. Each fluid drachm contains about $\frac{1}{2}$ grain of ferrous lactate with potassium citrate and distilled water in syrup of calcium lactophosphate. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tabellæ Parathyroidei et Calcii Lactatis, B.P.C.—(Tab. Parathyroid. et Calc. Lact.)—Tablets of Parathyroid and Calcium Lactate. Each tablet contains 5 grains of calcium lactate and $\frac{1}{10}$ grain of parathyroid. Dose.—1 to 4 tablets.

CALCII OXIDUM

(Calc. Oxid.)

Calcium Oxide

$CaO = 56.08$

Synonyms—Calx; Lime; Quicklime.

Calcium oxide may be obtained by calcining marble. It occurs as white or greyish-white masses which readily absorb water and carbon dioxide if exposed to the air. It is odourless, and has an alkaline reaction and a caustic, burning taste. When about half its weight of water is added, the mass swells, with the evolution of much heat, and falls to powder, producing calcium hydroxide, commonly known as slaked lime, the process being known as slaking. Water agitated with calcium oxide becomes alkaline to phenolphthalein. Milk of lime is

prepared by mixing 1 part of calcium oxide with 2 parts of water. Calcium oxide slaked with solution of sodium hydroxide, dried, and ignited to redness forms soda-lime. Calcium oxide should be **stored** in air-tight containers, in a dry place.

Standard.—Calcium oxide, determined by the method of the British Pharmacopœia for *Calcii Hydroxidum*, contains not less than 95 per cent. of CaO, calculated on the ignited substance; each millilitre of N/1 hydrochloric acid is equivalent to 0.02804 gramme of CaO. Loss on ignition, not more than 10 per cent. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. 1 gramme with 4 millilitres of nitric acid complies with the limit test for chlorides. 0.5 gramme with 2.5 millilitres of hydrochloric acid complies with the limit test for sulphates. Shake 2 grammes with 20 millilitres of water, add 10 millilitres of hydrochloric acid, boil, make alkaline with ammonia, filter and wash; the insoluble residue after ignition weighs not more than 0.02 gramme (limit of aluminium, iron and insoluble matter).

Action and Uses.—Calcium oxide is used in the preparation of caustic pastes such as *Pasta Londinensis*, which is a mixture of quick-lime with sodium hydroxide made into a paste with water at the time of using. Calcium oxide burns of the eyes may be treated by irrigation with a solution of neutral ammonium tartrate; ointment of trinitrophenol (1 in 50) has also been recommended.

CALCII PERMANGANAS

(Calc. Permang.)

Calcium Permanganate

Calcium permanganate, $\text{Ca}(\text{MnO}_4)_2, 5\text{H}_2\text{O}$, may be prepared by decomposing a solution of silver permanganate with calcium chloride, filtering off the precipitated silver chloride, evaporating the solution and allowing it to crystallise; or by first preparing a dilute solution of permanganic acid, and then neutralising it with calcium carbonate, concentrating the liquid and allowing to crystallise. It occurs as deliquescent, crimson crystals, or purplish-red, crystalline masses.

Very soluble in water.

Standard.—Calcium permanganate, determined by the method of the British Pharmacopœia for *Potassii Permanganas*, contains not less than 95 per cent. of $\text{CaMn}_2\text{O}_8, 5\text{H}_2\text{O}$; each millilitre of N/10 oxalic acid is equivalent to 0.00368 gramme of $\text{CaMn}_2\text{O}_8, 5\text{H}_2\text{O}$. Dissolve 1 gramme in 10 millilitres of hot water, decolourise by the addition of 4 grammes of oxalic acid, and add sufficient hydrochloric acid to produce

a clear solution; no colouration is produced on passing hydrogen sulphide into the solution (limit of heavy metals).

Action and Uses.—Calcium permanganate has the same action as the potassium salt, but is stated to be a more powerful antiseptic and to have a less disagreeable taste. It has been used internally in gastritis and gastric ulcer, also as a local application for rodent ulcer, inoperable offensive carcinoma and similar conditions. Doses of 0·016 gramme ($\frac{1}{4}$ grain) have been used for the treatment of thread-worm infection in children. Calcium permanganate is **administered** in capsules containing liquid paraffin or in pills massed with kaolin ointment.

Dose.—0·03 to 0·1 gramme ($\frac{1}{2}$ to $1\frac{1}{2}$ grains).

CALCI PEROXIDUM

(Calc. Perox.)

Calcium Peroxide

Calcium peroxide may be prepared by adding calcium hydroxide solution to a solution of hydrogen peroxide; the hydrated peroxide thus formed, $\text{CaO}_2\cdot 8\text{H}_2\text{O}$, becomes anhydrous on heating to about 130° . It occurs as a whitish powder. At a red heat it is rapidly decomposed into calcium oxide and oxygen, and is slowly decomposed, with evolution of oxygen, in the presence of water. In contact with glycerin or formaldehyde solution it is liable to form explosive mixtures. 0·01 gramme in 10 millilitres of water with 1 drop of dilute sulphuric acid, on the addition of a few millilitres of ether and a drop of potassium dichromate solution, produces a blue colour which passes into the ethereal layer after shaking.

Very slightly **soluble** in water.

Standard.—Calcium peroxide contains not less than 30 per cent. of CaO_2 .

Assay.—Shake about 0·2 gramme, accurately weighed, with 25 millilitres of water and 25 millilitres of dilute hydrochloric acid and titrate with N/10 potassium permanganate; each millilitre of N/10 potassium permanganate is equivalent to 0·003604 gramme of CaO_2 .

Action and Uses.—Calcium peroxide possesses antacid and antiseptic properties, and has been used as an intestinal disinfectant; it has also been employed in the treatment of digestive disturbances in children, especially in acid dyspepsia, being administered in milk. It is also used in dentifrices.

Dose.—0·2 to 0·5 gramme (3 to 8 grains).

CALCII PHOSPHAS

(Calc. Phosph.)

Calcium Phosphate

Calcium phosphate may be obtained by purifying bone ash or by the interaction of boiling solutions of calcium chloride and sodium phosphate in the presence of excess of ammonia. It consists chiefly of a mixture of dibasic calcium phosphate, CaHPO_4 , and tribasic calcium phosphate, $\text{Ca}_3(\text{PO}_4)_2$, together with some monobasic acid calcium phosphate, $\text{Ca}(\text{H}_2\text{PO}_4)_2$, but the proportions in which these occur are very variable. Calcium phosphate is sometimes supplied as tribasic calcium phosphate, but a pure tribasic or normal calcium phosphate is not obtainable. It occurs as a white, odourless, amorphous powder which is almost tasteless, and is stable in air.

Almost **insoluble** in water; soluble in dilute mineral acids.

Standard, B.P.—Calcium phosphate contains calcium equivalent to not less than 85 per cent. of $\text{Ca}_3(\text{PO}_4)_2$. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. It complies also with limit tests for carbonate and matter insoluble in hydrochloric acid, chloride, sulphate and iron.

Action and Uses.—Calcium phosphate forms three-fourths of the mineral matter in the body. It is contained mostly in the bones, to which it gives rigidity. Calcium phosphate is **administered** chiefly in the form of Syrupus Ferri Phosphatis Compositus for the treatment of general debility, rickets, etc. Syrup of calcium lactophosphate contains calcium phosphate in combination with lactic acid. Calcium phosphate is a useful antacid; it possesses the advantage over alkali hydroxides and carbonates of reducing the acidity in the stomach without producing systemic alkalisation. In the solid form, it may be given in powders, which may be taken in milk, or the powder may be dispensed in cachets. On account of its non-hygroscopic properties, it is sometimes used as a diluent of powders and extracts.

Dose.—0.6 to 2 grammes (10 to 30 grains).

CALCII SULPHAS EXSICCATUS

(Calc. Sulph. Exsic.)

Exsiccated Calcium Sulphate

Synonyms—Plaster of Paris; Sulphate of Lime; Calcined Gypsum.

Exsiccated calcium sulphate is prepared by carefully roasting natural gypsum, $\text{CaSO}_4, 2\text{H}_2\text{O}$. It occurs as a white, hygroscopic, odourless and tasteless powder. When mixed with a little water it forms a smooth paste which rapidly sets to a hard mass, but if completely dehydrated,

or heated above 200°, or if much hygroscopic moisture has been absorbed, it loses this property. The setting is retarded by adding a colloid or any substance which will decrease its solubility, and is accelerated by adding substances which increase its solubility. The following are said to be used: restrainers—alcohol, citric acid, althæa powder, dextrin, acacia, linseed mucilage, glue and sodium carbonate; accelerators—common salt and alum. It should be **stored** in a dry place in such a way as to protect it as far as possible from the action of moisture. Deterioration is indicated either by too rapid setting or by very slow setting, the set mass being more or less weakened and friable according to the degree of deterioration.

Slightly **soluble** in water; more soluble in dilute mineral acids; insoluble in alcohol.

Standard. 20 grammes of exsiccated calcium sulphate, mixed with 10 millilitres of water at 15° to 20° in a cylindrical mould about one inch in diameter, sets in about three minutes. The mass thus formed, after allowing to stand for three hours, possesses sufficient hardness to resist pressure of the fingers at the edges, which retain their sharpness of outline and do not crumble under pressure.

Uses.—The principal use of exsiccated calcium sulphate in pharmacy is for the preparation of plaster of Paris bandages. Extemporaneous bandages may be prepared by applying the exsiccated calcium sulphate thickly to a material such as check muslin or book muslin before rolling; after rolling, the whole is thoroughly moistened and wound round the limb. Alternatively, the exsiccated calcium sulphate may be mixed to a thin cream in a basin, and the unrolled bandaging material passed through the cream immediately before applying to the limb. The plaster will set and a splint form in from fifteen to twenty minutes; 1½ to 2 parts of water to 1 part of exsiccated calcium sulphate forms a suitable proportion, and a 5 per cent. solution of dextrin may be used in place of water. The bulk of the mass increases slightly as the plaster sets; interstices are thus filled and close application obtained.

Preparation

Ligamentum Calcii Sulphatis, B.P.C.—(Ligament. Calc. Sulph.)—Plaster of Paris Bandage. This bandage consists of bleached cotton cloth impregnated with exsiccated calcium sulphate and suitable adhesives.

CALENDULA

(Calend.)

Calendula

Synonyms—Marigold; Marigold Flowers.

Calendula consists of the dried, ligulate florets of *Calendula officinalis* Linn. (Fam. Compositæ), indigenous to the Levant and Southern

Europe, and now cultivated in England. When the flower-heads are fully expanded, the ray florets are collected and dried. It should be **stored** in a dry, cool place in closed containers.

The corollas are yellow or orange, about 12 to 35 millimetres long and 2.5 to 6 millimetres broad at the widest part, oblanceolate, terminating in three, sometimes two or four, acute teeth and having four veins. The tube of the corolla, about 1 millimetre long, is hairy, having two kinds of trichomes, the majority being long, bi-seriate and conical, while the remainder are shorter and end in a multicellular club-shaped head. The filiform style and bifid stigma are usually present and are accompanied by numerous, spherical, spiny pollen grains, about 30 to 35 microns in diameter, each showing 3 pores. The odour is slightly aromatic, and the taste bitter.

Calendula **contains** a tasteless, yellow substance, calendulin, a bitter principle and traces of an aromatic volatile oil. The drug yields to alcohol (90 per cent.) about 18 per cent. of extractive.

Standard.—Calendula contains not more than 2 per cent. of foreign organic matter.

Action and Uses.—Calendula was at one time believed to have the power of promoting the absorption of effused blood. It is a mild aromatic and possesses diaphoretic, diuretic and stimulant properties. It has been **administered** in the form of tincture in the treatment of amenorrhœa. The tincture, diluted with 10 to 20 parts of water, is used as a lotion, or with 10 parts of base as an ointment, for sprains and bruises.

Preparation

Tinctura Calendulæ, B.P.C.—(Tinct. Calend.) Tincture of Calendula. 1 in 5.

CALOTROPIS

(Calot.)

Calotropis

Synonyms—Calotropis Bark; Mudar.

Calotropis is the dried root-bark of *Calotropis procera* Ait. and of *C. gigantea* Ait. (Fam. Asclepiadaceæ), trees indigenous to India and Ceylon, the former indigenous also to tropical Africa.

The bark occurs in short, curved or, more rarely, quilled pieces 2 to 5 millimetres thick and 2 to 3.5 centimetres broad, and sometimes root-lets are attached. The outer surface is soft, pale buff and longitudinally furrowed and the inner surface is pale yellow and granular; the fracture is short and mealy. Portions of the wood are sometimes attached. The drug is odourless and has a bitter and acrid taste.

The diagnostic **microscopical** characters are the wide, irregular, corky layer; a broad, parenchymatous pericycle and an abundant

secondary phloem consisting largely of parenchyma, with closely arranged, inconspicuous medullary rays, one cell wide; the pericycle and phloem rich in starch, the starch grains being either simple, measuring from 3 to 10 microns in length, with a distinct hilum and conspicuous striations, or compound, usually with two components; laticiferous vessels anastomosing throughout the pericycle and phloem, which contain numerous rosette-crystals of calcium oxalate; the absence of fibres.

Calotropis **contains** a yellow, bitter resin, a black, acid resin, a crystalline, colourless substance (madaralban), an amber-coloured, viscid substance (madarfluavil), and caoutchouc.

Action and Uses.—Calotropis resembles ipecacuanha in its action; small doses are diaphoretic and expectorant, and large doses cause vomiting and diarrhoea. Tincture of calotropis (Tinctura Calotropis, 1 in 10; dose, $\frac{1}{2}$ to 1 fluid drachm) is used in India and the Eastern Colonies.

Dose.—Expectorant, 0.2 to 0.6 gramme (3 to 10 grains); emetic, 2 to 4 grammes ($\frac{1}{2}$ to 1 drachm).

CALUMBA

(Calumb.)

Calumba

Synonyms—Calumbæ Radix; Calumba Root.

Calumba consists of the dried, transverse or oblique slices of the root of *Jateorhiza palmata* (Lam.) Miers (Fam. Menispermaceæ), a climbing plant indigenous to Portuguese East Africa, and growing freely in forests near the Zambesi. The roots are dug up during the dry season, cut into slices and dried. The somewhat dull colour of the drug as imported is often brightened by a process of cleaning.

The slices of the root are irregularly circular or oval, depressed in the centre on both sides, usually about 2 to 6 centimetres in diameter and from 3 to 12 millimetres thick. They are of a more or less distinct yellow colour, the exterior being covered with a greyish-brown, longitudinally wrinkled cork. The transverse surface shows a dark cambium line separating the greenish-yellow outer region from the greyish inner region; the former is traversed by dark, sinuous strands of phloem and the latter shows concentric zones and radiating lines of yellowish xylem vessels. The fracture is short and starchy. The odour is slight, and the taste bitter.

The diagnostic **microscopical** characters are the isolated sclerenchymatous cells in the outer part of the bark, with yellow, unevenly thickened walls, and containing small prismatic crystals of calcium oxalate; the large reticulate vessels of the xylem, also yellow in colour and, like the sclerenchymatous cells, changing to green on treatment with 60

per cent. v/v sulphuric acid; the abundant starch grains mostly simple and about 20 to 85 microns in length, and having a well-marked, eccentric, radiate or cleft hilum.

Calumba contains columbamine, palmatine and jateorhizine, three yellow, crystalline alkaloids, closely allied to berberine. It also contains two colourless, crystalline principles, columbin and chasmantherin, and an abundance of starch. Tannin is not a normal constituent of the drug. It yields to alcohol (60 per cent.) about 15 per cent. of extractive.

Substitutes and Adulterants.—The drug often contains portions of the rhizome from which the roots spring; these may be recognised by their smaller size, the diameter being about 2 centimetres, the narrow cortex and conspicuously radiate wood with strongly developed lignified tissue, in consequence of which the centre of the slices is prominent instead of being depressed. Slices of *Coscium*, occasionally imported as Ceylon calumba, and of the root of *Fraseria carolinensis* Walt. (Fam. Gentianaceæ), indigenous to North America, have been used as adulterants or substitutes for calumba. The latter are smaller and thicker, and contain tannin but no starch.

Standard, B.P.—Calumba contains not more than 2 per cent. of foreign organic matter. Ash, not more than 9 per cent.

Calumba, in powder (*Pulvis Calumbæ*: *Pulv. Calumb.*), contains the constituents and possesses the diagnostic microscopical characters of Calumba, and complies with the limit for ash of the unground drug.

Action and Uses.—Calumba is a simple bitter, and is given before meals for its reflex action in dyspepsia associated with hypochlorhydria. Its preparations possess the advantage of being compatible with salts of iron. It is usually **administered** in the form of infusion or tincture.

Dose. 0·6 to 2 grammes (10 to 30 grains).

COSCINIUM.—Coscium consists of the dried stem of *Coscium fenestratum* Colebr (Fam. Menispermaceæ), common in India and Ceylon. It occurs in large, woody, cylindrical, straight pieces, sometimes as much as 10 centimetres in diameter. Externally, it is yellowish-brown in colour and longitudinally fluted or fissured, with smaller transverse fissures at intervals. Internally, it is yellow, the smoothed transverse surface exhibiting a large, yellow, conspicuously radiate xylem, porous wood-bundles alternating with dense medullary rays which are continued through the phloem, the latter tissue being lacunous from shrinkage away from the crenate ring of sclerenchyma immediately within the cortex. The fracture is short in the wood and fibrous in the bark. The drug has no odour, but a bitter taste. Coscium contains the yellow, crystalline alkaloid, berberine; it also contains a saponin. Coscium is a bitter used in India and the Eastern Colonies as an equivalent of calumba.

Preparations

Infusum Calumbæ Concentratum, B.P.—(*Inf. Calumb. Conc.*)—Concentrated Infusion of Calumba. Calumba, 1 in 2½, extracted with cold distilled water and preserved with alcohol. This concentrated infusion, when diluted with seven times its volume of distilled water, yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh infusion of calumba and differs also in containing a small proportion of alcohol. Dose 2 to 4 millilitres (½ to 1 fluid drachm).

A concentrated infusion, prepared with dilute chloroform water and alcohol (90 per cent), was included in the British Pharmaceutical Codex, 1923.

Infusum Calumbæ Recens, B.P.—(Inf. Calumb. Rec.)—Fresh Infusion of Calumba. 1 in 20. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Tinctura Calumbæ, B.P.—(Tinct. Calumb.)—Tincture of Calumba. 1 in 10, prepared by maceration with alcohol (60 per cent.). Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

CALX CHLORINATA

(Calx. Chlorinat.)

Chlorinated Lime

Synonym—Bleaching Powder.

Chlorinated lime is prepared by exposing slaked lime to the action of chlorine gas until absorption ceases. It is sometimes known as "chloride of lime." It occurs as a dull white powder with a characteristic odour differing somewhat from that of chlorine. On exposure to the air it becomes moist and decomposes, carbon dioxide being absorbed and chlorine evolved. It is decomposed by acids, with evolution of the "available chlorine" upon which its value depends. The stability of bleaching powder in tropical temperatures is increased by admixture with unslaked lime. Chlorinated lime should be **stored** in well-closed containers.

Partly **soluble** in water and alcohol (90 per cent.).

Standard, B.P.—Chlorinated lime contains not less than 30 per cent. w/w of available chlorine.

Action and Uses.—Chlorinated lime, by virtue of its available chlorine, is a powerful disinfectant and deodorant. It is used to disinfect faces, urine and, to some extent, rooms and houses. It has powerful bleaching properties and is capable of decolourising most dye-stuffs. Chlorinated lime and liquid chlorine are used to purify water for drinking purposes; they should be added in such amount as to leave 0.25 to 0.5 part of free chlorine in a million parts of water. They communicate, however, a distinct taste to the water. After chlorination for twenty-four hours a small amount of sodium pyrosulphite may be added to combine with any excess of chlorine.

Wounds are frequently treated by continuous irrigation with chlorine-containing solutions, and in order to obtain satisfactory results a continuous supply of the solution must be available, since the chlorine or hypochlorite is rapidly exhausted by interaction with the proteins of the inflamed area. A solution of chlorine is of great value as a local application in acute tonsillitis, for which purpose it is best used from a vulcanite spray. Liquor Calcis Chlorinatæ is used as a wash for foul ulcers, as a nasal or vaginal injection, or as a gargle in tonsillitis, but its usefulness is limited on account of its irritant action. Liquor Calcis Chlorinatæ cum Acido Borico (eusol) is used as a general antiseptic, but on account of its alkaline reaction it is not suitable for use in the Carrel-Dakin method of continuous irrigation of infected wounds.

It has been used for intravenous injection in cases of septicæmia, and for this purpose it should be rendered isotonic by the addition of 0.85 per cent. of sodium chloride. On account of the rapid combination with the plasma proteins, its action is evanescent. It is employed as a vaginal douche, diluted 1 in 80.

Liquor Sodæ Chlorinatæ Chirurgicæ (Dakin's solution) is one of the most stable and suitable forms of chlorinated solution for the continuous irrigation of infected wounds. Liquor Sodæ Chlorinatæ cum Sodii Bicarbonate (Daufresne's solution) was devised for the Carrel-Dakin treatment, and is also an efficient form of chlorinated antiseptic for general purposes. Liquor Sodæ Chlorinatæ (bleaching solution) is used as a general disinfectant and oxidising agent. Externally, it is used, diluted with 10 to 15 parts of water, as a lotion for ulcers and foul wounds, and as a gargle or spray solution in tonsillitis, scarlet fever and diphtheria. It is sometimes employed as a bleaching agent. Labarraque's solution is a solution of chlorinated soda, about one-fourth the strength of Liquor Sodæ Chlorinatæ. Eau de Javelle is a similar solution of chlorinated potash. A mixture of equal parts of chlorinated lime and boric acid (eupad) may be used as an application to septic areas or employed for the extemporaneous preparation of solutions of eusol.

Preparations

Liquor Calcis Chlorinatæ, B.P.C.—(Liq. Calc. Chlorinat.). Solution of Chlorinated Lime. An aqueous solution containing the soluble matter from 10 per cent. w/v of chlorinated lime; it contains not less than 2 per cent. w/v of available chlorine.

This solution was included in the British Pharmacopæia, 1914.

Liquor Calcis Chlorinatæ cum Acido Borico, B.P.C.—(Liq. Calc. Chlorinat. c. Acid. Boric.)—Solution of Chlorinated Lime with Boric Acid. *Syn.*—Eusol. It contains, when freshly prepared, about 0.4 per cent. of available chlorine.

Liquor Chlorig, B.P.C.—(Liq. Chlorig) Solution of Chlorine. *Syn.*—Aqua Chlorig. An aqueous solution of chlorine gas containing about 0.5 per cent. w/v of chlorine.

Liquor Sodæ Chlorinatæ, B.P.C.—(Liq. Sod. Chlorinat.)—Solution of Chlorinated Soda. It contains from 2.5 to 3.0 per cent. w/v of available chlorine. Dose:—0.6 to 1.2 millilitres (10 to 20 minims).

This solution was included in the British Pharmacopæia, 1914.

Liquor Sodæ Chlorinatæ Chirurgicæ, B.P.—(Liq. Sod. Chlorinat. Chn.)—Surgical Solution of Chlorinated Soda. *Syn.*—Dakin's Solution. It is prepared with chlorinated lime, sodium carbonate, boric acid and distilled water, and contains not less than 0.5 per cent. and not more than 0.55 per cent. w/v of available chlorine. It should be stored in well-closed containers, in a cool place, and protected from light. When stored it is liable to diminution in strength.

A similar solution was included in the British Pharmaceutical Codex, 1923, under the name of Liquor Sodæ Chlorinatæ cum Acido Borico.

Liquor Sodæ Chlorinatæ cum Sodii Bicarbonate, B.P.C.—(Liq. Sod. Chlorinat. c. Sod. Bicarb.)—Solution of Chlorinated Soda with Sodium Bicarbonate. *Syn.*—Daufresne's solution. It contains from 0.42 to 0.48 per cent. w/v of available chlorine.

CALX SULPHURATA

(Calx Sulphur.)

Sulphurated Lime*Synonym*—Calcium Sulphide.

Sulphurated lime is a mixture containing calcium sulphide ($\text{CaS} = 72.14$) and calcium sulphate, prepared by mixing calcium sulphate, 70 parts, and charcoal, 10 parts, packing the mixture lightly into a crucible, covering loosely, and heating to bright redness until the contents have lost their black colour. The product, after cooling, is powdered and at once transferred to well-closed containers. It occurs as a greyish-white, amorphous powder, with an odour of hydrogen sulphide, a disagreeable, alkaline taste and an alkaline reaction. It should be **stored** in well-closed containers.

Sparingly **soluble** in water; more soluble in boiling water, with decomposition; readily dissolved by solutions of ammonium salts; insoluble in alcohol.

Standard.—Sulphurated lime contains not less than 50 per cent. of CaS .

Assay.—Mix about 1 gramme, accurately weighed, with 10 millilitres of water in a 100 millilitre graduated flask, add 25 millilitres of copper sulphate solution and 10 millilitres of dilute hydrochloric acid, and warm on a water-bath for fifteen minutes, shaking frequently. Cool, make up to volume and filter, rejecting the first 25 millilitres of the filtrate; to 25 millilitres of the filtrate add 1 gramme of potassium iodide and titrate with $\text{N}/10$ sodium thiosulphate, using starch mucilage as indicator. Repeat the experiment, omitting the sulphurated lime, and calculate the result from the difference between the two titrations; each millilitre of $\text{N}/10$ sodium thiosulphate is equivalent to 0.007214 gramme of CaS .

Action and Uses.—Sulphurated lime is used to arrest and prevent suppuration, especially in the treatment of boils, carbuncles and pustular acne. It is **administered** in tablets, capsules and pills, which should be well varnished (not silvered) and kept in a bottle. A solution of calcium polysulphides (Liquor Calcis Sulphuratæ, Vlemminckx's solution) is used for application to the skin, either as a pigment or diluted (1 ounce to 5 gallons of water) for the bath, in the treatment of scabies and similar conditions. The name "lime-sulphur" is applied to a solution of calcium polysulphides which is used as a fungicide in horticulture. A dilution of 1 in 30 is used as a spray for fruit trees during the summer, and in winter a 1 in 60 dilution is similarly employed.

Dose.—0.016 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

Preparation

Liquor Calcis Sulphuratæ, B.P.C.—(Liq. Calc. Sulphurat) —Solution of Sulphurated Lime. *Syn.*—Lotio Calcis Sulphuratæ; Vlemminckx's Solution. An aqueous solution containing calcium polysulphides equivalent to from 4 to 5 per cent. w/v of sulphur.

CAMBOGIA

(Cambog.)

Gamboge

Gamboge consists of the gum-resin obtained from *Garcinia Hanburyi* Hook. f. (Fam. Guttiferae), a tree growing in Siam, Cambodia and the Southern part of Cochin China.

The gum-resin occurs in solid or hollow rolls or sticks (pipe gamboge), 2.5 to 5 centimetres in diameter and 10 to 20 centimetres long, exhibiting longitudinal striations derived from the inner surface of the bamboo in which the drug has been dried; lump or cake gamboge consists of pipe gamboge bent and pressed, while soft, into a cake. The fractured surface is smooth, with a dull gloss and a uniform brownish-orange colour. It has no odour, but an acrid taste. Gamboge forms with water a yellow emulsion which, on the addition of ammonia, becomes almost clear and of a deep orange-red colour. The drug is almost completely dissolved by treatment with alcohol and water successively. A thin splinter, mounted in oil and examined **microscopically**, shows a ground-mass of gum in which are scattered small granules of resin, an occasional crystal of calcium oxalate and a few starch grains.

Gamboge **contains** from 70 to 80 per cent. of resin, from which α , β and γ garcinolic acids have been isolated, and from 15 to 25 per cent. of a gum analogous to acacia and containing an oxydase.

Standard.—Gamboge yields to alcohol (90 per cent.) not less than 70 per cent. of extractive. Ash, not more than 3 per cent.

Action and Uses.—Gamboge is a powerful hydragogue cathartic, causing in large doses much irritation and griping. It is employed in dropsical conditions and in cerebral congestion when it is desirable to lower blood pressure rapidly, but is rarely used alone on account of its drastic action. It is usually **administered** in pills.

Dose. 0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains).

CAMBOGIA INDICA.—Indian gamboge is obtained from *Garcinia Morella* Desr. It has an action similar to that of gamboge, and is used as an equivalent of gamboge in India and the Eastern Colonies. Saigon gamboge is occasionally imported as short, thick, cylindrical cakes wrapped in palm leaves.

CAMPBORA

(Camph.)

Camphor

Camphor is a crystalline ketonic substance obtained from the wood of *Cinnamomum Camphora* Nees and Eberm., a tree growing abundantly in Formosa, Japan and China, or it may be prepared synthetically.

In the extraction of natural camphor, the wood, in small pieces, is subjected to a process of steam distillation; the crude camphor thus obtained contains a varying quantity of oil of camphor and is purified by sublimation. Synthetic camphor may be obtained from the pinene of oil of turpentine by conversion into camphene and subsequent oxidation. Synthetic camphor is the optically inactive *dl*-form; natural camphor is dextrorotatory.

Camphor occurs as a colourless, transparent, crystalline solid. According to the manner of condensation, it is known as "beils" or "flowers of camphor"; "blocks" and "tablets" are obtained by compression of the powder or by sublimation. The specific gravity of camphor is about 0.995. It has a characteristic, aromatic odour and a pungent, aromatic taste followed by a sensation of coldness. It burns with a bright, smoky flame, volatilises at ordinary temperatures and sublimates when heated. It may readily be powdered by trituration with a few drops of alcohol (90 per cent.) or other volatile, organic solvent. Camphor should be **stored** in a well-closed container in a cool place.

Soluble in water (about 1 in 700), alcohol (90 per cent.) (1 in 1), chloroform (1 in 0.25), ether (about 1 in 0.6), oil of turpentine (1 in 1.5), olive oil (1 in 3) and in other fixed vegetable oils.

Standard, B.P.—Camphor has a melting-point of 174° to 177° . Residue on volatilisation, not more than 0.05 per cent. It complies also with a limit test for water.

Action and Uses.—When applied externally, camphor dilates the vessels of the skin and is used as a rubefacient and mild counter-irritant. Internally, camphor has much the same action as the volatile oils and is prescribed as a carminative in flatulence. It mildly excites the circulation, dilating the superficial vessels and slightly increasing the cardiac output. It also directly excites the cerebrum. It is a popular remedy for the relief of colds. For internal use, camphor is **administered** in the form of Spiritus Camphoræ, and in pills, sometimes combined with dry extract of hyoscyamus, and as essence of camphor (Rubini's essence; an alcoholic solution, 1 in $2\frac{1}{2}$) given on sugar or in milk.

Camphor is given hypodermically as Injectio Camphoræ or Injectio Camphoræ Ætherea as a restorative in collapse, especially in pneumonia and other acute fevers. Its value in these conditions is due to its stimulating effect on the cortex and also on the vasomotor and respiratory centres in the medulla. Solutions of camphor in oil for **injection** may be prepared by dissolving the camphor in olive or almond oil which has been sterilised by heating at 150° for one hour and allowed to cool. The final container is sterilised by heating at 100° for thirty minutes, or at 112° for fifteen minutes. Camphor is a common ingredient of stimulating and anodyne liniments, such as Linimentum Camphoræ or Linimentum Camphoræ Ammoniatum. Camphorated chalk is a popular dentifrice. Stimulating and emollient ointments of camphor for the treatment of chilblains and cracked skin contain about 1 part in 6 parts, with wax, almond oil and sometimes a small percentage of thymol. The liquid obtained by mixing equal weights of camphor

and chloral hydrate is used as an anodyne pigment, sometimes with the addition of cocaine, menthol, or thymol. Camphor is excreted in the urine in combination with glycuronic acid. Toxic doses of camphor cause epileptiform convulsions followed by paralysis. In cases of **poisoning**, an emetic should be administered, stimulants, such as digitalis and strychnine, used freely by injection, and warmth applied to the extremities.

Dose.—0·12 to 0·3 gramme (2 to 5 grains); 0·06 to 0·2 gramme (1 to 3 grains), by subcutaneous injection.

Preparations

Aqua Camphoræ, B.P.—(Aq. Camph.)—Camphor Water. Camphor, 1 in 1000, and alcohol (90 per cent.), 1 in 500, in distilled water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Aqua Camphoræ Concentrata, B.P.C.—(Aq. Camph. Conc.)—Concentrated Camphor Water. Camphor, 1 in 25. One part added to 39 parts of distilled water yields a preparation which is equivalent in strength to camphor water, but contains 1·5 per cent. v/v of alcohol (90 per cent.). Dose.—0·3 to 1 millilitre (5 to 15 minims).

Chloral Camphoratum, B.P.C.—(Chloral Camph.)—Camphorated Chloral. *Syn.*—Chloral cum Camphora. Equal weights of chloral hydrate and camphor.

Chloroformum Camphoratum, B.P.C.—(Chlorof. Camph.)—Camphorated Chloroform. *Syn.*—Chloroform of Camphor. Camphor, 2 parts by weight, dissolved in chloroform, 1 part by volume.

Creta cum Camphora, B.P.C.—(Cret. c. Camph.)—Camphorated Chalk. Camphor, 1 in 10, with calcium carbonate.

Injectio Camphoræ, B.P.C.—(Inj. Camph.)—Injection of Camphor. Camphor, 1 in 10, in olive oil. Dose.—0·5 to 2 millilitres (8 to 30 minims), by subcutaneous injection.

Injectio Camphoræ Æthereæ, B.P.C.—(Inj. Camph. Æther.)—Ethereal Injection of Camphor. *Syn.*—Curschmann's Solution. Camphor, 1 in 5, and ether, about 1 in 3, in olive oil. Dose.—0·25 to 1 millilitre (4 to 15 minims), by subcutaneous injection.

Linctus Camphoræ Compositus, B.P.C.—(Linct. Camph. Co.)—Compound Linctus of Camphor. Camphorated tincture of opium, 1 in 4, with emulsion of chloroform, syrup of wild cherry, oxymel of squill, solution of bordeaux B and concentrated infusion of senega. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Linimentum Camphoræ, B.P.—(Lin. Camph.)—Liniment of Camphor. *Syn.*—Camphorated Oil. A solution of camphor, 20 per cent. w/w, in olive oil (limits, 19 to 21). It should be stored in well-closed containers in a cool place.

Linimentum Camphoræ Ammoniatum, B.P.—(Lin. Camph. Ammon.)—Ammoniated Liniment of Camphor. *Syn.*—Linimentum Camphoræ Compositum; Compound Liniment of Camphor. Camphor, 12·5 per cent. w/v, and strong solution of ammonia, 25 per cent. v/v, in alcohol (90 per cent.) or industrial methylated spirit suitably diluted, perfumed with oil of lavender.

Linimentum Chloroformi, B.P.C.—(Lin. Chlorof.)—Liniment of Chloroform. Chloroform and liniment of camphor, equal parts.

This liniment was included in the British Pharmacopæia, 1914.

Phenol cum Camphora, B.P.C.—(Phenol c. Camph.)—Phenol with Camphor. *Syn.*—Phenol Camphor, Carbolic Camphor. Phenol, 25 per cent. w/w, with camphor.

Pigmentum Chloralis et Camphoræ Compositum, B.P.C.—(Fig. Chloral. et Camph. Co.)—Compound Chloral and Camphor Paint. Equal weights of chloral hydrate, camphor and phenol.

Spiritus Camphoræ, B.P.—(Sp. Camph.)—Spirit of Camphor. Camphor, 10 per cent. w/v, in alcohol (90 per cent.). Dose.—0.3 to 2 millilitres (5 to 30 minims).

Syrupus Camphoræ Compositus, B.P.C.—(Syr. Camph. Co.)—Compound Syrup of Camphor. Camphor, 0.04 per cent. w/v, vinegar of squill and vinegar of ipecacuanha, of each 6.25 per cent. v/v, with oil of anise, benzoic acid, glacial acetic acid, tincture of opium, sucrose, solution of burnt sugar and distilled water. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tinctura Opii Camphorata, B.P.—(Tinct. Opii Camph.)—Camphorated Tincture of Opium. *Syn.*—Tinctura Opii benzoica I.A.; Tinctura Camphoræ Composita; Compound Tincture of Camphor; Paregoric; Paregoric Elixir. Tincture of opium, 5 per cent. v/v, with benzoic acid, camphor, oil of anise and alcohol (60 per cent.). It contains 0.05 per cent. w/v of morphine, calculated as anhydrous morphine (limits, 0.045 to 0.055); 4 millilitres contains 0.002 gramme and 1 fluid drachm contains about $\frac{1}{16}$ grain of morphine. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Unguentum Camphoræ, B.P.C.—(Ung. Camph.)—Camphor Ointment. Camphor, 10 per cent., in white soft paraffin.

Unguentum Camphoræ Durum, B.P.C.—(Ung. Camph. Dur.)—Hard Camphor Ointment. *Syn.*—Camphor Ice. Camphor, 6 per cent., in hard and soft paraffins.

CAMPHORÆ MONOBROMIDUM

(Camph. Monobrom.)

Camphor Monobromide

Synonyms Monobromated Camphor; Monobrom-Camphor.

Camphor monobromide is 3-bromocamphor and may be prepared by the action of bromine on camphor. It occurs in colourless, prismatic needles or scales, with a weak, but persistent, camphoraceous odour and taste. It boils at about 274°, volatilising completely with partial decomposition. Camphor monobromide evaporates slowly with the vapour of boiling water. It is permanent in air. It dissolves without decomposition in cold sulphuric acid and is precipitated on pouring the solution into water. Sodium amalgam reduces it to camphor. When heated with silver nitrate and nitric acid it is decomposed with production of silver bromide.

Insoluble in water; readily soluble in alcohol (1 in 12), ether (1 in 2), chloroform (10 in 7) and olive oil (1 in 8); sparingly soluble in glycerin.

Standard.—Camphor monobromide melts between 74° and 76°. Ash, not more than 0.05 per cent. 0.5 gramme shaken with 10 millilitres of water yields a filtrate which is neutral to litmus, and produces no appreciable opalescence on the addition of silver nitrate solution (limit of soluble bromide).

Action and Uses.—Camphor monobromide is used as a sedative and hypnotic, especially in chorea, hysteria and delirium tremens. Its use in large doses requires caution, since it may cause epileptiform convulsions. Its disadvantages are its unpleasant taste and smell and its irritant effect on the stomach. It may be **administered** in capsules or pills, or dissolved in oil and emulsified. Solutions in oil for **injection** may be prepared by dissolving the camphor monobromide in olive or almond oil which has been sterilised by heating at 150° for one hour and allowed to cool. The final container is sterilised by heating at 100° for thirty minutes.

Dose.—0.12 to 0.5 gramme (2 to 8 grains).

CANELLA

(Canell.)

Canella

Synonyms—Canella Bark; Canellæ Cortex; Wild Cinnamon Bark.

Canella consists of the bark from the trunk and branches of *Canella alba* Murray (Fam. Canellaceæ), a small tree indigenous to the West Indian Islands and to Florida. A thick, outer layer of ash-grey cork is first removed from the bark by gentle beating; this also loosens the remainder of the bark which is then stripped off and dried.

The bark occurs in simple quills or channelled pieces of variable size, but commonly 6 to 25 millimetres wide, 5 to 20 centimetres long and up to 3 millimetres thick; the outer surface is pale buff in colour, hard, wrinkled and marked with whitish spots; the internal surface is paler and finely striated longitudinally; the fracture is short and granular. The smoothed transverse surface exhibits a narrow, irregular, semi-translucent, yellowish-brown phelloderm, a paler cortex containing yellow oil cells and a secondary phloem with yellowish-white medullary rays arranged in somewhat triangular groups. The odour is aromatic and cinnamon-like, and the taste somewhat bitter and pungent.

The diagnostic **microscopical** characters are the phelloderm, which consists of stone cells strongly thickened on the radial and inner walls; numerous oil cells in the cortex and phloem; the simple or 2- to 3-compound starch grains, individual grains being up to 20 microns (usually about 5 to 10 microns) in diameter; the cluster-crystals of calcium oxalate in the medullary rays and scattered through the cortex; the occasional pericyclic fibres and the absence of bast fibres.

Canella **contains** volatile oil, which is present to the extent of about 1 per cent. and contains eugenol, cineol and terpenes. The bark also contains a bitter principle which has not been isolated; tannin is absent.

Standard.—Canella contains not more than 2 per cent. of foreign organic matter. Acid-insoluble ash, not more than 2 per cent.

Canella, in powder (Pulvis Canellæ : Pulv. Canell.), contains the constituents and possesses the diagnostic microscopical characters of Canella, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Canella is an aromatic bitter. A mixture of the powdered bark with aloes is sold under the name "Hiera Picra" (see Pulvis Aloes et Canellæ) and is used as an emmenagogue.

Preparation

Pulvis Aloes et Canellæ, B.P.C.—(Pulv. Aloes et Canell.)—Aloes and Canella Powder. *Syn.*—Hiera Picra. Aloes, 4 parts, and canella, 1 part. Dose. 0·2 to 0·6 grammes (3 to 10 grains).

CANNABIS

(Cannab.)

Cannabis

Synonyms—Cannabis Indica; Indian Hemp; Ganjah; Guaza.

Cannabis consists of the dried flowering and fruiting tops of the pistillate plant of *Cannabis sativa* Linn. (Fam. Cannabinaceæ), an annual diœcious herb indigenous to Central Asia and the Northern and Western Himalayas, and cultivated mainly in tropical districts of India, Africa and North America.

Cannabis occurs in flattened, dull green masses which remain more or less compacted together by the adhesive resinous secretion. The tops vary in length from about 3 to 30 centimetres, the smaller tops being preferred; they consist of the upper part of the stem with ascending branches, which are longitudinally furrowed and bear numerous covering and glandular trichomes. The leaves are alternate and consist of simple or palmately compound bracts, each having two linear stipules and bearing in its axil two bracteoles, each of which subtends a single pistillate flower or a more or less developed fruit occasionally containing an oily seed. The taste is very slight and the odour somewhat heavy and narcotic.

The diagnostic **microscopical** characters are the conical, curved, unicellular cystolith-trichomes with enlarged bases; the similar but more slender trichomes without cystoliths; the numerous, usually 8-celled, rosette-shaped, glandular trichomes with either unicellular or multiseriate pedicels; the bracteoles with very numerous small cluster-crystals of calcium oxalate; the red stigmas with long cylindrical papillæ; laticiferous tubes with brown contents; occasional, more or less lignified, phloem fibres from the stem, and brown, thick-walled, pitted cells from the palisade layer of the pericarp.

Cannabis **contains** a soft, brown resin (cannabinone), the chief constituent of which is cannabinal, $C_{21}H_{36}O_2$, a viscid, reddish oil, possessing a powerful narcotic action, but resinifying and becoming less active on exposure to air; choline, and traces of volatile oil, fat and

wax are also present. Cannabis yields to alcohol (90 per cent) from 10 to 22 per cent. of extractive. The ash is about 15 per cent. The following test has been used for the identification of cannabis:—Shake 0·1 gramme in powder with 5 millilitres of light petroleum for three minutes and filter; to 1 millilitre of the filtrate add 2 millilitres of a 15 per cent. w/v solution of hydrogen chloride in dehydrated alcohol; at the junction of the two liquids a red colouration appears, and, after shaking, the upper layer becomes colourless and the lower layer acquires an orange-pink colouration which disappears on the addition of one millilitre of water.

Varieties.—Tinctures of cannabis, prepared from African, American, German and Indian varieties of the drug, when examined by oral administration to cats, appear to possess about the same degree of activity, and this activity is not destroyed by long storage of the drug in a dry condition.

Standard.—Cannabis contains not more than 10 per cent. of fruits, large foliage leaves, and stems over 3 millimetres in diameter, and not more than 2 per cent. of other foreign organic matter. Acid-insoluble ash, not more than 5 per cent. When a mixture of 10 grammes of finely powdered cannabis and 100 millilitres of alcohol (90 per cent.) is shaken occasionally during twenty-four hours and then filtered, 20 millilitres of the filtrate, evaporated in a flat-bottomed dish, yields a residue weighing, when dried at 100°, not less than 0·20 gramme. Cannabis indicæ herba I.A. consists of the tops, in flower and in fruit, of the female plant cultivated in the East Indies.

Cannabis, in powder (Pulvis Cannabis: Pulv. Cannab.), contains the constituents and possesses the diagnostic microscopical characters of Cannabis, and complies with the limits for acid-insoluble ash and residue on extraction with alcohol (90 per cent.) of the unground drug.

Action and Uses.—Cannabis acts chiefly on the central nervous system. It first produces excitement with hallucinations, a feeling of happiness and indifference to surroundings, this stage being followed by deep sleep. The hallucinations include inability to estimate time and space. In the East the hemp is smoked and almost immediately produces symptoms of pleasurable excitement, followed by depression and lethargy. Cannabis is used as an anodyne sedative or hypnotic in mania, spasmodic coughs, phthisis, asthma and dysmenorrhœa. It has been used in the treatment of chorea and paralysis agitans. It does not produce constipation or loss of appetite. Cannabis is usually **administered** as the extract in pills, or as tincture. In cases of **poisoning** the stomach should be evacuated and the usual methods adopted to prevent collapse and respiratory failure.

CANNABINÆ TANNAS.—Cannabine tannate is a brownish powder which may be obtained from an aqueous extract of cannabis by precipitation with tannic acid. It has been used as a hypnotic in nervous insomnia, in dysmenorrhœa and in menorrhagia. Dose.—0·25 to 0·5 gramme (4 to 8 grains).

CANNABINONUM.—Cannabinone, the brown resin obtained from cannabis, has been used as a hypnotic in hysteria and insomnia. Dose.—0·016 to 0·06 gramme ($\frac{1}{4}$ to 1 grain).

Preparations

Extractum Cannabis, B.P.C.—(Ext. Cannab.)—Extract of Cannabis. A soft extract. Dose.—0.016 to 0.06 grammes ($\frac{1}{4}$ to 1 grain).

This extract, prepared from Indian hemp, was included in the British Pharmacopœia, 1914, under the name of Extractum Cannabis Indicæ.

Extractum Cannabis indicæ I.A. is prepared from cannabis cultivated in the East Indies.

Tinctura Cannabis, B.P.C.—(Tinct. Cannab.)—Tincture of Cannabis. Extract of Cannabis, 1 in 20. Dose.—0.3 to 1 millilitre (5 to 15 minims).

This tincture, prepared from Indian Hemp, was included in the British Pharmacopœia, 1914, under the name of Tinctura Cannabis Indicæ.

Tinctura Cannabis indicæ I.A. is prepared with alcohol (90 per cent.) from 10 per cent. of cannabis cultivated in the East Indies.

CANTHARIDINUM

(Cantharidin.)

Cantharidin

Cantharidin is the lactone of cantharidic acid and is obtained from cantharides or mylabris. The insects are crushed and the powder digested for two days in a mixture of sulphuric acid and ethyl acetate; the product is mixed with barium carbonate and extracted with light petroleum. The latter is then removed and the residue set aside for the cantharidin to crystallise. The crystals are warmed with light petroleum to remove fat, and the cantharidin recrystallised from alcohol. It occurs in colourless, odourless, glistening crystals which sublime at about 120° . It dissolves in solutions of alkali hydroxides with formation of cantharidates and is reprecipitated on the addition of acid.

Very slightly **soluble** in water; soluble in alcohol (90 per cent.) (about 1 in 1100), ether (1 in 700), chloroform (1 in 55), acetone (1 in 40), ethyl acetate (1 in 150), and fixed oils.

Standard, B.P.—Cantharidin has a melting point of 216° to 218° . Ash, not more than 0.1 per cent. It complies also with a *liovt* test for readily carbonisable substances.

Action and Uses.—Cantharidin, which is very irritating to the skin and mucous membrane, should be used with great care. After absorption it produces marked vasoconstriction and, during excretion, it gives rise to irritation of the kidneys and urinary tract. It may be **administered** in the form of Liquor Cantharidini but is rarely used internally. It possesses aphrodisiac properties. It is, however, chiefly used externally as a blistering agent and counter-irritant, Collodium Vesicans, Emplastrum Cantharidini and Unguentum Cantharidini being suitable preparations for this purpose. Liquor Epispasticus is painted on the skin as a vesicant to relieve inflammation in deep-seated parts, as in pleurisy, pericarditis and mastoid inflammation, and for

neuralgia. Emplastrum Calefaciens is a milder preparation which may be used where a rubefacient rather than a vesicant is indicated.

Cantharidin is also used in hair lotions, owing to its supposed stimulating action on the growth of the hair. In acid hair lotions, Acetum Cantharidini is a suitable preparation for inclusion, while Liquor Cantharidini is preferable for addition to ammoniacal lotions. Cantharidin in the form of ointment is also used for application to the scalp. In cases of **poisoning** by cantharidin, emetics should be given, and the stomach pump applied, followed by mucilaginous drinks with ice; oils and fats should be avoided.

Preparations

Acetum Cantharidini, B.P.C.—(Acet. Cantharidin.)—Vinegar of Cantharidin. Cantharidin, 1 in 2000, with glacial acetic acid and acetic acid.

This vinegar was included in the British Pharmacopœia, 1914.

Collodium Vesicans, B.P.C.—(Collod. Vesic.)—Blistering Collodion. Blistering liquid containing pyroxvlin, 1 in 40, coloured with cochineal.

This collodion was included in the British Pharmacopœia, 1914.

Emplastrum Calefaciens, B.P.C.—(Emp. Calefac.)—Warming Plaster. Cantharidin, 1 in 5000, in olive oil and plaster of colophony, prepared with chloroform.

This plaster was included in the British Pharmacopœia, 1914.

Emplastrum Cantharidini, B.P.—(Emp. Cantharidin.)—Plaster of Cantharidin. *Syn.*—Cantharidin Plaster, Blistering Plaster. Cantharidin, 0.2 per cent., with castor oil, yellow beeswax and wool fat, prepared with acetone.

Liquor Cantharidini, B.P.C.—(Liq. Cantharidin.)—Solution of Cantharidin. *Syn.*—Tinctura Cantharidini; Tincture of Cantharidin. Cantharidin, 1 in 10,000, in chloroform and alcohol (90 per cent.). Dose.—0.12 to 0.3 millilitre (2 to 5 minims).

This solution was included in the British Pharmacopœia, 1914, under the name of Tinctura Cantharidini.

Tinctura Cantharidis I.A. is prepared with alcohol (70 per cent.) and contains 0.06 per cent. of cantharidin.

Liquor Epispasticus, B.P.—(Liq. Epispast.)—Blistering Liquid. Cantharidin, 0.4 per cent. w/v, with castor oil and colophony, in acetone.

Lotio Cantharidini, B.P.C.—(Lot. Cantharidin.)—Cantharidin Lotion. *Syn.*—Lotio Crinalis Stimulans. Cantharidin, 1 in 5000, with acetone and castor oil, in alcohol (90 per cent.).

Unguentum Cantharidini, B.P.C.—(Ung. Cantharidin.)—Cantharidin Ointment. Cantharidin, 0.033 per cent., with chloroform, in benzoinated lard.

This ointment was included in the British Pharmacopœia, 1914.

CANTHARIS

(Canthar.)

Cantharides

Synonyms—Spanish Fly; Blistering Beetle.

Cantharides consists of the dried beetle, *Cantharis vesicatoria*

Latr. (Order Coleoptera; Fam. Meloidæ), which is widely distributed over Southern Europe, living gregariously in olive trees, ash trees, etc. The beetles are collected before sunrise, when unable to use their wings, by shaking them from the trees on to cloths spread underneath; they are then killed by means of ammonia, vinegar, sulphur dioxide or by stove heat. The drug should be **stored** in containers which prevent access of moisture.

The beetles are from 12 to 20 millimetres long and 3 to 6 millimetres broad, smooth and of a shining green or bronze-green colour. The head is trapezoid, and the eyes small and near the antennæ. The posterior margin of the vertex of the head shows a median groove; the prothorax is hexagonal; the elytra are wider than the prothorax, almost glabrous, and meet in a straight line down the centre; the hind wings are brown and membranous. The antennæ are filiform, with eleven joints; the second joint is very small and sub-globular; the third joint is a little longer than the fourth, but is never as much as twice as long. The tarsi of the fore and middle legs have five joints, while those of the hind legs have four joints; none of the joints is bilobed. There are two pairs of smooth, terminal claws on each foot, the external ones being strong and robust while the internal ones are delicate.

The diagnostic **microscopical** characters of cantharides are the abundance of groups of striated muscle fibres; the portions of glabrous elytra showing in surface view a delicate polygonal net work, beneath which are scattered, brown, circular areas, each surrounded by a double concentric ring; fragments of the legs, antennæ and other limbs and of the exoskeleton bearing hairs of various shapes and sizes. The dry powder viewed microscopically by reflected light exhibits bright green particles from the elytra.

Cantharides **contains** cantharidin, a crystalline lactone, of which commercial specimens yield from 0.4 to 0.8 per cent. It exists in the beetles chiefly in the free state, but a varying proportion is combined in the form of salts. The beetles also contain about 12 per cent. of fat and yield about 8 per cent. of ash.

Standard.—Cantharides contains not more than 2 per cent. of foreign organic matter and not more than 10 per cent. of moisture.

Cantharides, in powder (*Pulvis Cantharidis* : *Pulv. Canthar.*), contains the constituents and possesses the diagnostic microscopical characters of *Cantharis*, and complies with the limit for moisture of the unground drug. It is adjusted, if necessary, by the addition of powder of higher or lower cantharidin content to contain not less than 0.6 per cent. of cantharidin. *Pulvis Cantharidis* I.A. contains not less than 0.6 per cent. of cantharidin.

Assay.—To 15 grammes, in coarse powder, in a stoppered bottle, add 150 millilitres of chloroform and 1 millilitre of hydrochloric acid, and shake frequently during twenty-four hours. Filter and evaporate 100 millilitres of the filtrate (equivalent to 10 grammes of the drug) in a porcelain dish, avoiding unnecessary heat. Add 10 millilitres of light

petroleum, stir with a glass rod, allow to settle, and pour through a plug of cotton wool. Continue washing with 5 millilitre portions of light petroleum until the washings are colourless, and the fat is removed. Transfer all particles adhering to the cotton wool back into the dish by means of a few millilitres of chloroform, evaporate the chloroform, add 5 millilitres of N/1 sodium hydroxide and rub into a smooth cream, ensuring that all parts of the dish are covered. Now add 10 millilitres of a 5 per cent. solution of potassium permanganate and warm on the steam-bath for ten minutes, stirring frequently. Allow to cool, and transfer the contents of the dish to a separator; add 4 millilitres of 40 per cent. sulphuric acid to the dish, stir well, and after two minutes transfer to the separator; add 30 millilitres of chloroform to the dish, stir thoroughly and transfer to the separator, and finally wash the dish with a few millilitres of water. Add to the contents of the separator 5 grammes of ferrous sulphate in small crystals and shake vigorously for five minutes. Separate the chloroform and shake the acid liquid with two successive portions of 30 millilitres of chloroform. Evaporate the chloroform at a temperature not exceeding 65°, dry and weigh the residue.

Action and Uses. Cantharides and its preparations, when applied to the skin, produce redness followed by vesicles, which coalesce to form a blister. Externally, preparations of cantharides are used as rubefacients, counter-irritants, and vesicants. They should not be applied over very large surfaces on account of the risk of absorption, especially when there is renal disease. Cantharides is now largely replaced by cantharidin, thereby ensuring preparations of a more uniform strength. In cases of **poisoning**, the same treatment should be adopted as in cases of poisoning by Cantharidinum.

Preparations

Acetum Cantharidis, B.P.C.—(Acet. Canthar.)—Vinegar of Cantharides. Cantharides, 1 in 10, extracted with a mixture of glacial acetic acid and water.

Emplastrum Lyttæ, B.P.C.—(Emp. Lyttæ)—Plaster of Cantharides. Cantharides, about 1 in 3, with yellow beeswax, lard, colophony and plaster of soap.

CAOUTCHOUC

(Caoutchouc)

Rubber

Rubber consists of the prepared latex of *Hevea brasiliensis* Müll. Arg. (Fam. Euphorbiaceæ), and other species of *Hevea* indigenous to Brazil and cultivated in the Malay Archipelago, Ceylon and elsewhere. The latex is obtained by making a series of incisions in the bark of the tree ("tapping") and collecting the comparatively limpid fluid in suitable vessels placed beneath them. In Brazil, "Pará rubber" is prepared by coagulating the latex in successive layers on a stick or paddle held in the smoke of burning palm nuts. The latex obtained from cultivated

trees is usually preserved by the addition of ammonia, until a sufficient quantity has been collected for transfer to a central factory where it is coagulated with dilute acid or alum solution, after which the liquid portion is pressed out and the rubber dried ("plantation rubber").

Pará rubber occurs in flattish masses of various sizes, brownish-black externally, paler internally, exhibiting, in section, a series of thin concentric layers, separated by darker lines. Plantation rubber occurs in the form of thin sheets (sheet or crêpe rubber), discs (biscuit rubber), or masses (block rubber), and is usually of a lighter colour than Pará rubber. Rubber has a characteristic odour and is almost tasteless. It possesses considerable elasticity, which is gradually lost on prolonged storage. When heated to 125°, it melts and remains soft and adhesive after cooling. When treated with benzol, carbon disulphide, chloroform, mineral naphtha, or oil of turpentine, rubber swells, becoming soft and gelatinous.

Rubber **contains** from 40 to 60 per cent. of the hydrocarbon caoutchouc, 30 to 50 per cent. of a gelatinous substance, and 1 to 4 per cent. of various other constituents, such as resin, fat, colouring matters and mineral substances. Pure caoutchouc is a white, amorphous substance of the empirical formula, C_5H_8 , and appears to be an isomeride of gutta. When subjected to dry distillation, it yields "oil of caoutchouc"—a mixture of hydrocarbons, including isoprene, dipentene, etc.

Substitutes.—Assam rubber from *Ficus elastica* Roxb. (Fam. Moraceæ) occurs as dark red masses. Mangabeira rubber from *Hancornia speciosa* Gomez (Fam. Apocynaceæ) is in the form of large, pinkish-white pieces. Central American rubber, from *Castilloa elastica* Cerv. and other species of *Castilloa* (Fam. Moraceæ), is in black slabs composed of a mass of wavy sheets. West African rubber is obtained from *Funtumia elastica* Stapf and *Landolphia florida* Benth. (Fam. Apocynaceæ). Mozambique rubber from *Landolphia Kirkii* Dyer (Fam. Apocynaceæ) occurs in balls or sausage-shaped masses. Ceara rubber from *Mimot Glazouvi* Mull. Arg. (Fam. Euphorbiaceæ) consists of strings rolled into balls.

Uses.—Rubber is a constituent of the bases of self-adhesive plasters, with which medicaments, such as zinc oxide, belladonna, capsicum, etc., are incorporated. Liquor Caoutchouc is a solution of 1 part of rubber in 20 parts of equal volumes of benzene and carbon disulphide; mixed with powdered mustard seed (freed from fixed oil), it is used in the preparation of Charta Sinapis. Solutions of gutta percha are much to be preferred to those of rubber for the application of such medicaments as chrysarobin and resorcinol to the skin when close and prolonged contact is required. The rubber film is moist and sticky, that of gutta percha is dry and hard.

Preparations

Emplastrum Adhesivum, B.P.C.—(Emp. Adhesiv.)—Rubber Adhesive Plaster.

This plaster is spread with a rubber adhesive compound containing not more than 25 per cent. of fillers.

Gamentum Elasticum Adhesivum, B.P.C.—(Ligament. Elastic. Adhesiv.)

Elastic Adhesive Bandage. This bandage is spread with a rubber adhesive compound containing not less than 20 per cent. of zinc oxide.

CAPSICUM

(Capsic.)

Capsicum*Synonyms.*—Capsici Fructus; Capsicum Fruit.

Capsicum consists of the dried, ripe fruits of *Capsicum minimum* Roxb. (Fam. Solanaceæ), a small, erect shrub indigenous to tropical America and cultivated in Africa (Sierra Leone and Zanzibar), South America and other tropical countries.

The fruits are of a dull orange-red colour and oblong-conical shape; they are obtuse at the apex, two-celled, and vary from about 12 to 25 millimetres in length and up to about 7 millimetres in diameter at the widest part. Occasionally the fruits are attached to a 5-toothed, inferior calyx and a straight, slender pedicel, the length of pedicel and calyx being about 2 to 3 centimetres. The pericarp is somewhat shrivelled, glabrous, translucent and leathery; it encloses about 10 to 20 flat, reniform seeds; the seeds are about 3 to 4 millimetres in length and occur either loose or attached to a reddish dissepiment. Capsicum has a characteristic, but not powerful, odour and an extremely pungent taste. The pungency is not destroyed by boiling with 2 per cent. alcoholic potash solution (distinction from ginger).

The diagnostic **microscopical** characters are the outer epidermal cells of the pericarp often arranged in rows of five to seven, the walls being straight, moderately and uniformly thickened, and exhibiting a uniformly striated cuticle; the droplets of red oil in many of the parenchymatous cells of the pericarp; the characteristic inner epidermis of the pericarp showing groups of sclerenchymatous cells separated by thin-walled parenchyma; the epidermis of the seed, composed of very large sinuous cells with thin outer walls, but strongly thickened and pitted radial and inner walls.

Capsicum **contains** the crystalline, colourless, pungent principle, capsaicin, $C_{18}H_{27}O_3N$, of which about 0.14 per cent. is present. It melts at 64.5° and is volatile at higher temperatures, the vapour being extremely irritating; it can be extracted from acid solution by means of ether. The fruit also contains a fatty oil, red colouring matter and traces of a liquid alkaloid, none of which is pungent. It yields to alcohol (60 per cent.) from 20 to 25 per cent. of extractive and to acetone about 10 per cent. The seeds may contain traces of starch.

Varieties.—The fruits of *Capsicum minimum* are known commercially as African chillies. Sierra Leone capsicum is regarded as the most pungent; the pod is somewhat slender and of a bright colour. Nyasaland capsicum closely resembles the Sierra Leone, but is brighter in colour and more free from stalk. Zanzibar capsicum is usually duller in colour, it usually contains more stalks and the pods are somewhat shorter and broader. Madagascar capsicum is almost free from stalks, yellow to orange-red in colour, and rather broader.

Substitutes and Adulterants.—Japanese chillies possess about one quarter of the pungency of the African varieties, but are valued for their very bright colour. They are probably derived from *C. frutescens* Linn. and are distinguished from the official drug by their very bright reddish colour and freedom from stalk; the cells

of the epidermis of the pericarp have a smooth cuticle, strongly thickened walls and radiate lumen; the cells of the single layered hypoderma have somewhat thick, pitted, cuticularised walls. Bombay chillies are obtained from *C. annuum* Linn.; the fruits vary in size and shape, are very broadly ovate and larger but less pungent than the official drug. The stalk is usually bent, the calyx larger, the pericarp leathery, and the dissepiment does not usually extend throughout the entire length of the fruit. The epidermal cells are larger and polygonal in outline and have numerous pits; the hypoderma consists of several layers of cuticularised collenchymatous cells. Natal chillies are much larger, averaging about 8 centimetres in length. The pericarp is transparent and red. Paprika is extensively grown and used in Hungary and is derived from mild races of *C. annuum*; the fruits are large and more or less tetragonal and have a conspicuous green calyx. Bird pepper is derived from *C. annuum* var. *groszum*, grown in Spain and other milder races of *C. annuum* grown in Hungary, and is free from pungency.

Standard, B.P.—Capsicum contains not more than 3 per cent. of calices and pedicels, and not more than 1 per cent. of stalks and other foreign organic matter. Ash, not more than 7 per cent.

Capsicum, in powder (*Pulvis Capsici*: *Pulv. Capsic.*), contains the constituents and possesses the diagnostic microscopical characters of Capsicum, and complies with the limit for ash of the unground drug.

Action and Uses. Capsicum is given **internally** as a powerful stimulant and carminative to the alimentary canal, especially in flatulent dyspepsia. For internal use, tincture of capsicum is administered with bitters and tonics; it is sometimes added to tannin or rose gargles for pharyngitis and relaxed sore throat. Capsicum is sometimes used with other drugs such as *nux vomica* or cinchona in the treatment of alcoholism. When its pungent taste is objectionable, powdered capsicum may be dispensed in pills with compound rhubarb pill or reduced iron. **Externally**, capsicum is an irritant, producing warmth, redness and vesication. It is used for rheumatism, lumbago, neuralgia and generally where counter-irritation is indicated. The tincture is too weak for external use; for this purpose the strong tincture (*Tinctura Capsici Fortior*) and liniment are preferred. These are used by painting on the skin, or by sprinkling on lint or cellulose wadding and applying to the part.

Capsicum ointments, simple or compound, are used for application to painful joints in synovitis and rheumatoid arthritis. Capsicum wool and tissue have been found of service as applications to rheumatic joints and to the chest; in bronchial inflammation they have a mild rubeficient action on the skin. Capsicum plasters are prepared in several forms, such as very small plasters on thin felt for application to the gums as a counter-irritant, capsicum plasters with a soap basis, prepared with oleoresin of capsicum, and the same, self-adhesive, in rubber combination for application to the back, chest, or wherever counter-irritation may be required.

Dose.—0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains).

Preparations

Emplastrum Capsici, B.P.C.—(*Emp. Capsic.*)—Plaster of Capsicum. Oleoresin of capsicum, 1 in 50, with plaster of colophony.

Emplastrum Capsici Elasticum, B.P.C.—(Emp. Capsic. Elast.)—Rubber Plaster of Capsicum. Oleoresin of capsicum, 1 in 50, with rubber adhesive plaster.

Gossypium Capsici, B.P.C.—(Gossyp. Capsic.)—Capsicum Wool. This wool contains the equivalent of about 20 per cent. of capsicum.

Linimentum Capsici, B.P.C.—(Lin. Capsic.)—Liniment of Capsicum. Stronger tincture of capsicum, about 1 in 3, with oleic acid, oil of lavender and alcohol (90 per cent.).

Oleoresina Capsici, B.P.C.—(Oleores. Capsic.)—Oleoresin of Capsicum. *Syn.*—Capsicin; Extract of Capsicum. The alcohol-soluble portion of the ether extract of capsicum. It is approximately four times the strength of the oleoresin of the British Pharmaceutical Codex, 1923. Dose.—0.006 to 0.002 gramme ($\frac{1}{160}$ to $\frac{1}{80}$ grain).

Tela Carbasi et Gossypii Capsici, B.P.C.—(Tel. Carbas. et Gossyp. Capsic.)—Capsicum Tissue. Capsicum tissue consists of capsicum wool enclosed in absorbent gauze.

Tinctura Capsici, B.P.—(Tinct. Capsic.)—Tincture of Capsicum. 1 in 20 prepared by maceration with alcohol (60 per cent.). Dose.—0.3 to 1 millilitre (5 to 15 minims)

Tinctura Capsici Fortior, B.P.C.—(Tinct. Capsic. Fort.)—Stronger Tincture of Capsicum. *Syn.*—Turnbull's Tincture of Capsicum. 1 in 3. Dose.—0.06 to 0.2 millilitre ($\frac{1}{16}$ to 3 minims)

Unguentum Capsici, B.P.—(Ung. Capsic.)—Ointment of Capsicum. *Syn.*—Capsicum Ointment. It contains active constituents approximately equivalent to 25 per cent. w/w of capsicum, extracted by digestion in a mixture of lard and hard and soft paraffins

Unguentum Capsici Compositum, B.P.C.—(Ung. Capsic. Co.)—Compound Capsicum Ointment. *Syn.*—Unguentum Oleoresinæ Capsici Compositum; Compound Capsicum Oleoresin Ointment; Chilliæ Paste. Oleoresin of capsicum, 2 per cent., with menthol, chloral hydrate and camphor, in yellow soft paraffin.

Unguentum Capsici Forte, B.P.C.—(Ung. Capsic. Fort.)—Strong Capsicum Ointment. *Syn.*—Unguentum Oleoresinæ Capsici; Capsicum Oleoresin Ointment. Oleoresin of capsicum, 4.5 per cent., with yellow beeswax and benzoated lard.

CARBO

(Carbo)

Charcoal

Synonyms Carbo Ligni; Medicinal Charcoal; Purified Charcoal.

Charcoal consists of the carbonaceous residue of wood charred by exposure to a red heat without access of air, the wood of the beech, oak, poplar, hazel, dogwood and willow usually being used for the purpose. Willow charcoal is most commonly used in this country. The yield of charcoal is from 17 to 18 per cent. when the wood is simply protected from the air with earth and sods, and from 22 to 23 per cent. when charred in iron cylinders. Charcoal is also prepared in a more active condition from other material, including coconut shells, by heating in a current of activating gases, in the presence of certain inorganic salts. The product is washed free from mineral matter and dried. It occurs

as a black, tasteless and odourless powder. It should be **stored** in well-closed containers.

Standard.—Charcoal leaves not more than 7 per cent. of ash. The filtrate, obtained by boiling 1·5 grammes with 15 millilitres of distilled water and 5 millilitres of potassium hydroxide solution for thirty seconds and filtering, is not coloured more than light brown. Moisture, not more than 15 per cent. Boil 5 grammes with a mixture of 5 millilitres of dilute hydrochloric acid and 20 millilitres of water; dilute with water to 100 millilitres, filter, and apply the following tests:—Mix 10 millilitres of filtrate with an equal volume of saturated aqueous solution of hydrogen sulphide, warm, and allow to stand for thirty minutes; not more than the faintest darkening occurs (limit of heavy metals). To 20 millilitres of filtrate add 5 millilitres of ammonium chloride solution, and solution of ammonia in excess, boil, and filter; no blue colour should be visible in the filtrate; make the filtrate slightly acid with hydrochloric acid and add several drops of potassium ferrocyanide solution; no immediate precipitate is produced (limit of copper and zinc). 2·5 millilitres of filtrate complies with the limit test for iron.

Action and Uses.—Charcoal has the power of adsorbing gases and of removing by adsorption many substances from aqueous solutions. It is used **internally**, alone or with kaolin, as an antiseptic and absorbent in flatulent dyspepsia, intestinal distension, diarrhoea and dysentery. Its action is partly mechanical, removing mucus and stimulating the movements of the stomach and intestine, and partly the result of the adsorption of toxins. Charcoal is also used to indicate the passage of intestinal contents. It is sometimes employed as a poultice.

The powder is usually **administered** in cachets, sometimes with sodium bicarbonate, bismuth carbonate and betanaphthol. Lozenges of charcoal and of charcoal with bismuth are prepared. Charcoal biscuits are a popular form of administration. On account of its high adsorptive power, it has been used largely in respirators as a defence against poison gas, and in pharmacy and the arts for decolourising solutions, but for technical purposes activated charcoal is now preferred.

Dose.—4 to 8 grammes (1 to 2 drachms).

CARBO ACTIVATUS

(Carbo Activat.)

Activated Charcoal

Synonym—Decolourising Carbon.

Activated charcoal may be prepared from vegetable matter, such as woodst, cellulose residues and coconut shells, by carbonisation, heating the charcoal to a high temperature, with or without the addition of inorganic salts, in a stream of activating gases, usually steam, and subsequent purification by washing with acids to remove mineral matter. It occurs in the form of a fine, black powder, the commercial

varieties varying widely in their characteristics, some being neutral, others acid or alkaline, depending upon the method of manufacture.

Different varieties are used for different purposes, since a charcoal produced to have the maximum power for adsorbing gases may not be the most efficient for decolourising liquids. Their action is explained by adsorption, and in this respect it is estimated that one cubic inch of a good sample offers a surface of over 20,000 square yards. The comparative activity of various samples may be determined by measuring the number of millilitres of a 0.25 per cent. caramel solution decolourised on shaking 0.1 gramme of activated charcoal with an excess of the caramel solution for one hour at 50°; a decolourisation of not less than 15 millilitres may be considered as a satisfactory test. Good samples yield not more than about 15 per cent. of moisture or 10 per cent. of ash. It should be **stored** in well-closed containers.

Uses.—Activated charcoal is used as a purifying agent in many chemical and pharmaceutical processes, and for the removal of colour from solutions. The precise method of using it depends to a certain extent on the nature of the substance and the reaction of the solution. It is also used for the adsorption of gases and special varieties are of value in removing residual gases in low pressure apparatus. When activated charcoal is used for internal administration it must comply with the requirements for Carbo.

CARBO ANIMALIS

(Carbo Animal.)

Animal Charcoal

Synonyms—Carbo Animalis Purificatus; Purified Animal Charcoal.

Animal charcoal is prepared by boiling crude animal charcoal with hydrochloric acid, washing thoroughly, drying and reheating. It occurs as an odourless, tasteless powder, and may yield as much as 10 per cent. of ash. Crude animal charcoal is the material prepared by heating bones with a limited access of air and consists chiefly of calcium phosphate and other inorganic constituents of bone, with about one-tenth its weight of carbon; it occurs in dull black, granular fragments, or as a dull black, odourless powder.

Uses.—Animal charcoal has been used to decolourise solutions before filtration, but activated charcoal is now preferred for this purpose.

CARBONEI DIOXIDUM

(Carbon. Diox.)

Carbon Dioxide

CO₂ 44.00

Carbon dioxide may be obtained from naturally occurring carbonates,

particularly the carbonates of calcium and magnesium, by treatment with an acid, but is more commonly obtained as a by-product of alcoholic fermentation in breweries. It is supplied condensed in metal cylinders. Carbon dioxide is a heavy, colourless, odourless gas which does not support combustion; it is about 1.5 times as heavy as air. The aqueous solution has weakly acidic properties and reddens blue litmus. The gas is readily absorbed by the hydroxides of the alkali and alkaline earth metals with formation of carbonates or bicarbonates; when passed into solution of calcium or barium hydroxide, a white precipitate of the corresponding carbonate is produced. Carbon dioxide can be liquefied by pressure at temperatures below 31° , at which temperature a pressure of 72 atmospheres is required.

Liquid carbon dioxide is a limpid, colourless liquid which is immiscible with water, but readily dissolves in alcohol, ether and volatile oils; at atmospheric pressure it boils at about -72° . Solid carbon dioxide, "dry ice" or "carbon dioxide snow" is prepared extensively and, owing to its low thermal conductivity, it is more stable than the liquid.

Soluble in water (about 1 in 1.3 at 25°).

Standard, B.P.—Carbon dioxide contains not less than 99 per cent. v/v of CO_2 . It complies with a test for the absence of carbon monoxide and with limit tests for acid and sulphur dioxide, and for phosphine, hydrogen sulphide and organic reducing substances.

Action and Uses.—Solutions of carbon dioxide, as in the effervescent salines, are used in medicine in order to mask the unpalatable nature of the saline aperients. The action of carbon dioxide on the stomach is to increase the blood flow. It is of value in chronic gastritis as a stimulant to the appetite and to promote the secretion of hydrochloric acid and enzymes. In cases of vomiting, carbon dioxide in solution such as a mixture of sodium bicarbonate and citric acid taken during effervescence, is often a useful measure. The aerated waters are efficient diuretics. Carbon dioxide is a powerful respiratory stimulant. In conjunction with oxygen it is a valuable therapeutic agent in cases of weak or suspended respiration, resulting from, for example, drowning, or coal-gas or morphine poisoning, or to stimulate respiration in newly born infants. It is, of course, necessary to use artificial respiration in the first place when the respiration has ceased. Oxygen with 5 to 10 per cent. of carbon dioxide is used frequently to increase the respiratory movements after a general anæsthetic before consciousness is regained, and it is employed in cases of prolonged unconsciousness from any cause. Post-operative chest complications, such as pneumonia or massive collapse, are less liable to occur if carbon dioxide is administered as a routine. Inhalation of carbon dioxide mixed with oxygen is also used to relieve whooping cough and spasmodic asthma.

The liquefied gas is used industrially for aerating waters, and for refrigerating and other purposes. **Carbon dioxide snow** is obtained by the sudden release of the liquid carbon dioxide from an inverted cylinder. It has a temperature of -80° . The snow is shaped to suit

the part which it is desired to treat by compressing it into suitable moulds. It has a destructive action on tissues and is used to destroy warts and naevi. It is applied with light pressure for from five to sixty seconds according to the condition it is desired to treat. A wheal is afterwards formed, followed by a vesicle, which requires to be treated like a blister. The application is practically painless and, as the pencil may be trimmed to a point, the treatment can be strictly localised. Before making a second application, when necessary, the inflammation resulting from the first should have been allowed to subside. Very little scar is formed when this method is followed.

CARBONEI DISULPHIDUM

(Carbon. Disulph.)

Carbon Disulphide

CS_2 . 76.12

Synonym—Carbon Bisulphide.

Carbon disulphide is formed by passing the vapour of sulphur over red-hot carbon, the product being condensed and subsequently purified. It occurs as a clear, colourless, highly refractive, limpid liquid, with a characteristic odour. It should not have a foetid odour. It is volatile and highly inflammable, burning with a blue flame to carbon dioxide and sulphur dioxide. Its flash-point is about -20° . Its ignition-point is very low, being under 200° . The vapour mixed with air is explosive in contact with flame. Its refractive index at 20° is about 1.628. It decomposes on exposure to light and should be **stored** in well-stoppered bottles in the dark.

Almost **insoluble** in water; readily soluble in alcohol, ether, chloroform and the fixed and volatile oils.

Standard.—Carbon disulphide has a specific gravity of 1.268 to 1.272. Non-volatile residue on evaporation at 100° , not more than 0.01 per cent. Not less than 95 per cent. distils between 46° and 47° . Shaken with half its volume of water, the latter should not be acid to, or bleach, litmus (limit of acids and sulphur dioxide). When shaken with an equal quantity of lead acetate solution, no darkening occurs (limit of foreign sulphur compounds).

Action and Uses.—Carbon disulphide is not given internally to human beings. The vapour is sometimes applied locally to the skin for neuralgia, and to enlarged glands. For this purpose cotton wool placed in a wide-mouthed bottle is saturated with the liquid, and the mouth of the bottle is placed in contact with the part for a few minutes at a time. It is a powerful parasiticide, and is given internally to horses in doses of 8 to 16 millilitres (2 to 4 fluid drachms) for this purpose. Carbon disulphide is used as a solvent for sulphur, phosphorus and rubber.

In chronic **poisoning** by carbon disulphide, symptoms of peripheral neuritis are present, with hæmolytic, leucocytosis and anæmia.

CARBONEI TETRACHLORIDUM

(Carbon. Tetrachlor.)

Carbon Tetrachloride

Carbon tetrachloride is tetrachloromethane and may be prepared by passing a mixture of carbon disulphide vapour and chlorine through a red-hot porcelain tube; the resulting mixture of sulphur chloride and carbon tetrachloride is freed from the former by distillation with potassium hydroxide or milk of lime. It occurs as a heavy, colourless, volatile liquid, with a characteristic odour recalling that of chloroform, and a burning taste. It is non-corrosive and non-inflammable, but is decomposed by contact with a flame with the production of an acrid odour. When the vapour is introduced into a colourless flame, the latter is tinged green. It should be **stored** in well-closed bottles and protected from light.

Almost **insoluble** in water; miscible with dehydrated alcohol and ether.

Standard, B.P.—Carbon tetrachloride has a specific gravity of 1.603 to 1.606 and a boiling-range of 76.5° to 77.5°. Residue on evaporation on a water-bath, not more than 0.002 per cent. w/w. It complies also with limit tests for free acid, ionisable chloride, free chlorine, sulphur compounds and oxidisable impurities.

Action and Uses.—Carbon tetrachloride, when inhaled, acts as an anæsthetic, but, since it is more toxic than chloroform, it is not used for this purpose. The vapour has caused serious poisoning of a narcotic nature; in some cases, as for instance when inhaled from fire extinguishers containing carbon tetrachloride, the vapour may cause impairment of renal function and consequent suppression of urine. The presence of carbon disulphide increases its toxicity when inhaled. Carbon tetrachloride is used as an anthelmintic, especially for hookworms. To counteract its toxic action on the liver, its use should be preceded by the administration of liberal doses of calcium salts and dextrose, especially in the case of children. Alcohol should be avoided before and after treatment, and food should be withheld shortly before and after administration. It has also been used as a dry shampoo, but its use for this purpose is not unattended by danger, and deaths attributed to its action have been recorded. A solution of iodine in carbon tetrachloride has been used to sterilise the skin before operations. Carbon tetrachloride is also used in the treatment of liver fluke in sheep in doses of 1 millilitre (15 minims), but its use is occasionally followed by fatalities.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 drachm).

CARBROMALUM

(Carbrom.)

Carbromal

.Synonym—Uradal.

Carbromal is α -bromo- α -ethylbutyrylcarbamide, $\text{CBr}(\text{C}_2\text{H}_5)_2 \cdot \text{CO} \cdot \text{NH} \cdot \text{CO} \cdot \text{NH}_2$, and may be prepared by the action of α -bromo- α -ethylbutyryl bromide on urea. It occurs as a white, crystalline powder which is almost odourless and tasteless. When heated with dilute sodium hydroxide solution ammonia is evolved and sodium bromide formed.

Soluble in water (about 1 in 3000), more soluble in hot water, alcohol (95 per cent.) (about 1 in 18), ether (about 1 in 14) and chloroform (about 1 in 3); slightly soluble in light petroleum.

Standard, B.P.—Carbromal has a melting-point of 116° to 118° . Ash, not more than 0.05 per cent. It complies also with a test for neutrality and with limit tests for readily carbonisable substances, chloride and sulphate.

Action and Uses.—Carbromal is a prompt, efficient and safe sedative, and its administration is largely free from unpleasant symptoms. As a hypnotic it is less efficient than barbituric acid derivatives, but it possesses the advantage of being less toxic. It is commonly **administered** in tablets or cachets, and should be given, followed by a hot drink, thirty minutes before bedtime.

Dose.—0.3 to 1 gramme (5 to 15 grains).

CARDAMOMUM

(Cardam.)

Cardamom

Synonyms.—Cardamomi Semina; Cardamom Seeds.

Cardamom consists of the dried, ripe or nearly ripe seeds of *Elettaria Cardamomum* Maton var. *minuscule* Burkhill (Fam. Zingiberaceae), a plant growing wild in the forests of Southern India and cultivated on the Malabar Coast and in Ceylon. The seeds are imported loose or in the capsules from which they are removed when required for use.

The fruit is an inferior, ovoid or oblong capsule about 1 to 2 centimetres long; it is plump or slightly shrunken, the larger fruits being somewhat three-sided; externally it is smooth or longitudinally striated,

and pale buff to pale greenish-buff in colour; the remains of the flower parts form a short beak at the apex, while the base is rounded or shows the remains of the stalk; there are three loculi, each with two rows of seeds attached to an axile placenta and forming an adherent mass. The seeds are pale to dark reddish-brown, about four millimetres long and three millimetres broad, irregularly angular, hard, transversely rugose, the raphe lying in a longitudinal groove; each seed is enveloped by a thin, colourless, membranous aril. When cut transversely, the seed shows a thin, dark seed coat, a whitish perisperm grooved on one side and, in the centre, a yellowish, translucent endosperm, surrounding a small embryo. The odour and taste are agreeable and strongly aromatic.

The diagnostic **microscopical** characters are the polyhedral masses of adherent starch grains, individual grains being up to 4 microns in diameter; the presence of one to seven small prisms of calcium oxalate embedded in each starch mass; the layer of dark brown sclerenchyma, each cell being beaker-shaped, about 20 microns wide and 40 microns deep, with a small lumen nearly filled by a nodule of silica; the elongated cells of the outer epidermis; a few small spiral vessels and the absence of fibres, fibrous sclerenchyma and large vessels.

Cardamom **contains** a volatile oil, from about 3 to 8 per cent.; it also contains much starch. It yields to alcohol (45 per cent.) about 7 per cent. of extractive.

Varieties.—Mysore cardamom fruits form the bulk of the imports; they are ovoid in shape, vary from 10 to 20 millimetres in length, and have a pale cream, nearly smooth, surface. Malabar fruits are smaller, shorter and plumper, and often not so smooth as the foregoing. Mangalore fruits closely resemble Malabar fruits, but are usually almost globular, rather larger and often have a roughish, almost scurfy coat.

Substitutes.—Ceylon fruits, wild or native, derived from *E. Cardamomum* var. *major* Thwaites, are a regular article of commerce and are readily distinguished by their elongated shape, shrivelled appearance and rather dark greyish-brown colour.

Standard, B.P.—Cardamom is separated from the fruits when required for use. It contains not more than 3 per cent. of foreign organic matter. Ash, not more than 6 per cent.

Cardamom, in powder (*Pulvis Cardamomi*: *Pulv. Cardam.*), contains the constituents and possesses the diagnostic microscopical characters of *Cardamomum*, and complies with the limit for ash of the unground drug.

Action and Uses.—Cardamom, on account of its carminative properties, is administered with purgatives, as in *Extractum Colocynthis Compositum*, and with other aromatics, as in *Pulvis Cinnamomi Compositus* and *Pulvis Cretæ Aromaticus*. *Tinctura Cardamomi Composita* is the most commonly used cordial and flavouring agent. Together with cinnamon, clove, caraway and ginger, cardamom is also contained in *Tinctura Cardamomi Aromatica*, a more aromatic preparation than the compound tincture of cardamom.

Dose.—0.6 to 2 grammes (10 to 30 grains).

Preparations

Tinctura Cardamomi Aromatica, B.P.C.—(Tinct. Cardam. Aromat.)—Aromatic Tincture of Cardamom. *Syn.*—Tinctura Carminativa; Carminative Tincture. Cardamom, about 1 in 16, with strong tincture of ginger and oils of caraway, cinnamon and clove. Dose.—0·12 to 0·6 millilitre (2 to 10 minims).

Tinctura Cardamomi Composita, B.P.—(Tinct. Cardam. Co.)—Compound Tincture of Cardamom. Cardamom, 1·4 per cent. w/v, with caraway, cinnamon, cochineal and glycerin, prepared by percolation with alcohol (60 per cent.). Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

CARMINUM

(Carmin.)

Carmine

Carmine is the aluminium lake of the colouring principle of cochineal and may be prepared by precipitating an aqueous infusion with alum. It occurs in light, bright red pieces, which can readily be reduced to powder. Carmine contains about 50 per cent. of carminic acid. On heating, it gives an odour of burnt feathers. It should be **stored** in well-stoppered, amber-coloured bottles.

Insoluble in water and dilute acids; readily soluble in solution of ammonia and alkaline liquids, forming a dark purplish-red solution.

Standard.—Carmine yields not more than 10 per cent. of ash, calculated on the substance dried at 100°. Loss on drying at 100°, not more than 15 per cent. 0·1 gramme added to 1 millilitre of solution of ammonia and diluted to 100 millilitres with water forms a clear solution (limit of insoluble matter).

Uses. Carmine is used to colour ointments, tooth powders, tooth washes, dusting powders and other similar preparations. If used in solid form, prolonged trituration with powder is necessary to obtain a good colour and even distribution. To obtain the maximum of colour the carmine should be dissolved in a small quantity of strong solution of ammonia and triturated with the powder. A good solution for colouring neutral or alkaline mouth-washes and mixtures is Liquor Carmini, an ammoniacal aqueous solution, of which 3 or 4 drops to a fluid ounce of liquid is sufficient. The colouring matter of Liquor Carmini is precipitated in acid solutions. Carmine is used for staining histological specimens. Since it passes through the stomach unchanged, it is also used to indicate the rate of passage of intestinal contents.

Preparations

Glycerinum Carmini, B.P.C.—(Glycer. Carmin.)—Glycerin of Carmine. Carmine, 1 in 16, with potassium carbonate and potassium citrate in glycerin and distilled water

Liquor Carmini, B.P.C. (Liq. Carmin.)—Solution of Carmine. Carmine, 6 per cent. w/v, with dilute solution of ammonia and potassium citrate in glycerin and distilled water.

CARUM

(Carum)

Caraway*Synonyms*—Carui Fructus; Caraway Fruit; Caraway Seed.

Caraway consists of the dried, ripe fruits of *Carum Carvi* Linn. (Fam. Umbelliferæ), an erect biennial herb indigenous to and cultivated in Central and Northern Europe, chiefly in Holland. The plant is cut when the fruit is ripe, and the fruits obtained by threshing.

The fruit is an elongated cremocarp, but the two mericarps are usually separate and detached from the pedicel. Each mericarp is up to about 7 millimetres in length and 2 millimetres in breadth, slightly curved and tapering towards each end; the surface is glabrous and brown and is traversed longitudinally by five narrow, yellowish, primary ridges; in the tissue between the ridges are six vittæ, four on the dorsal surface and two on the commissure. The pericarp is thin and the large oily endosperm is not grooved on the commissure. The drug has a characteristic aromatic odour and taste.

The diagnostic **microscopical** characters are the thick-walled epidermal cells with striated cuticle; the small vessels, pitted sclerenchyma and fibres of the vascular tissue; the somewhat thick-walled parenchymatous cells of the endosperm, containing fixed oil, aleurone grains up to 10 microns in diameter and microspheroidal crystals of calcium oxalate; the absence of lignified and reticulate parenchyma.

Caraway **contains** 3·5 to 6 per cent. of volatile oil, containing about 50 per cent. of carvone; it also contains fatty oil. It yields to cold water from 20 to 26 per cent. of non-volatile extractive.

Substitutes and Adulterants.—Fruits from which the volatile oil has been partially removed are sometimes offered; they may be recognised by their dark colour, shrivelled appearance, want of aroma and low yield of aqueous extractive (less than 15 per cent.)

Standard, B.P.—Caraway contains not more than 2 per cent. of foreign organic matter. Ash, not more than 9 per cent. Acid-insoluble ash, not more than 1·5 per cent.

Caraway, in powder (Pulvis Cari : Pulv. Cari), contains the constituents and possesses the diagnostic microscopical characters of Carum, and complies with the limits for ash and acid-insoluble ash of the unground drug.

Action and Uses.—Caraway is a carminative. Caraway water is a useful remedy in the flatulent colic of infants and an excellent vehicle for children's medicines.

Dose.—0·6 to 2 grammes (10 to 30 grains).

Preparations

Aqua Cari Concentrata, B.P.C.—(Aq. Cari Conc.)—Concentrated Caraway Water. Oil of caraway, 1 in 50. One part added to 39 parts of distilled water yields a preparation which is approximately equivalent in strength to distilled caraway water, but contains 1·5 per cent. v/v of alcohol (90 per cent.) Dose—0·3 to 1 millilitre (5 to 15 minims).

Aqua Cari Destillata, B.P.C.—(Aq. Cari Dest.)—Distilled Caraway Water. Caraway, 1 in 10. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

This water was included in the British Pharmacopœia, 1914, under the name of Aqua Carui.

CARYOPHYLLUM

(Caryoph.)

Clove

Synonyms—Caryophyllus; Cloves.

Clove consists of the dried flower-buds of *Eugenia aromatica* (Linn.) Baill. (Fam. Myrtacæ), an evergreen tree indigenous to and formerly cultivated in the Molucca Islands, but now cultivated chiefly in Zanzibar and Pemba. The flower-buds are white when young, becoming green and then crimson during ripening. They are then collected and dried in the sun.

The flower-bud is from 10 to 17·5 millimetres long, of a reddish-brown colour and heavier than water. The lower portion consists of a slightly flattened four-sided hypanthium, which exudes oil when pressed with the finger-nail and contains, in its upper part, two loculi in which are numerous ovules on axile placentæ. The hypanthium is crowned by four thick, acute, divergent sepals within which is a dome-shaped head consisting of four paler, unexpanded, membranous, imbricate petals enclosing numerous incurved stamens and a single, stiff, erect style. The drug has a strong, aromatic, spicy odour and a pungent taste.

The diagnostic **microscopical** characters are the epidermis of the hypanthium and calyx teeth composed of straight-walled cells and showing large stomata; the tetrahedral pollen grains, 15 to 20 microns in diameter; the fibrous layer of the anther walls; the schizo-lysigenous glands found in all parts of the clove; occasional isolated pericyclic fibres; the spongy tissue of the hypanthium; the cluster-crystals of calcium oxalate, varying from 6 to 20 microns in diameter; the absence of stone cells, starch and prismatic crystals of calcium oxalate.

Clove **contains** from 15 to 20 per cent. of volatile oil, of which about 85 to 92 per cent. consists of eugenol. The drug also contains gallotannic acid (13 per cent.), fatty oil, resin and a crystalline body, caryophyllin, which, however, is odourless and appears to be a phytosterol.

Varieties.—The bulk of the supplies of clove come from Zanzibar, but Penang, Amboyna and Madagascar cloves command higher prices. Penang clove is larger, more plump, and bright reddish-brown in colour. Amboyna clove is similar but smaller, while Zanzibar clove is smaller still, darker in colour and less fragrant.

Substitutes and Adulterants.—"Blown" cloves are the expanded flowers from which the petals and stamens have been removed. Clove "dust" often consists largely of broken stamens, petals, etc. Clove stalks are up to about 3·5 centimetres in length and 3 millimetres in thickness and branch trichotomously, they are brownish and woody and break with a short fracture, they contain about 5 to 7 per cent. of volatile oil, which is less aromatic and somewhat different from that of clove. Clove stalks

are said to be used for adulterating powdered cloves, in which their presence is easily detected by means of the isodiametric sclerenchymatous cells and by the higher proportion of ash and the prismatic crystals of calcium oxalate. The nearly ripe fruits are also exported under the name "mother cloves" (anthophylli); they contain very little volatile oil and their presence may be detected by the large starch grains which the seeds contain. Exhausted clove, from which the oil has been removed by distillation, yields no oil when indented with the finger-nail and floats when placed on water.

Standard, B.P.—Clove contains not more than 5 per cent. of its stalks and not more than 1 per cent. of foreign organic matter. Ash, not more than 10 per cent. Acid-insoluble ash, not more than 0.75 per cent. It complies also with tests for limit of stalks and for absence of clove fruits and cereals.

Clove, in powder (*Pulvis Caryophylli* : *Pulv. Caryoph.*), contains the constituents and possesses the diagnostic microscopical characters of *Caryophyllum*, and complies with the limits for ash, acid-insoluble ash, stalks, clove fruits and cereals of the unground drug.

Action and Uses.—Clove is stimulating and carminative to the alimentary canal; it is used in flatulence, dyspepsia and as an adjuvant to other medicines. Fresh infusion of clove contains the astringent matter as well as some of the volatile oil; the infusion and water are useful vehicles for alkalis and aromatics.

Dose.—0.12 to 0.3 gramme (2 to 5 grains).

Preparations

Aqua Caryophylli Concentrata, B.P.C.—(*Aq. Caryoph. Conc.*)—Concentrated Clove Water. Oil of clove, 1 in 50. One part added to 39 parts of distilled water yields a preparation which is approximately equivalent in strength to distilled clove water, but contains 1.5 per cent. v/v of alcohol (90 per cent.). Dose.—0.3 to 1 millilitre (5 to 15 minims).

Aqua Caryophylli Destillata, B.P.C.—(*Aq. Caryoph. Dest.*)—Distilled Clove Water. Clove, 1 in 40. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Infusum Caryophylli Concentratum, B.P.—(*Inf. Caryoph. Conc.*)—Concentrated Infusion of Clove. Clove, about 1 in 5, extracted with alcohol (25 per cent.). This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh infusion of clove and differs also in containing a small proportion of alcohol. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

A concentrated infusion prepared with alcohol (20 per cent.) was included in the British Pharmaceutical Codex, 1923.

Infusum Caryophylli Recens, B.P.—(*Inf. Caryoph. Rec.*)—Fresh Infusion of Clove. 1 in 40. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

CASCARA SAGRADA

(*Casc. Sagr.*)

Cascara Sagrada

Synonym—Sacred Bark.

Cascara sagrada is the dried bark of *Rhamnus Purshiana* DC. (Fam. *hamnaceæ*), a shrub growing in North California, Oregon,

Washington and British Columbia. It is collected in the spring and early summer and dried, the collection being made at least one year before the bark is used.

The bark occurs in quilled, channelled or nearly flat pieces from 1 to 4 millimetres thick, varying in length up to about 10 or 20 centimetres and in breadth up to about 2 centimetres. The outer surface is nearly smooth, the cork being dark purplish-brown in colour and bearing scattered lenticels; it is usually more or less completely covered by a whitish coat of lichens. The inner surface is yellow to reddish-brown or nearly black, with longitudinal striations and faint transverse corrugations. The fracture is short and somewhat fibrous near the inner surface. The smoothed, transverse section exhibits a narrow, purplish cork, a yellowish-grey cortex, in which are darker, translucent groups of sclerenchymatous cells, and a brownish-yellow phloem traversed by slightly wavy medullary rays. The bark has a characteristic odour and a nauseous and persistently bitter taste.

The diagnostic **microscopical** characters are the groups of sclerenchymatous cells in both cortex and phloem; the bundles of slender phloem fibres, accompanied by crystal-sheaths with prisms of calcium oxalate; the cluster-crystals of calcium oxalate scattered throughout the parenchyma, the cells of which contain a yellow substance coloured violet by sodium hydroxide solution.

Cascara sagrada **contains** emodin and an isomeric substance, probably identical with the frangula-emodin of alder buckthorn bark. Fat (about 2 per cent.), dextrose and a hydrolytic enzyme have also been found in it, as well as a small quantity of a substance yielding, on treatment with acids, syringic acid. Neither chrysophanic acid nor chrysarobin is present. The total amount of hydroxymethyl-anthraquinones present in the bark, or extractable after boiling with dilute sulphuric acid, has been estimated to be from 1.4 to 4 per cent., but although these bodies are laxative, the principal purgative constituent of cascara sagrada is unknown. It yields to water from about 23 to 28 per cent. of extractive.

Substitutes and Adulterants.—The bark of *R. californica* Eschscholz is occasionally substituted for the official drug. It has a dull grey, slightly reddish cork, fewer lenticels and a uniform coat of lichens. The bark of *R. cathartica* Linn. is glossy, reddish-brown and has very distinct lenticels.

Standard, B.P.—Cascara sagrada contains not more than 2 per cent. of foreign organic matter. Ash, not more than 6 per cent.

Cascara sagrada, in powder (*Pulvis Cascaræ Sagradæ* : *Pulv. Casc. Sagr.*), contains the constituents and possesses the diagnostic microscopical characters of *Cascara Sagrada*, and complies with the limit for ash of the unground drug.

Action and Uses.—Cascara sagrada is a mild laxative acting principally on the large intestine. It is a useful laxative in hæmorrhoidal conditions. Small repeated doses after meals are more effective in chronic constipation than a large dose taken at night. It may be **administered** in the form of *Extractum*

Cascaræ Sagradæ Liquidum, preferably in a mixture with alkalis, especially **Spiritus Ammoniæ Aromaticus**, flavoured with **Extractum Glycyrrhizæ Liquidum**. **Mistura Cascaræ Composita** is a suitable mixture on these lines. On account of its unpleasant taste, cascara sagrada is often prescribed as **Elixir Cascaræ Sagradæ** or **Syrupus Cascaræ Aromaticus**, or as the liquid extract enclosed in capsules. **Extractum Cascaræ Sagradæ Siccum** is used in tablet form either alone or with extracts of nux vomica and belladonna, or with aloin, extract of euonymus, or strychnine.

Dose.—1·2 to 4 grammes (20 to 60 grains).

Preparations

Elixir Cascaræ Sagradæ, B.P.—(**Elix. Casc. Sagr.**)—Elixir of Cascara Sagrada. An aqueous extract of cascara sagrada, 1 in 1, made less bitter with light magnesium oxide and flavoured with liquorice, soluble saccharin, oil of coriander, oil of anise, alcohol (90 per cent.) and glycerin. **Dose.**—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Extractum Cascaræ Sagradæ Liquidum, B.P.—(**Ext. Casc. Sagr. Liq.**)—Liquid Extract of Cascara Sagrada. **Syn.**—Fluid Extract of Cascara Sagrada. 1 in 1. It is prepared with distilled water and preserved by the addition of alcohol (90 per cent.). **Dose.**—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Extractum Cascaræ Sagradæ Siccum, B.P.—(**Ext. Casc. Sagr. Sicc.**)—Dry Extract of Cascara Sagrada. The aqueous percolate evaporated to dryness under reduced pressure and granulated. It should be stored in small, wide-mouthed, well-closed containers in a cool place. **Dose.**—0·12 to 0·5 gramme (2 to 8 grains).

Mistura Cascaræ Composita, B.P.C.—(**Mist. Casc. Co.**)—Compound Mixture of Cascara. Each fluid ounce contains 20 minims of liquid extract of cascara sagrada, 5 minims each of the tinctures of belladonna and nux vomica, with liquid extract of liquorice, aromatic spirit of ammonia, glycerin and chloroform water. **Dose.**—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Mistura Rhei et Cascaræ, B.P.C.—(**Mist. Rhei et Casc.**)—Rhubarb and Cascara Mixture. Each fluid ounce contains 4 grains of rhubarb, 12 grains of sodium bicarbonate and 20 minims of liquid extract of cascara sagrada, with liquid extract of liquorice, syrup of ginger, oil of peppermint and chloroform water. **Dose.**—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Pilulæ Cascaræ Compositæ, B.P.C.—(**Pil. Casc. Co.**)—Compound Cascara Pills. **Syn.**—**Pilulæ Cascaræ, Belladonnæ et Nucis Vomicae**. Each pill contains $\frac{1}{4}$ grain of dry extract of cascara, and $\frac{1}{16}$ grain each of the dry extracts of belladonna and nux vomica. **Dose.**—1 to 3 pills.

Syrupus Cascaræ Aromaticus, B.P.C.—(**Syr. Casc. Aromat.**)—Aromatic Syrup of Cascara. Liquid extract of cascara, 1 in 2 $\frac{1}{2}$, with tincture of orange, alcohol (90 per cent.), cinnamon water and syrup. **Dose.**—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

This syrup was included in the British Pharmacopœia, 1914.

CASCARILLA

(**Cascaril.**)

Cascarilla

Synonym—Cascarilla Bark.

Cascarilla is the dried bark of *Croton Eluteria* Benn. (Fam. Euphorbiacæ), a small tree indigenous to the Bahama Islands.

The bark occurs usually in single quills or channelled pieces varying from about 2·5 to 7·5 centimetres in length and from 4 to 12 millimetres in width. The outer surface of the cork is chalky in appearance and frequently bears the minute, black fructifications of ascolichens; it is longitudinally wrinkled, chequered in places due to small transverse and longitudinal cracks, and the cork easily exfoliates, revealing a brown or grey-brown cortex marked with corresponding fissures. The inner surface is longitudinally striated and dark brown in colour; the fracture is short and resinous. The smoothed transverse surface exhibits a narrow, pale yellowish-brown layer of cork, a light brown cortex and a dark brown phloem with irregular, angular projections towards the cortex and with numerous, thin, whitish lines of the medullary rays. The odour is pleasant and aromatic and the taste is bitter.

The diagnostic **microscopical** characters are the cork cells, polygonal in surface view, lignified, and showing a much thickened, stratified, outer wall and a thin inner one in which are embedded numerous small, prismatic crystals of calcium oxalate; the parenchyma of phelloderm, cortex and phloem containing either prismatic or cluster-crystals of calcium oxalate, starch grains, or droplets of oleo-resin; the phloem containing also secretion cells and fibres which are isolated or in small groups, the medullary rays which are one or two cells wide; the absence of stone cells.

Cascarilla **contains** about 1·5 to 2 per cent. of volatile oil [specific gravity, 0·904 to 0·931; optical rotation, $+8\cdot2^{\circ}$ to $-0\cdot5^{\circ}$ (100 mm. tube); refractive index at 20° , 1·488 to 1·498], the crystalline bitter principle, cascarillin, and betaine. The drug yields to 70 per cent. alcohol from 12 to 18 per cent. of extractive. Powdered cascarilla contains a smaller proportion of volatile oil than the unground drug.

Standard.—Cascarilla contains not more than 2 per cent. of foreign organic matter. Ash, not more than 11 per cent.

Cascarilla, in powder (Pulvis Cascarillæ: Pulv. Cascaril.), contains the constituents and possesses the diagnostic microscopical characters of Cascarilla, and complies with the limit for ash of the unground drug.

Action and Uses.—Cascarilla is an aromatic bitter and also possesses weak febrifugal properties. It is most frequently **administered** in the form of infusion or tincture. Tincture of cascarilla is an ingredient of bitter tonics, frequently with mineral acids. Cascarilla is also used in fumigating compounds on account of its aromatic odour while burning.

Preparations

Infusum Cascarillæ Concentratum, B.P.C.—(Inf. Cascaril. Conc.)—Concentrated Infusion of Cascarilla. About 1 in 2½. This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh infusion of cascarilla and differs also in containing a small proportion of alcohol. Dose:—2 to 4 millilitres (½ to 1 fluid drachm).

Infusum Cascariillæ Recens, B.P.C.—(Inf. Cascaril. Rec.)—Fresh Infusion of Cascariilla. 1 in 20. When infusion of cascariilla or Infusum Cascariillæ is prescribed, fresh infusion not being specified, either Infusum Cascariillæ Recens, or Infusum Cascariillæ Concentratum suitably diluted, may be dispensed. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

This infusion was included in the British Pharmacopœia, 1914, under the name of Infusum Cascariillæ.

Tinctura Cascariillæ, B.P.C.—(Tinct. Cascaril.)—Tincture of Cascariilla. 1 in 5. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopœia, 1914.

CASEINUM SOLUBILE

(Casein. Solub.)

Soluble Casein

Soluble casein is a compound of casein with a small proportion of alkali. It may be prepared by mixing precipitated casein, while still moist, with powdered sodium carbonate, the product being dried at a low temperature. It occurs as a white or yellowish-white, non-hygroscopic, almost odourless powder, with a characteristic taste. Casein is a protein occurring in milk and may be prepared from skimmed milk by the addition of acid or by the action of rennet. The protein clot is separated from the whey, washed, and dried at a low temperature. Casein is a phosphoprotein and a weak dibasic acid, forming acid or neutral salts with alkalis. It contains about 15 per cent. of nitrogen, about 0.9 per cent. of phosphorus and about 0.8 per cent. of sulphur. Casein as it exists in milk (sometimes termed caseinogen), or as prepared by the action of rennet, contains calcium. It is hardened to a horn-like consistency by the action of formaldehyde. Various grades are prepared for technical purposes, with or without the addition of alkalis or borax to increase the solubility.

Almost entirely **soluble** in water.

Standard.—Soluble casein, determined by the Kjeldahl method, contains not less than 12 per cent. of N, calculated on the substance dried at 100°. Loss on drying at 100°, not more than 10 per cent. Ash, not more than 5 per cent. The ash, dissolved in water and slightly acidified with hydrochloric acid, does not cause turmeric paper dipped in the solution to assume a red or brownish-red colour on drying (absence of borax). 3 grammes stirred with 20 millilitres of water at 30° forms a smooth mucilaginous solution within fifteen minutes. When 1 gramme is dissolved in 20 millilitres of water and the casein is precipitated with a slight excess of hydrochloric acid, the filtrate, after neutralisation with sodium hydroxide solution, gives not more than a trace of red precipitate on boiling with 5 millilitres of Fehling's solution (limit of lactose).

Action and Uses.—Casein or soluble casein is the chief constituent of various nutritive preparations, sometimes mixed with ovoidlecithin or with the glycerophosphates of sodium, calcium, magnesium and iron,

and is also a constituent of many diabetic and protein foods. Soluble casein has the advantage of being more readily miscible with water than ordinary casein and is more easily digested. Casein is sometimes employed as a basis of non-greasy skin-creams, these usually being prepared with an alkali carbonate and mucilage of tragacanth or quince, and containing zinc oxide or other suitable medicament. Pure casein, dissolved with the aid of hydrochloric acid or 0.1 per cent. w/v solution of sodium hydroxide, is employed for determining the activity of peptic and tryptic ferments.

Casein is used largely in many industries; it is an ingredient of paste and dry distempers, glues and sizes. Insoluble casein, treated with formaldehyde and subjected to heavy pressure, gives a very hard material which by addition of various pigments gives imitations of bone, ivory, ebonite and other similar substances. Casein is generally the only source of protein in the vitamin A-free diet of rats used for testing for vitamin A. The sample used must therefore be a perfect protein; that is, it must contain all the amino-acids which have been shown to be necessary for growth. It should be tested by a special experiment; rats should be given this diet supplemented liberally with the lacking vitamin; if growth is not normal, the casein must be considered inadequate. It should also be free from detectable traces of vitamin A, although for tests of vitamin A the presence of vitamin B in the casein is immaterial. On the other hand, when casein is the source of protein in diets used for vitamin B tests, it should be free from this vitamin, but not necessarily free from vitamin A. Soluble casein is **incompatible** with acids.

Preparation

Caseinum Glycerophosphaticum, B.P.C.—(Casein. Glycerophosph.)—Glycerophosphated Casein. Soluble casein, with sodium and calcium glycerophosphates, of each, 1 in 40. Dose.—4 to 16 grammes (1 to 4 drachms).

CASSIÆ CORTEX

(Cass. Cort.)

Cassia Bark

Synonym—Chinese Cinnamon.

Cassia bark is obtained from *Cinnamomum Cassia* Blume (Fam. Lauracæ), an evergreen tree indigenous to Cochin China and the South of China, but cultivated also in other parts of Eastern Asia.

The bark occurs in single quills or channelled pieces from 5 to 40 centimetres long, 12 to 18 millimetres in diameter, and 1 to 3 millimetres thick. The colour is dark earthy-brown, except where patches of thin, greyish cork persist. The fracture is short and granular in the outer part, but slightly fibrous in the inner part. The smoothed transverse surface of thicker pieces shows a pale zone of pericyclic stone cells at varying depths from the outer surface, and to the inside a brown

phloem traversed by thin, paler medullary rays. The transverse section is characterised by an interrupted ring of sclereides, many cells of which have walls more thickened on three sides, the cells of the medullary rays, many of which contain short needle crystals of calcium oxalate, isolated or grouped sclerenchymatous fibres mostly from 30 to 40 microns wide, and secretion-cells. Starch grains are abundant, mostly over 10 microns in diameter. The odour is like that of cinnamon, but less delicate, and the taste more mucilaginous and astringent.

Cassia bark **contains** from 1 to 2 per cent. of volatile oil. It also contains tannin, sugar and mucilage.

Action and Uses.—Cassia bark has properties similar to those of cinnamon; it is mildly astringent, carminative and antiseptic. Oil of cassia is used as a substitute for oil of cinnamon, which it closely resembles in its medicinal properties.

CASSIÆ FLOS.—Cassia bud consists of the immature fruits of species of *Cinnamomum*, probably *C. Cassia* Blume and *C. Loureirii* Nees, the so-called buds being shipped from Canton. Cassia buds are about 6 to 10 millimetres long and 5 millimetres in diameter at the widest point; each consists of a short stalk, about 1 to 2 millimetres long, supporting a small, vertically flattened fruit which is almost completely enclosed by the six persistent, incurved, rounded perianth parts arranged in two whorls of three and united below to form a stalk-like portion about 3 millimetres long. They are hard, brown or greyish, woody and wrinkled; the odour and taste resemble those of cinnamon. Cassia bud contains about 1·6 per cent. of volatile oil, consisting principally of cinnamic aldehyde. It is used as a spice and for the same purposes as cinnamon.

CASSIÆ FRUCTUS

(Cass. Fruct.)

Cassia Fruit

Synonym —Cassia Pod.

Cassia fruit consists of the ripe fruits of *Cassia Fistula* Linn. (Fam. Leguminosæ), a tree indigenous to India.

The fruit is a many-celled, indehiscent pod, from 35 to 50 centimetres long and from 18 to 25 millimetres in diameter, nearly straight and sub-cylindrical in shape and dark chocolate-brown to almost black in colour. The surface of the pod appears smooth to the naked eye, but is seen under the lens to be marked with minute transverse fissures. Both dorsal and ventral sutures are evident, but not prominent. A short stalk is attached to the base of the fruit, and the rounded distal end is mucronate. The pericarp is thin, hard and woody. The interior of the fruit is divided by transverse dissepiments, about 6 millimetres apart, into compartments, each of which contains a single seed attached to the ventral suture by a long, dark, thread-like funicle. The seeds are about 8 by 10 by 2·5 millimetres, ovoid and flattened in shape, of a shining reddish-brown colour, smooth and extremely hard; they are imbedded in a black, viscid pulp which at first fills the cell, but, on drying, shrinks and is found adhering to both sides of the dissepiments,

the seeds being then often loose in their cells. The pulp has a sweetish taste and a faint sickly odour.

Cassia fruit **contains** mucilage, pectin, hydroxymethylantraquinones and a large proportion of sugar.

Substitutes.—The fruit of *Cassia grandis* Linn. (horse cassia), from Brazil and Central America, is usually longer, thicker and heavier than that of *C. Fistula*. The surface is rough and the fruit laterally compressed, being elliptical in cross section. It has one prominent ridge on the dorsal and two on the ventral suture. The fruit of *C. moschata* H.B. & K., from New Granada, is smaller and narrower than that of *C. Fistula*. The pulp is paler in colour and has a musky odour when warmed.

Standard.—Cassia fruit yields to water not less than 30 per cent. of extractive.

Action and Uses.—The aqueous extract, known as cassia or cassia pulp, is laxative and is an ingredient of confection of senna; it is rarely used alone.

Preparation

Cassia, B.P.—(Cass.)—Cassia. *Syn.*—Cassia Pulp; Cassia Pulp. The pulp of cassia fruit extracted by percolation with water and evaporation of the percolate to the consistence of a soft extract. Dose—4 to 8 grammes (1 to 2 drachms).

CASTOREUM

(Castor.)

Castor

Castor consists of the dried follicles obtained from the beaver, *Castor fiber* Linn. (Order, Rodentia; Class, Mammalia), found chiefly in the Hudson Bay Territory. The follicles are situated between the anus and external genitals of both sexes of the animal, where two pairs of membranous sacs occur, the anterior and larger pair constituting the drug, the remaining pair being the anal glands. The follicles are either dried in the sun or smoked.

The drug occurs in dark brownish or greyish, pear-shaped masses, about 8 to 10 centimetres long, usually in pairs, connected by a portion of the preputial or vaginal canal. The follicles are firm, heavy and solid, and are divided internally into numerous cells, which contain a brown or reddish-brown, resinous secretion which when fresh, is soft and pale in colour, becoming hard and dark with age. The odour is empyreumatic and somewhat disagreeable. When examined microscopically, spherical grains of crystalline calcium carbonate are to be found in the resinous mass. Russian castor is larger, fuller and heavier than the North American variety; the contents have a stronger and more agreeable odour. Adulteration has been effected by emptying the sacs and filling with brown wood fibre, dried blood, resin, etc.

Castor **contains** from 35 to 70 per cent. of resinous matter soluble in alcohol, about 8 per cent. of ether-soluble fatty matter and a variable amount of moisture. The odour is due to the presence of a volatile oil.

Action and Uses.—Castor had a reputation formerly for the treatment of dysmenorrhœa and hysterical conditions. It is **administered** principally as Tinctura Castorei, which may be given in mixture form with a little mucilage to suspend the resin and with tincture or infusion of valerian.

Preparation

Tinctura Castorei, B.P.C.—(Tinct. Castor.)—Tincture of Castor. 1 in 20.
Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

CATECHU

(Catech.)

Catechu

Synonyms—Pale Catechu; Gambir.

Catechu is a dried aqueous extract prepared from the leaves and young shoots of *Uncaria Gambier* (Hunter) Roxb. (Fam. Rubiaceæ), a climbing shrub indigenous to and cultivated in the Malay Archipelago. The leaves and young shoots are boiled with water, and the decoction evaporated to a thick syrup and cooled, crystallisation being promoted by stirring; the product is poured into shallow, wooden trays, allowed to set, cut up into cubes and dried.

The extract occurs in cubes, which are sometimes more or less agglutinated and mixed with fragments of broken cubes; they are friable and porous, and measure about 25 millimetres in each direction. Their colour is dull, pale greyish-brown to dark reddish-brown externally and pale brown internally. Examined microscopically, catechu is seen to consist chiefly of minute acicular crystals. Catechu may be distinguished from black catechu by the following tests:—Mix 2 millilitres of a filtered and cooled 15 per cent. solution in warm alcohol with an equal volume of sodium hydroxide solution, shake with 2 millilitres of light petroleum and allow to separate; the light petroleum layer exhibits a brilliant greenish fluorescence. Warm catechu with chloroform and filter; a yellowish-green solution is produced.

Catechu **contains** catechin (7 to 33 per cent.), and catechutannic acid (22 to 50 per cent.). In addition to these, quercetin, wax, oil, catechu-red and a fluorescent body, named gambier-fluorescein, occur in small quantities. The drug also contains vegetable debris and mineral matter (about 3 to 5 per cent.). Catechin, $C_{15}H_{14}O_6 \cdot 4H_2O$, which is not identical with the acacatechin of cutch, occurs in white, silky needles melting at 96° ; the monohydrate, obtained by drying over sulphuric acid, melts at 176° to 177° , and this is also the melting-point of the anhydrous substance. There is also present a small amount of catechin-c, which is anhydrous and melts at 235° to 237° . Catechin is sparingly soluble in cold water (1 in 1100 to 1200), but freely soluble in boiling water and alcohol, and produces with ferric salts a deep green colour. Catechu tannic acid is a reddish, amorphous, astringent substance,

which precipitates gelatin and is coloured dirty green by ferric salts. On boiling the aqueous solution, with or without a mineral acid, it is converted into a reddish-brown, amorphous substance.

Standard, B.P.—Catechu yields not more than 25 per cent. of water-insoluble matter, dried at 100°. Loss on drying at 100°, not more than 10 per cent. Alcohol-insoluble matter, dried at 100°, not more than 30 per cent.; the alcohol-insoluble matter contains not more than an occasional starch grain. Ash, not more than 8 per cent. It complies with a test with solution of calcium hydroxide.

Catechu, in powder (*Pulvis Catechu* : *Pulv. Catech.*), contains the constituents and possesses the diagnostic microscopical characters of Catechu, and complies with the standard for the unground drug.

Action and Uses.—Catechu is a powerful astringent. It is used internally, in association with other astringents as *Pulvis Catechu Compositus* and as *Tinctura Catechu*, in diarrhœa and hæmorrhage from the alimentary canal. The compound powder may be administered in cachets, or in mixtures with sedatives; the tincture is generally used in conjunction with chalk, opium, or ginger. Catechu lozenges are used for their astringent action in the mouth and throat, and the tincture, diluted 1 in 25, may be used as a gargle. Preparations of catechu are **incompatible** with gelatin, iron salts and alkalis.

Dose.—0·3 to 1 gramme (5 to 15 grains).

Preparations

Pulvis Catechu Compositus, B.P.C.—(*Pulv. Catech. Co.*)—Compound Powder of Catechu. Catechu, 1 in 2½, with kino, krameria, cinnamon and nutmeg. Dose. 0·6 to 4 grammes (10 to 60 grains).

This powder was included in the British Pharmacopœia, 1914.

Tinctura Catechu, B.P.—(*Tinct. Catech.*)—Tincture of Catechu. Catechu, 1 in 5, with cinnamon, prepared by maceration with alcohol (45 per cent.). Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

Trochisci Catechu, B.P.C.—(*Troch. Catech.*)—Catechu Lozenges. Each lozenge contains 1 grain of catechu.

This lozenge, containing 0·06 gramme of catechu, was included in the British Pharmacopœia, 1914.

CATECHU NIGRUM

(*Catech. Nig.*)

Black Catechu

Synonyms—Cutch; Kutch.

Black catechu is an extract prepared from the heartwood of *Acacia Catechu* Willd. (Fam. Leguminosæ), a moderate-sized tree indigenous to Eastern India and Burma. After felling, the bark and sapwood are stripped from the trunk and the dark red heartwood cut into chips and boiled in water in earthen pots; the decoction is strained and

boiled down, with continued stirring, to a syrupy consistence. When sufficiently cool, the syrup is poured into wooden moulds lined with leaves or paper, and left to harden. The resulting solid extract forms large, brick-like masses which are broken up into pieces of irregular shape.

The extract occurs in irregular, dark brown to almost black masses, externally rough and dull or, rarely, glossy, frequently having pieces of brownish-buff leaves attached to them. It is hard and brittle, but frequently soft internally. The fractured surface is dark brown with a dull gloss, and porous. The drug is odourless, and the taste at first bitter, becoming sweetish and astringent. It is partially soluble in water, yielding a brown magma which, when examined microscopically, exhibits numerous minute crystals. It is almost entirely soluble in boiling water, the solution on cooling giving a crystalline sediment. A 1 per cent. aqueous solution gives a dark green colour with 0.1 per cent. w/v ferric chloride solution, changing to purple when made slightly alkaline with 5 per cent. sodium hydroxide solution. It does not respond to the test for gambier fluorescein described under catechu.

Black catechu **contains** catechutannic acid (25 to 35 per cent.), acacatechin (2 to 10 per cent.), quercetin, and catechu red.

Substitutes.—Mangrove cutch is a similar extract and is made from the bark of *Rhizophora Mangle* Linn., and of *Ceriops Candolleana* Arn. (Fam. Rhizophoraceæ).

Standard.—Black catechu yields to alcohol (90 per cent.) not less than 60 per cent. of extractive. Ash, not more than 8 per cent.

Black catechu, in powder (Pulvis Catechu Nigri: Pulv. Catech. Nig.), contains the constituents and possesses the diagnostic microscopical characters of Catechu Nigrum, and complies with the standard for the unground drug.

Action and Uses.—Black catechu resembles pale catechu in its properties and is employed for similar purposes.

Dose. 0.3 to 1 granule (5 to 15 grains).

CAULOPHYLLUM

(Cauloph.)

Caulophyllum

Synonyms—Blue Cohosh; Caulophyllum Rhizome; Papoose Root; Squaw Root.

Caulophyllum consists of the rhizome and roots of *Caulophyllum thalictroides* (Linn.) Mich. (Fam. Berberidaceæ), a herbaceous plant growing in the United States.

The rhizome is horizontal, greyish-brown, about 5 to 20 centimetres long and 5 to 12 millimetres thick, irregular, somewhat tortuous and

branched, and bears encircling scale-leaf scars. The upper surface bears cup-shaped depressions and remains of aerial stems. The numerous, wiry, nearly cylindrical, smooth, matted roots arise from all parts of the surface, and are about 10 centimetres long and 1 to 3 millimetres in diameter. The transversely cut surface of the rhizome is brownish-grey and horny, with a thin bark and a ring of numerous narrow wedges of wood surrounding a large pith. Starch is present in the broad medullary rays and in the pith. The fracture is short. Caulophyllum is odourless, but sternutatory, and the taste is bitter and acrid.

Caulophyllum **contains** two saponins, leontin (caulosaponin) and caulophyllosaponin, the alkaloid, methylcytisine (caulophylline), and resin. The alkaloid must not be confused with the brown resinous powder, caulophyllin, which is obtained by precipitation from a concentrated alcoholic tincture of the drug. It yields to alcohol (70 per cent.) about 25 per cent. of extractive.

Standard.—Caulophyllum contains not more than 3 per cent. of foreign organic matter. Acid-insoluble ash, not more than 4 per cent.

Action and Uses.—Caulophyllum is used as a diuretic and emmenagogue, and is stated to exert a direct influence on the uterus. It has been used with success as an anthelmintic. It is usually **administered** as Extractum Caulophylli Liquidum and frequently with pulsatilla, or pulsatilla with aletris and black haw, as Liquor Caulophylli et Pulsatillæ or Liquor Caulophylli et Pulsatillæ Compositus.

Dose.—0.3 to 2 grammes (5 to 30 grains).

Preparations

Extractum Caulophylli Liquidum, B.P.C.—(Ext. Cauloph. Liq.)—Liquid Extract of Caulophyllum. *Syn.*—Liquid Extract of Blue Cohosh. 1 in 1. Dose.—0.6 to 2 millilitres (10 to 30 minims).

Liquor Caulophylli et Pulsatillæ, B.P.C.—(Liq. Cauloph. et Pulsat.)—Solution of Caulophyllum and Pulsatilla. Liquid extract of caulophyllum, 1 in 4, and liquid extract of pulsatilla, 1 in 20, with glycerin and alcohol (60 per cent.). Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Liquor Caulophylli et Pulsatillæ Compositus, B.P.C.—(Liq. Cauloph. et Pulsat. Co.)—Compound Solution of Caulophyllum and Pulsatilla. Liquid extracts of caulophyllum, about 1 in 6, pulsatilla, 1 in 20, aletris, 1 in 10, and black haw, 1 in 5, with glycerin and alcohol (60 per cent.). Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

CERA ALBA

(Cera Alb.)

White Beeswax

White beeswax is obtained by bleaching yellow beeswax. The bleaching may be effected by exposing the wax in thin layers to the

action of air, sunlight and moisture, but is more usually accomplished by treatment with chemicals such as potassium dichromate and sulphuric acid. It occurs as hard, yellowish-white masses, translucent in thin layers, with a faint characteristic odour.

Standard, B.P.—White beeswax has an acid value of 18 to 24. In other respects it complies with the standard for Cera Flava.

Uses.—White beeswax is used in the preparation of emollient ointments, and occasionally to raise the melting-point of suppositories. Aseptic wax is used to arrest hæmorrhage in cranial surgery.

Preparations

Cera Aseptica, B.P.C.—(Cera Asep.)—Aseptic Wax. Salicylic acid, approximately 1 per cent., in a sterilised mixture of almond oil and white beeswax.

Unguentum Aquosum, B.P.—(Ung. Aquos.)—Hydrous Ointment. Distilled water, about 25 per cent., and borax, 1 per cent., in white beeswax, white soft paraffin and olive oil.

CERA FLAVA

(Cera Flav.)

Yellow Beeswax

Yellow beeswax is a secretion formed by the hive bee, *Apis mellifica* Linn., and possibly other species of *Apis* (Order, Hymenoptera), and used by the insect to form the cells of the honeycomb. After the extraction of the honey, the wax is melted with water, separated and strained. It occurs as a yellowish-brown solid, brittle when cold, breaking with a dull, granular fracture, but becoming plastic when warmed. It has an agreeable honey-like odour. Beeswax contains about 80 per cent. of myricin, or melissyl palmitate, $C_{15}H_{31} \cdot COOC_{30}H_{61}$, about 15 per cent. of cerotic acid, $C_{26}H_{53} \cdot COOH$, the aromatic body, cerolein, and probably some melissyl stearate. The ratio number is a useful criterion of purity and differs greatly from that of the common adulterants.

Insoluble in water; sparingly soluble in cold alcohol (90 per cent.); soluble in warm ether, chloroform and fixed and volatile oils.

Standard, B.P.—Yellow beeswax has a specific gravity of 0.958 to 0.970. Melting-point, 62° to 64° . Refractive index at 80° , 1.4380 to 1.4420. Acid value, 17 to 23. Ester value, 70 to 80. Ratio number (ester value divided by acid value), 3.3 to 4.0. It complies with tests for absence of fats, fatty acids, Japan wax, resin, ceresin, paraffin and certain other waxes.

Uses.—Yellow beeswax is used in the preparation of plasters and of ointments in which its yellow colour is not objectionable. A mixture of 9 parts of beeswax and 1 part of phenol is used for toothache. A mixture of equal parts of beeswax and hard paraffin, in which sawdust

has been incorporated, is known as Columbia wax, and is used for moulds in the application of radium needles.

CARNAUBA WAX is an exudation from the leaves of *Copernicia cerifera* Mart. (Fam. Palmæ), a palm indigenous to Brazil. The leaves are beaten and the wax collected, melted into a mass and purified. It occurs as a very hard, yellowish or greenish solid which is white when bleached. Melting-point, about 83° to 86°. Specific gravity, 0.990 to 0.999. Carnauba wax contains myricyl cerotate together with myricyl alcohol, cerotic acid and other substances. It is used in the manufacture of varnishes and polishes.

JAPAN WAX is a fat obtained from the berries of various species of *Rhus* (Fam. Anacardiaceæ), the trees being cultivated in China, Japan and California. It is obtained by crushing and steaming the berries, and is bleached by exposure to sunlight. It occurs as a pale yellow solid which becomes white externally on keeping. Melting-point, 50° to 60°. Specific gravity, 0.975 to 0.993. Japan wax contains chiefly palmitin and free palmitic acid. It is used in the manufacture of polishes.

CEREUS

(*Cereus*)

Cereus

Synonyms—Night-Blooming Cereus; Cactus Grandiflorus.

Cereus consists of the fresh, young shoots of *Cereus grandiflorus* Mill. (Fam. Cactaceæ), a native of the West Indies. It is usually imported preserved in spirit.

The drug consists mainly of the stems, which are angular, simple or rarely branched, 1 to 4 centimetres in diameter, dark green, deeply channelled longitudinally, and bear upon the ridges clusters of 6 to 8 prickly thorns 1 to 6 millimetres long. The transversely cut surface shows from 5 to 9 projecting angles and a large central hollow. The chief constituents of *cereus* are resins, the presence of the alleged alkaloid, cactine, not having been confirmed.

Substitutes.—The dried flowers of *Opuntia decumana* Haw. and other species of *Opuntia* are sometimes found in commerce and described as cactus flowers. These flowers are small, being 3 to 5 centimetres in diameter.

Action and Uses.—*Cereus* is supposed to act as a cardiac stimulant and as a partial substitute for digitalis, but there is no proof of its therapeutic value. It has been used in cases of dropsy and various cardiac affections, being administered in the form of liquid extract or tincture.

Preparations

Extractum Cerei Liquidum, B.P.C.—(Ext. Cerei Liq.)—Liquid Extract of *Cereus*. *Syn.*—Extractum Cacti Grandiflori Liquidum. 1 in 1. Dose.—0.06 to 0.6 millilitre (1 to 10 minims).

Tinctura Cerei, B.P.C.—(Tinct. Cerei)—Tincture of *Cereus*. *Syn.*—Tinctura Cacti Grandiflori. 1 in 4. Dose.—0.12 to 2 millilitres (2 to 30 minims).

CEREVISIÆ FERMENTUM

(Cerevis. Ferment.)

Yeast*Synonym*—Faex Medicinalis.

Yeast is an alcohol-forming, unicellular fungus belonging to the family *Saccharomycetaceæ*, a sub-division of the *Ascomycetes*. Several species are used in the fermentation industries, the chief being *Saccharomyces cerevisiæ* Meyen *emend.* Hansen, *S. Carlsbergensis* Hansen, and *S. monacensis* Hansen, of which many different strains and races exist. It is obtained from parent cells by growth in a suitable saccharine and nitrogenous medium (brewers' or distillers' wort).

Brewers' yeast occurs as a viscid, frothy mass, having a peculiar odour and bitter taste. Under the microscope it shows numerous isolated, roundish or oval cells, or short, branched filaments composed of united cells. The cells are transparent, about 7 microns in diameter, with one or two vacuoles; they often contain a somewhat granular protoplasm and increase by budding. Spores are formed under conditions of low nutrition and free aeration. Compressed distillers' yeast, or bakers' yeast, is obtained as a by-product in the manufacture of spirits from malt and raw grain. The skimmings from the fermentation vats are first mixed with water and then passed through a series of sieves. They are then washed by decantation two or three times and again sifted, this time through finer sieves. Finally, when the yeast has completely settled, it is placed in filter-presses, either alone or after admixture with a little starch. After compression, the yeast is separated from the press cloths and made up into convenient form for distribution. Bakers' yeast is also manufactured as the sole product in yeast factories. Large volumes of air are blown through the fermenting wort, a procedure which favours a maximum yeast production and removes the alcohol. Much of this yeast is imported and was formerly described as German yeast. Compressed distillers' yeast occurs as a pasty mass of putty-like consistence, but is occasionally of a crumbly nature. It has an odour similar to that of brewers' yeast and a pleasant, fruity flavour. Dried yeast is prepared by exposing yeast to a temperature of 30°. It occurs as a light grey powder and yields to alcohol about 3 per cent. of extractive.

The liquid (yeast juice) obtained by grinding yeast with sand and subjecting it to high pressure, or by macerating the dried yeast with water and filtering, **contains** the enzyme, zymase. This liquid decomposes solutions of many monosaccharides and disaccharides with production of alcohol and carbon dioxide. A large number of other enzymes are also present in the yeast cell, among them being invertase, which inverts sucrose, maltase, which converts maltose into dextrose, emulsin and a proteolytic endotryptase. Other constituents are fat, ergosterol, the mother substance of the antirachitic vitamin D, zymosterol, glycogen, various other carbohydrates, a considerable proportion of protein, some of which is combined with nucleic

acid to form substances known as nucleins and nucleo-proteins, glutathione, etc. Yeast is a valuable source of the vitamin B complex, being as valuable for vitamin B₁ as are rice polishings. The original vitamin B has been found to be a complex of several factors, perhaps six. Yeasts vary much in their potency, and in the case of a given yeast the stability of factors present may be much altered by details of procedure in the preparation of extracts or in the process of drying; therefore, it is wise to check the biological activity of any sample used. Both brewers' and bakers' yeasts contain vitamins B₁ and B₂ (or G). Vitamin B₁ is much less stable to heat and alkali than vitamin B₂. Hence temperature is an important factor in the drying of yeast; too high a temperature may lower the content of vitamin B₁. It also contains the yeast growth-promoting factor known as "bios."

Action and Uses. - When fresh yeast is given by the mouth it grows actively in the stomach, but its therapeutic action is not due to its property of inciting fermentation. It is given internally in cases of furunculosis. Its action resembles that of nuclein since, if injected, it increases the proportion of leucocytes after a transient leucopenia. Yeast is employed as a means of administering the B vitamins which are essential for growth. The antineuritic vitamin B₁ (anti beri-beri) has been shown to be of great importance to man. It is probable also that vitamin B₂ (anti-dermatitis for rats) has some relation to human pellagra. Yeast improves the appetite and increases intestinal peristalsis; it is, therefore, used in malnutrition, general debility and constipation. When irradiated with ultra-violet light, yeast acquires anti-rachitic properties owing to the conversion of ergosterol into vitamin D. Irradiated yeast may be used in the treatment of rickets and for other purposes for which irradiated ergosterol is employed.

Yeast may be **administered** in the form of compressed yeast shortly before meals, or the yeast cake may be given in suspension in water. Dried yeast may be given by the mouth in capsules or tablets, but large amounts are needed to ensure adequate dosage, and, owing to the necessity for digestion, liberation of all the contained vitamin may be slow. For quicker action (as in the treatment of acute symptoms of beri-beri), rapid absorption can be secured by using soluble extracts, atomysed yeast, or aqueous concentrates.

Dose. - 8 to 16 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ ounce) of compressed yeast; 2 to 4 grammes ($\frac{1}{2}$ to 1 drachm) of dried yeast.

VITAMIN B CONCENTRATES.—Aqueous concentrates of yeast suitable for administration by the mouth may be obtained by simple extraction of the yeast with water or 0.01 per cent. acetic acid solution. The yeast is stirred into twice its volume of boiling water, boiled for three minutes and then filtered. Such an extract will contain much of the vitamin B complex when it is prepared freshly, and is free from the yeast residue. Yeast extracts closely resemble meat extract in colour, taste and smell, and may be distinguished chemically by their freedom from creatinine. It is important to keep the extract slightly acid since vitamin B₁ is sensitive to small amounts of alkali. Alternatively, yeast may be extracted with sufficient alcohol to make a total concentration of from 50 to 70 per cent. Alcohol over 70 per cent. in strength is less efficient for extracting vitamin B₁, and especially B₂. The aqueous

extract, if necessary after removal of alcohol *in vacuo*, may be further purified by adsorption upon fuller's earth or charcoal at appropriate hydron concentration. Such treatment usually leaves behind vitamin B₂. The latter is thrown out by alcohol concentrations over 80 per cent., and is largely precipitated from aqueous solutions by neutral lead acetate, the B₁ remaining in solution. Concentrates of vitamin B₁ after the adsorption stage can be further purified by precipitation as the platinum or gold chloride compound. Concentrates of vitamin B may also be obtained from wheat-germ. Crystalline concentrates of vitamin B₁ have been obtained such that 0.01 milligram represents the amount of vitamin contained in approximately 1.0 to 2.0 grammes of fresh yeast, 0.3 to 0.4 gramme of a good dried yeast, or 0.3 gramme of an active concentrate.

The purer concentrates of vitamin B₁ are suitable for subcutaneous or intravenous injection, which is necessary when a rapid action is required. Material for injection should be tested biologically owing to the possible presence of other bases of physiological potency such as histamine, which may also be present in yeast extracts. Concentrates of vitamin B₁ from rice polishings have been used with success in the treatment of beri-beri in Java. Vitamin B₁ and B₂ preparations can be standardised by animal tests. For vitamin B₁, curative tests can be made upon pigeons and rats. Alternatively, comparisons with a standard of the amount of growth produced by the unknown preparation may be made with young rats feeding upon a diet complete except for the factor in question. Curative tests with pigeons are made on birds fed for three to four weeks on polished rice until symptoms of polyneuritis appear. The amount of vitamin B₂ can be estimated either by curing rats of the dermatitis produced by a diet free from vitamin B₂ or by growth tests in which this is the missing factor.

The standard for vitamin B₁ is the amount of vitamin B₁ in 10 milligrams of a specimen of Java activated clay (Jansen) kept by the National Institute for Medical Research, London. The dose of vitamin B₁ required by man can be computed approximately upon the assumption that a daily dose is supplied by 500 grammes of unpolished rice, or 35 grammes of rice polishings. The amount needed to provide all the necessary vitamin B₁ would be 3 to 6 grammes of dried yeast, or 25 to 50 grammes of compressed yeast, or extracts equivalent to these amounts. Smaller quantities, of course, would be needed to make good a partial deficiency.

CERII OXALAS

(Cer. Oxal.)

Cerium Oxalate

Cerium oxalate is obtained as a by-product in the separation of thorium from monazite. It consists chiefly of cerium, lanthanum, praseodymium and neodymium oxalates, with smaller quantities of other rare earths; cerium or cerous oxalate, $\text{Ce}_2(\text{C}_2\text{O}_4)_3 \cdot 10\text{H}_2\text{O}$ -- 724.4, is usually present to the extent of about 50 per cent. It occurs as a white or slightly pink, granular, odourless and tasteless powder. When boiled with potassium hydroxide solution, white insoluble cerium hydroxides are produced, and the filtrate, acidified with acetic acid, produces a white precipitate on the addition of calcium chloride solution. On the addition of 2 millilitres of potassium sulphate solution to a solution of 0.1 gramme of cerium oxalate in 1 millilitre of sulphuric acid, a deposit of small, colourless crystals of double sulphates of potassium and rare earth elements is produced after some time.

Insoluble in water; soluble in diluted sulphuric and hydrochloric acids.

Standard.—Cerium oxalate yields on ignition not less than 47 per cent. of a reddish-brown residue. Arsenic limit, 5 parts per million.

Action and Uses.—Cerium oxalate has been used in cases of chronic vomiting, especially the vomiting of pregnancy. Its action is mechanical and resembles that of the salts of bismuth. It has been given with bismuth for the treatment of gastric ulcer and other inflammatory conditions of the stomach. It may be **administered** in powders or cachets, but should not be given in pills.

Dose.—0·12 to 0·6 gramme (2 to 10 grains).

CETACEUM

(Cetac.)

Spermaceti

Spermaceti is a solid wax obtained from the head of the sperm whale, *Physeter macrocephalus* Linn. (Fam. Physeteridæ), the bottle-nosed whale, *Hyperoodon rostratus* Billberg (Fam. Ziphiidæ) and possibly other species of *Physeter* which inhabit the Pacific, Atlantic and Indian Oceans. The sperm oil, found in a large cavity in the animal's head, deposits on standing a crystalline substance, which is separated by filtration, pressed, melted, purified from traces of oil with diluted sodium hydroxide solution and finally freed from the soap thus produced and from excess of alkali. Spermaceti occurs in translucent, crystalline, pearly-white masses, unctuous to the touch, with little odour or taste. Specific gravity, about 0·95. It may be powdered with the aid of a little alcohol or olive oil. It is readily inflammable and burns with a bright, somewhat sooty flame. The crystalline appearance of spermaceti, its solubility in boiling alcohol and its very low acidity are good indications of its purity. It consists chiefly of cetyl palmitate.

Insoluble in water and cold alcohol; soluble in ether, chloroform, carbon disulphide, fixed and volatile oils, and boiling alcohol (1 in 50).

Standard.—Spermaceti melts between 42° and 50°. Refractive index at 80°, about 1·4330. Acid value, not more than 1·0. Saponification value, 120 to 136. Iodine value, 3 to 4·4. It dissolves completely in 50 parts of boiling alcohol (absence of paraffin), the solution being neutral or not more than slightly acid to moistened litmus paper.

Action and Uses.—Spermaceti is a common ingredient of domestic cerates and cold creams, such as Unguentum Cetacei and Unguentum Aquæ Rosæ. An emulsion of spermaceti is occasionally prepared for internal use as a demulcent in the treatment of coughs; it is made by reducing the spermaceti to fine powder with a few drops of alcohol and emulsifying with yolk of egg or acacia.

Dose.—0·5 to 2 grammes (8 to 30 grains).

OLEUM CETACEI.—Sperm oil occurs as a thin, yellow liquid, almost free from odour when of good quality, but often having a slightly unpleasant, fishy odour. Specific gravity, about 0.88. Saponification value, 123 to 147. Iodine value, 79.5 to 84. It is soluble in all proportions of ether, chloroform or light petroleum and insoluble in dehydrated alcohol. It is used as a lubricating oil for machinery, and as a lamp oil.

Preparation

Unguentum Cetacei, B.P.C.—(Ung. Cetac.)—Spermaceti Ointment. Spermaceti 20 per cent., in white beeswax and liquid paraffin.

This ointment was included in the British Pharmacopæia, 1914.

CETRARIA

(Cetrar.)

Iceland Moss

Iceland moss consists of the dried lichen, *Cetraria islandica* (Linn.) Ach. (Fam. Parmeliaceæ), a plant which is indigenous to Great Britain and widely distributed over the Northern Hemisphere. It should be **stored** in a dry place.

The thallus is thin, foliose and cartilaginous, branching fanlike into curled or flattened lobes about 6 millimetres broad and fringed with small outgrowths terminating in pycnidia. It is greenish or greenish-brown above, greyish below and marked with numerous small, white, depressed spots. Occasional apothecia are present and appear as oval, reddish-brown spots, about 5 millimetres by 4 millimetres, near the margin of the thallus. A 5 per cent. decoction gelatinises on cooling and the product is stained blue by iodine. It is odourless and the taste is mucilaginous and bitter.

Iceland moss **contains** the carbohydrate, lichenin, which is accompanied by its isomeride, *isolichenin*. Lichenin is soluble in hot water, but the solution gelatinises as it cools; *isolichenin* is soluble in cold water and resembles a soluble modification of starch, but is possibly itself a mixture. Both lichenin and *isolichenin* are converted into dextrose by boiling with dilute mineral acid. Iceland moss also contains a crystalline bitter principle, fumaroprotocetraric acid, which is easily hydrolysed, giving fumaric and cetraric acids and the tasteless proto- α -lichesteric (lichenostearic) acid. The bitterness of the lichen can be removed by prolonged maceration with water, or by macerating the powder in a dilute solution of an alkali carbonate.

Standard.—Iceland moss contains not more than 2 per cent. of pine leaves and moss, and not more than 3 per cent. of other foreign organic matter.

Action and Uses.—Iceland moss is administered chiefly as decoction (Decoctum Cetrariæ, 1 in 20; dose, 1 to 4 fluid ounces) for its demulcent properties, and in the form of jujubes, the bitter cetraric acid being removed. In the northern countries of Europe it is used

as a food, either made into bread or boiled with milk, the bitterness being to some extent removed by previous washing with water. The decoction made with milk forms a nutritious and demulcent drink.

CEVADILLA

(Cevadill.)

Sabadilla

Synonym.--Caustic Barley.

Sabadilla consists of the dried, ripe seeds of *Schænocaulon officinale* A. Gray (Fam. Liliaceæ), a tall, herbaceous plant growing on the lower mountain slopes of the Eastern coast of Mexico, in Guatemala and in Venezuela. The seeds are freed from the papery pericarp.

The seeds are dark brown in colour, glossy and finely wrinkled, about 6 millimetres long and very narrow. They are slightly curved, acutely pointed at one extremity and more obtuse at the other where both hilum and micropyle are situated, although these are not easily discerned. A longitudinal depression with acute edges is usually visible on one side, due to the mutual pressure of the seeds upon one another in the fruit. The seeds are odourless and have an unpleasant, bitter taste; the powder is a powerful sternutatory.

The diagnostic **microscopical** characters are the radially elongated cells of the epidermis of the seed coat, the outer walls of which are considerably thickened and deep brown in colour; the polygonal cells of the endosperm, with colourless, thick and beaded walls, and containing a granular, nitrogenous substance and fixed oil.

Sabadilla **contains** several alkaloids, of which cevadine (crystalline veratrine) is the most important. Cevadine, $C_{32}H_{49}O_9N$, occurs in colourless crystals, melting at 205° , which have a very powerful sternutatory effect; it is easily hydrolysed by alkalis, yielding cevine (sabadinine) and cevadic (tiglic, methylcrotonic) acid. Cevadine is accompanied by the alkaloids veratridine, cevadilline and sabadine. The seeds also contain cevadic, veratric and chelidonic acids, fatty oil, resin, etc. Veratridine is amorphous and yields by hydrolysis veratric acid and verine (veratroine); like cevadine it has a powerful sternutatory effect. Much confusion has existed in the nomenclature of the alkaloids of sabadilla. The crystalline alkaloid, cevadine, has been termed veratrine; the amorphous alkaloid, veratridine, has also been termed veratrine, and the name has also been given to an indefinite mixture of cevadine and veratridine. Hence it is advisable to discard the name veratrine for any particular alkaloid and to reserve it for the total alkaloids of sabadilla. The identity of another alkaloid, sabadilline, is not clear.

Standard.—Sabadilla contains not more than 4 per cent. of foreign organic matter.

Sabadilla, in powder (Pulvis Cevadillæ: Pulv. Cevadill.), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—Sabadilla in powder and in the form of Acetum Cevadillæ (1 in 10), or as an ointment (1 in 4), has been used as a parasiticide, especially for pediculi capitis.

CHENOPODIUM

(Chenopod.)

Chenopodium

Synonym—American Wormseed.

Chenopodium consists of the fruit of *Chenopodium ambrosioides* var. *anthelminticum* A. Gray (Fam. Chenopodiaceæ), an annual or perennial plant abundant in the Southern United States and Central America. The fruit is collected in the autumn.

The fruits are small and subglobular, each surrounded by the five-partite perianth, from 0.7 to 1.0 millimetre in diameter, very light, and dull greenish-yellow or brownish in colour. The odour is strong, peculiar, and recalls that of eucalyptus, and the taste is pungent and bitter. On gently rubbing the fruit, the perianth and membranous pericarp are removed, exposing a single, shining, black, lenticular seed about 0.5 to 0.9 millimetre in diameter, containing a strongly curved embryo and a scanty endosperm. The fruits occasionally occur in small groups attached to short pieces of stem.

Chenopodium **contains** about 1 per cent. of volatile oil, which consists mainly of ascaridole and is contained in the glandular hairs of the pericarp.

Substitutes.—*Chenopodium ambrosioides* Linn., an annual plant widely distributed throughout the United States, is known as Mexican Tea. It bears a fruit similar to that of *C. ambrosioides* var. *anthelminticum*, but both the fruits and the volatile oil obtained from them have a less aromatic odour.

Standard.—Chenopodium contains not more than 2 per cent. of stalks and other foreign organic matter. Acid-insoluble ash, not more than 1.5 per cent.

Chenopodium, in powder (Pulvis Chenopodii: Pulv. Chenopod.), complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Chenopodium is a vermifuge used to expel round-worms and hook-worms. It is **administered** in the form of powder, but the volatile oil, Oleum Chenopodii, is now generally preferred. It should be taken at bedtime, **fasting**, and followed by a purgative.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

CHIMAPHILA

(Chimaphil.)

Chimaphila*Synonyms*—Chimaphila Leaves; Pipsissewa.

Chimaphila consists of the dried leaves of *Chimaphila umbellata* Nutt. (Fam. Pyrolaceæ), a small, evergreen plant indigenous to the northern latitudes of Europe, America and Asia.

The leaves are simple and shortly petiolate, the lamina oblanceolate, about 2·5 to 8 centimetres long, 0·8 to 1·8 centimetres broad, and entire. The apex is acute or slightly obtuse, the margin distantly serrate in the apical half and almost entire in the basal half; the texture is coriaceous, the surface smooth and the venation pinnate, the veins being prominent on the under surface. It has a slight odour and an astringent, bitter taste.

The diagnostic **microscopical** characters are the epidermal cells with wavy, moderately thickened walls, the broadly elliptical stomata in the lower epidermis only and the cluster-crystals of calcium oxalate.

Chimaphila is said to **contain** various crystalline constituents, to one of which the name chimaphilin has been applied. It is described as occurring in yellow needles melting at 113° to 114°, and having a composition corresponding to the formula, $C_{24}H_{21}O_4$. Arbutin is also said to be present, together with resin, gum, starch, tannic acid, sugar, etc.

Standard.—Chimaphila contains not more than 5 per cent. of stems or other foreign organic matter.

Action and Uses.—Chimaphila is employed as a diuretic in cardiac and renal disease. It is **administered** in the form of liquid extract (1 in 1) or may be made into a syrup by mixing one part of the liquid extract with three parts of syrup.

Dose. 1 to 3 grammes (15 to 45 grains).

CHIRATA

(Chirat.)

Chiretta*Synonym* —Chirayta.

Chiretta is the dried plant *Svertia Chirāta* Buch.-Ham. (Fam. Gentianaceæ), an erect, annual herb indigenous to the mountainous districts of Northern India. It is collected when in flower, dried and packed into bundles, about a metre long, which are often compressed before exportation.

The stem, which forms the major part of the drug, measures up to about 1 metre in length and 6 millimetres in diameter; it is purplish-brown, glabrous, slightly winged, much branched above, and has a narrow wood enclosing a large, continuous, easily separable, yellow

pith. The branches are slender, opposite and decussate, and bear numerous fruits, some flowers and a few leaves. The fruits are superior, ovoid and pointed, bicarpellary, unilocular, and contain numerous minute reticulated seeds. The flowers are small and paniced, the leaves opposite, sessile, ovate or lanceolate, with five to seven prominent, curving, lateral veins, and glabrous; the root is small and always oblique, attaining 10 centimetres in length and 12 millimetres in diameter at the crown. The drug is odourless and the taste intensely bitter.

Chiretta **contains** two amorphous bitter principles, chiratin and ophelic acid. The former is soluble in warm water, alcohol and ether, and when boiled with hydrochloric acid yields ophelic acid and chirato-genin. Chiretta yields to alcohol (60 per cent.) about 10 to 15 per cent. of extractive.

Substitutes.—Various other species of *Suertia* (e.g. *S. angustifolia* Buch.-Ham.; *S. alata* Royle; *S. trichotoma* Wall.) have been found mixed with or substituted for chiretta. From these the genuine drug may easily be distinguished by its dark colour, intensely bitter taste and continuous pith. *Andrographis paniculata* Nees (q.v.) can be distinguished easily by its less bitter taste, its green colour, numerous erect, slender, opposite branches and lanceolate, green leaves. The roots of *Rubia cordifolia* Linn. are also occasionally present: they are readily distinguished by their purple colour. Japanese chiretta, from *S. chinensis* Franchet, is a much smaller plant, varying from 10 to 35 centimetres in length and with a stem 1 to 2 millimetres thick; it is more bitter than *S. Chinata*.

Standard.—Chiretta contains not more than 5 per cent. of foreign organic matter. Acid-insoluble ash, not more than 1 per cent.

Chiretta in powder (Pulvis Chiratae: Pulv. Chirat.), contains the constituents and possesses the diagnostic characters of Chirata, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Chiretta owes its action to its bitterness. It is used in dyspepsia to improve the appetite, and is usually **administered** in the form of infusion or tincture. The preparations of chiretta do not contain tannin and may, therefore, be prescribed with iron.

Dose.—0.3 to 2 grammes (5 to 30 grains).

ANDROGRAPHIS.—*Andrographis* (Crete, Karyat; Kroat) is the entire dried plant, *Andrographis paniculata* Nees (Fam. Acanthaceae), an annual plant indigenous to India, Ceylon and Java. The stem, which is dark green in colour, is from 0.3 to 1 metre in height, attaining a diameter of about 3 to 6 millimetres; it is quadrangular, with longitudinal furrows, and slightly enlarged at the nodes. The leaves are opposite and decussate, lanceolate, up to about 8 centimetres long and 2.5 centimetres broad. The root is simple, woody and fusiform, and the small flowers and fruits are present. The drug is odourless and the taste is intensely bitter. The chief constituents are two non-nitrogenous, bitter principles, one of which is crystalline. It is used in India and the Eastern Colonies as an equivalent of chiretta. It owes its action to the presence of a bitter principle, the properties of which are similar to those of gentian root.

Preparations

Infusum Chiratae Concentratum, B.P.C.—(Inf. Chirat. Conc.)—Concentrated Infusion of Chiretta. 1 in 2½. This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh infusion of chiretta, and differs also in containing a small proportion of alcohol. Dose: 2 to 4 millilitres (½ to 1 fluid drachm).

Infusum Chiratae Recens, B.P.C.—(Inf. Chirat. Rec.)—Fresh Infusion of Chiretta, 1 in 20. When infusion of chiretta or Infusum Chiratae is prescribed, fresh infusion not being specified, either Infusum Chiratae Recens, or Infusum Chiratae Concentratum suitably diluted, may be dispensed. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

This infusion was included in the British Pharmacopoeia, 1914, under the name of Infusum Chiratae.

Tinctura Chiratae, B.P.C.—(Tinct. Chirat.)—Tincture of Chiretta. 1 in 10. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopoeia, 1914.

CHLORALFORMAMIDUM

(Chloralformam.)

Chloral Formamide

Synonym—Chloralamide.

Chloral formamide, $\text{CCl}_3 \cdot \text{CH}(\text{OH}) \cdot \text{NH} \cdot \text{CHO}$, may be prepared by gently heating chloral and formamide in molecular proportions. It sets, on cooling, to a solid mass and may be purified by recrystallising from water or 30 per cent. alcohol, avoiding heating above 55° . It occurs in colourless, lustrous, odourless crystals, with a somewhat bitter taste. It hydrolyses in aqueous solution at 60° yielding chloral hydrate and formamide. It is unaffected by dilute acids, but decomposes when warmed with sodium hydroxide solution, chloroform separating and ammonia and sodium formate being produced.

Soluble in water (1 in 21), alcohol (1 in 2); readily soluble in ether, acetone and ethyl acetate; slowly soluble in glycerin (1 in 12).

Standard.—Chloral formamide melts between 114° and 115° . It volatilises without the evolution of inflammable vapours (absence of certain organic impurities) and leaves not more than 0.01 per cent. of residue. 1 gramme dissolved in 25 millilitres of water yields a solution which is neutral to litmus and does not become turbid immediately on the addition of silver nitrate solution (limit of chloride).

Action and Uses.—Chloral formamide is a hypnotic, slower in action and safe than chloral, since it has not the same depressant action on the heart. It appears to be absorbed more slowly than chloral hydrate, and after absorption is converted into chloral and excreted partly as urochloralic acid. It is very slowly excreted and repeated doses lead to cumulation; when the stored drug reaches a certain amount, it appears to be set free suddenly in the circulation, causing symptoms of acute poisoning with collapse. It is especially useful in the insomnia of cardiac disease and acute alcoholism.

Chloral formamide may be **administered** in solution made by dissolving 1 part of chloral formamide in $2\frac{1}{2}$ parts of alcohol, diluting

with water to 30 parts and flavouring with orange or liquorice; hot water must not be used. When the proportion soluble in water is exceeded and alcohol is undesirable, the finely powdered chloral formamide may be suspended with mucilage of acacia. If prescribed in powder form, with or without potassium bromide, the powders should be covered with tin foil. Chloral formamide is a common ingredient, with potassium bromide, of remedies for sea-sickness. It is **incompatible** with alkalis and should not be given in hot liquids.

Dose.— 1 to 3 grammes (15 to 45 grains).

CHLORALIS HYDRAS

(Chloral. Hydr.)

Chloral Hydrate

Chloral hydrate, or trichloroethyleneglycol, $\text{CCl}_3\cdot\text{CH}(\text{OH})_2$, is obtained by the combination of water with anhydrous chloral which may be prepared by the action of dry chlorine on ethyl alcohol. The product is crystallised from water and purified by recrystallisation from chloroform or other solvent. It occurs in colourless, transparent, non-deliquescent crystals with a pungent, but not acrid, odour and a pungent, somewhat bitter taste. It volatilises slowly on exposure to air. When heated, chloral hydrate liquefies between 50° and 58° . The aqueous solution is neutral or only slightly acid to litmus and when mixed with sodium hydroxide solution, chloroform is produced. Chloral hydrate forms a liquid mixture when triturated with many organic compounds such as camphor, menthol, thymol, phenol and phenazone.

Soluble in water (4 in 1), alcohol (90 per cent.) (5 in 1), chloroform (1 in 3), ether (2 in 1) and fixed and volatile oils.

Standard, B.P.—Chloral hydrate contains not less than 99 per cent. of $\text{C}_2\text{H}_3\text{O}_2\text{Cl}_3$. Ash, not more than 0.05 per cent. It complies also with tests for the absence of certain organic impurities, chloral alcoholate, and chloride.

Action and Uses.—Chloral hydrate is a hypnotic. It is rapidly absorbed from the stomach and may produce its effects within a few minutes. In small doses it induces a condition closely resembling natural sleep, from which the patient can easily be awakened by ordinary means. Such sleep usually lasts from six to eight hours, and after-effects from the drug are not usually experienced, though headache and giddiness may result. Chloral hydrate depresses the central nervous system, dulling the sensory and motor functions of the brain and spinal cord. It has not the analgesic and anodyne action of morphine, and acute pain may prevent the production of sleep by chloral hydrate. It is of

special value as a hypnotic in simple nervous insomnia, in puerperal mania, insanity and delirium tremens. Chloral hydrate and concentrated solutions of chloral hydrate blister the skin; as a vesicant it may be applied spread on adhesive plaster. A mixture with camphor is applied to the skin for its local anodyne properties.

Chloral hydrate is usually **administered** in dilute solution as syrup of chloral or in combination with potassium bromide. It should not be taken in the form of tablets or pills since these concentrated forms may damage the mucous membrane of the mouth and alimentary tract. It is a powerful deodorising, antiseptic and preservative agent. Spray solutions (2 per cent.) may be used in tonsillitis. It is sometimes used in hair washes for its antiseptic properties, in the proportion of 2 grains to 1 fluid ounce. Chloral hydrate is excreted in the urine in combination with glycuronic acid and sulphuric acid. These excretion products may be present in sufficient concentration to reduce Fehling's solution.

The toxic effects of larger doses of chloral hydrate are shown by a fall in temperature and blood pressure, with a slow and feeble respiration. In cases of **poisoning**, the stomach should be emptied and washed out with water at 105°F., the patient being kept warm. Strychnine and caffeine should be given and artificial respiration used, if necessary. Chloral hydrate is **incompatible** with alkalis, alkaline earths and alkali carbonates.

Dose. 0.3 to 1.2 grammes (5 to 20 grains).

GLUCOCHLORAL.—Glucochloral, $C_8H_{11}O_6Cl_3$, occurs as fine, colourless, acicular crystals, having a bitter and nauseous taste. Melting-point, 185°; it volatilises without decomposition. It is soluble in water (1 in 170), freely soluble in hot water and alcohol. Glucochloral is a hypnotic and sedative for use in simple insomnia. It should be used with care, since its effects are uncertain, and symptoms of poisoning have followed a dose of 0.5 gramme (8 grains). In cases of poisoning by glucochloral, the antidotes recommended under chloral hydrate should be employed. Dose—0.2 to 0.6 gramme (3 to 10 grains).

Preparations

Chloral Camphoratum, B.P.C.—(Chloral Camph.)—Camphorated Chloral. *Syn.*—Chloral cum Camphora. The liquid obtained by mixing equal weights of chloral hydrate and camphor.

Liquor Bromidi Compositus, B.P.C.—(Liq. Brom. Co.)—Compound Bromide Solution. *Syn.*—Liquor Bromochloral Compositus. Each fluid drachm contains 15 grains of chloral hydrate and 15 grains of potassium bromide, with extract of cannabis, liquid extract of hyoscyamus, tincture of orange, glycerin and distilled water. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Pigmentum Chloralis et Camphoræ Compositum, B.P.C.—(Pig Chloral. et Camph. Co.)—Compound Chloral and Camphor Paint. Equal weights of chloral hydrate, camphor and phenol.

Syrupus Chloralis, B.P.C.—(Syr. Chloral.)—Syrup of Chloral. Chloral hydrate, 1 in 5, in distilled water and syrup; each fluid drachm contains about 11 grains of chloral hydrate. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

This syrup was included in the British Pharmacopœia, 1914, under the name of Syrupus Chloral.

Syrupus chlorali hydrati I.A. contains 5 per cent. of chloral hydrate.

CHLORAMINA

(Chloram.)

Chloramine*Synonym*—Chloramine-T.

Chloramine is sodium *p*-toluenesulphonchloroamide, $\text{ClI}_3 \cdot \text{C}_6\text{H}_4 \cdot \text{SO}_2\text{Na} : \text{NCl}, 3\text{H}_2\text{O}$, and may be prepared by the limited interaction of *p*-toluenesulphonamide with a cold 5 per cent. alkaline solution of sodium hypochlorite, filtering and adding saturated sodium chloride solution. The crystals which separate are collected, washed with brine and dried in air. Chloramine occurs as white crystals or as a crystalline powder with a faint odour of chlorine and an unpleasant, bitter taste. On exposure to air, chloramine effloresces and decomposes slowly, giving off chlorine and acquiring a yellow colour; it is decomposed slowly by alcohol (95 per cent.). Heated at 100° , it becomes anhydrous without undergoing decomposition; on ignition, decomposition occurs suddenly and a residue containing sodium sulphate remains. The aqueous solution has a slightly alkaline reaction; on the addition of an acid, a white precipitate is produced which redissolves when the mixture is again rendered alkaline. On the addition of chloramine to a solution of potassium iodide, iodine is liberated. Chloramine may be distinguished from dichloramine by the fact that it does not liberate bromine from sodium bromide solution until the mixture is acidified. Chloramine should be **stored** in well-closed glass containers, protected from light and in a cool place.

Soluble in water (about 1 in 7), boiling water (1 in 2) and alcohol (90 per cent.) (1 in 12); insoluble in ether, chloroform and benzene.

Standard, B.P.—Chloramine contains not less than 98 per cent. and not more than the equivalent of 103 per cent. of $\text{C}_7\text{H}_7\text{O}_2\text{NCISNa}, 3\text{H}_2\text{O}$. It complies also with limit tests for readily carbonisable substances, the corresponding *ortho* compound and sodium chloride.

Action and Uses.—Chloramine is a powerful antiseptic and is sometimes used to replace a solution of hypochlorites in the irrigation of wounds by the Carrel-Dakin method and, being nearly neutral and less irritant, is sometimes preferred. For this purpose a 2 per cent. solution is suitable. As a mouth-wash or as an injection for the bladder or urethra, a 0.5 per cent. solution may be used. Chloramine has no special solvent action on necrosed tissue. Aqueous solutions of chloramine are comparatively stable and may be kept for a considerable period without undergoing decomposition.

HALAZONE.—Halazone is *p*-sulphondichloroamidobenzoic acid, $\text{C}_6\text{H}_4(\text{SO}_2\text{NCl})\text{COOH}$, a white powder with a strong odour of chlorine. A mixture with sodium carbonate is sometimes used for the sterilisation of water in the proportion of 0.004 to 0.008 gramme to 1 litre of water.

Preparation

Carbasus Chloraminæ, B.P.C.—(Carbas. Chloram)—Chloramine Gauze. It contains from 4 to 6 per cent. of chloramine

CHLORBUTOL

(Chlorbutol)

Chlorbutol

Chlorbutol is trichloro-*tert.*-butyl alcohol, $(\text{CH}_3)_2\text{C}(\text{CCl}_3)\text{OH}$, with a variable amount of water of crystallisation, and may be prepared by heating a mixture of acetone and chloroform with potassium hydroxide. It occurs in colourless crystals with a characteristic musty and somewhat camphoraceous odour and taste. It volatilises at ordinary temperatures. When anhydrous, it melts at 96° ; the boiling-point is about 167° . When solution of iodine is added to an aqueous solution of chlorbutol rendered alkaline by means of dilute sodium hydroxide solution, iodoform is produced. When chlorbutol is warmed with aniline and potassium hydroxide solution, the odour of phenyl isocyanide is produced. It should be **stored** in well-closed containers.

Soluble in water (1 in 125), alcohol (90 per cent.) (1 in 1), ether, chloroform, glycerin (1 in 10) and volatile oils.

Standard, B.P.—Chlorbutol has a melting-point not below 78° . Ash, not more than 0.1 per cent. It complies with a test for acidity and with a limit test for chloride.

Action and Uses.—Chlorbutol is sedative, analgesic and antiseptic. As a hypnotic, it is not of much value since its dose for this purpose is near the amount liable to cause toxic symptoms. Its sedative properties are especially exerted upon the stomach, and it is used in sea-sickness and to allay post-operative vomiting. It is useful in the treatment of chorea. An enema of 1.2 grammes (20 grains) of chlorbutol dissolved in glycerin or olive oil is useful for controlling the muscular spasms in tetanus. It resembles chloral in most respects, but is less depressing to the heart and not so irritating to mucous membranes. Like chloral formamide its action is cumulative. Chlorbutol, in small doses, causes insensitiveness of the bladder, resulting in some cases in retention of urine; this property makes it of service for controlling frequent micturition. A saturated solution in water with the addition of *Liquor Adrenalinæ Hydrochloridi* (2 fluid drachms to each ounce of solution) is employed in conjunctivitis due to irritant gases. As an antispasmodic, chlorbutol is employed in acute gastric flatulence, persistent hiccough, or the severe pain of shingles. A saturated aqueous solution, in doses equivalent to 0.06 gramme (1 grain) three or four times a day, is employed to relieve the paroxysms of whooping cough. **Externally**, chlorbutol is employed to relieve pruritus and the irritation of chronic skin diseases. A solution in liquid paraffin, inhaled as a spray from an atomiser, is used as an antiseptic and analgesic to relieve catarrh.

Chlorbutol may be **administered** in powders, which should be dispensed in a bottle if they are to be kept for any length of time. Tablets of chlorbutol are not readily soluble, and it should be given preferably in gelatin capsules. Chlorbutol may be suspended in mixtures with acacia or

tragacanth, or an elixir may be prepared containing 0.6 gramme (10 grains) of chlorbutol in 4 millilitres (1 fluid drachm) each of alcohol (or compound tincture of cardamom or tincture of orange) and glycerin. It may be dissolved in ten times its weight of olive oil or liquid paraffin and the solution emulsified. Chlorbutol is used as a preservative of solutions for hypodermic injection.

Dose.—0.3 to 1.2 grammes (5 to 20 grains).

CHLOROFORMUM

(Chlorof.)

Chloroform

Chloroform is trichloromethane to which from 1 to 2 per cent. by volume of dehydrated alcohol has been added. It may be prepared by the action of chlorinated lime, slaked lime and water on acetone, ethyl alcohol, or industrial methylated spirit and subsequent purification. It occurs as a colourless, heavy, volatile liquid with a characteristic odour and a sweet, burning taste. It is non-inflammable, but the strongly heated vapour may be ignited; it burns with a green flame with production of noxious vapours. On exposure to air and light, pure chloroform is gradually oxidised, becoming contaminated with the very poisonous carbonyl chloride (phosgene) and with chlorine. In the medicinal grade of chloroform this decomposition is greatly retarded by the addition of the small percentage of alcohol; the alcohol serves also to decompose any carbonyl chloride that may be formed. When warmed with a trace of aniline and sodium hydroxide solution, the odour of phenyl isocyanide is produced. Chloroform should be **stored** in well-closed, glass-stoppered bottles, protected from light.

Soluble in water (1 in 200); miscible in all proportions with dehydrated alcohol, ether, fixed and volatile oils and most organic solvents.

Standard, B.P.—Chloroform has a specific gravity of 1.485 to 1.490. On distillation, a portion, usually not more than 15 per cent. v/v, distils below 60°, the remainder distilling between 60° and 62°. Residue on evaporation, not more than 0.004 per cent. w/v. No foreign odour is detectable during the evaporation of 10 millilitres on filter paper. It complies also with limit tests for acidity, chloride, free chlorine, hydrochloric acid, foreign organic matter, foreign chlorine compounds, decomposition products and aldehyde.

Action and Uses.—Chloroform is the best known member of the group of drugs classed as general anæsthetics. When inhaled, it produces a feeling of warmth in the throat, which is followed by relaxation and, finally, unconsciousness. For anæsthesia by inhalation, chloroform should not exceed about 1 per cent. of the inspired air. Chloroform should

not be given to diabetics, nor to patients with heart or kidney disease, nor to those suffering from shock. It is unsuitable in the presence of sepsis, but is valuable in operations on the upper abdomen since the respiratory exertions are less marked than under ether anæsthesia. The great danger of chloroform inhalation is in the sudden absorption of a large dose during the early stages of administration. This either excites the medulla and the heart ceases to beat as the result of vagal inhibition, or the ventricles fibrillate, possibly as a result of sympathetic stimulation. Treatment of this condition should consist of artificial respiration, inhalation of carbon dioxide, the injection of atropine in normal saline solution directly into a vein, the intravenous injection of adrenaline (1 in 100,000) or pituitary (posterior lobe) extract well diluted and cardiac tonics, as well as the more usual means adopted for rousing the activity of the heart. In the third stage of chloroform narcosis, depression of the heart muscle results from the direct toxic action of the drug. This condition is improved by stopping the administration for a time. Unfortunately all statistics of deaths occurring during anæsthesia agree in showing that chloroform is more dangerous than any other commonly used anæsthetic.

The advantages of chloroform over ether are its more agreeable odour and its rapidity of action; it is less likely to set up irritation of the respiratory passages or to cause nausea and vomiting. After prolonged anæsthesia, especially in delicate subjects and children, a condition known as delayed chloroform poisoning may occur. The symptoms are first observed from one to four days after the administration of the anæsthetic, and consist of vomiting, delirium and coma, with the appearance of acetone bodies in the urine. The pathology and general condition is very similar to that seen after poisoning by the organic preparations of arsenic. This condition is unlikely to occur when the patient has been kept on a rich carbohydrate diet and if dextrose is given shortly before the administration of the anæsthetic. A.C.E. Mixture (Vapor Chloroformi Compositus) contains dehydrated alcohol, 1 part, chloroform, 2 parts, and ether, 3 parts (by volume), and is a safer anæsthetic than pure chloroform when deep and prolonged anæsthesia is required. C.E. Mixture (Vapor Chloroformi et Ætheris) contains chloroform, 1 part, and ether, 3 parts (by weight).

Administered by the mouth, chloroform causes a sensation of warmth in the stomach and is a useful carminative in gastric flatulence and pain. Glass capsules or ampoules of chloroform, containing 0.6 millilitre (10 minims) or more, enclosed in absorbent material, are broken and the vapour inhaled for the relief of asthma. Similar capsules containing 20 minims are used for the production of analgesia during childbirth. As flavouring and preservative agents, stimulants and carminatives, Aqua Chloroformi, Emulsio Chloroformi, Spiritus Chloroformi, and Tinctura Chloroformi Composita are in constant use. Perles or capsules for internal use contain usually 0.2 millilitre (3 minims) of chloroform. **Externally**, chloroform is rubefacient. It is applied over neuralgic areas, and in gout, lumbago and rheumatism,

often with menthol, belladonna, or aconite. Linimentum Chloroformi is a counter-irritant; Chloroformum Camphoratum is used for tooth-ache. Chloroform is a useful preservative for aqueous preparations of vegetable and animal extracts, one minim in each fluid ounce being a suitable proportion. It is also used as a solvent for resins, alkaloids, fats, fixed and volatile oils, gutta percha and rubber. In cases of **poisoning** by swallowing chloroform, the stomach pump should be used, or an emetic administered, followed by large draughts of water containing sodium carbonate in solution and the injection of strong hot coffee into the rectum.

Dose.—0.06 to 0.3 millilitre (1 to 5 minims).

Preparations

Aqua Chloroformi, B.P.—(Aq. Chlorof.)—Chloroform Water. Chloroform, 1 in 400, in distilled water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Aqua Chloroformi Concentrata, B.P.C.—(Aq. Chlorof. Conc.)—Concentrated Chloroform Water. Chloroform, 1 in 10. One part added to 39 parts of distilled water yields a preparation which is equivalent in strength to chloroform water, but contains 1.5 per cent. v/v of alcohol (90 per cent.). Dose.—0.4 to 0.8 millilitre (6 to 12 minims).

Aqua Chloroformi Duplex, B.P.C.—(Aq. Chlorof. Dup.)—Double Chloroform Water. *Syn.*—Aqua Chloroformi Fortior; Stronger Chloroform Water. Chloroform, 1 in 200, in distilled water. Dose.—8 to 16 millilitres (2 to 4 fluid drachms).

Chloroformum Camphoratum, B.P.C.—(Chlorof. Camph.)—Camphorated Chloroform. *Syn.*—Chloroform of Camphor. Camphor, 2 parts by weight, dissolved in chloroform, 1 part by volume.

Emulsio Chloroformi, B.P.C.—(Emuls. Chlorof.)—Emulsion of Chloroform. Chloroform, 1 in 20, with tincture of quillaia, mucilage of tragacanth and distilled water. Dose.—0.3 to 2 millilitres (5 to 30 minims).

Linimentum Aconiti Oleosum, B.P.C.—(Lin. Aconit. Oleos.)—Liniment of Aconite with Oil. *Syn.*—A.B.C. Liniment. Equal parts of liniments of aconite, belladonna and chloroform. (The non-oily liniment of the British Pharmaceutical Codex, 1923, is included under the name of Pigmentum Aconiti Compositum).

Linimentum Belladonnæ cum Chloroformo, B.P.C.—(Lin. Bellad. c. Chlorof.)—Liniment of Belladonna with Chloroform. Chloroform, 1 in 8, with liniment of belladonna.

Linimentum Chloroformi, B.P.C.—(Lin. Chlorof.)—Liniment of Chloroform. Chloroform and liniment of camphor, equal parts.

This liniment was included in the British Pharmacopæia, 1914.

Spiritus Chloroformi, B.P.—(Sp. Chlorof.)—Spirit of Chloroform. Chloroform, 5 per cent. v/v, in alcohol (90 per cent.). Dose.—0.3 to 2 millilitres (5 to 30 minims).

Tinctura Chloroformi Composita, B.P.C.—(Tinct. Chlorof. Co.)—Compound Tincture of Chloroform. Chloroform, 1 in 10, with alcohol (90 per cent.) and compound tincture of cardamom. Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

Tinctura Chloroformi et Morphine, B.P.C.—(Tinct. Chlorof. et Morph.)—Tincture of Chloroform and Morphine. *Syn.*—Chlorodyne; Tinct. Chlorof. et Morph. B.P. '85. Chloroform, 1 in 8, and morphine hydrochloride, about 1 in 450, with ether, alcohol (90 per cent.), dilute hydrocyanic acid, about 1 in 16, oil of peppermint, liquid extract of liquorice, treacle and syrup. Dose.—0.3 to 0.6 millilitre (5 to 10 minims).

Tinctura Chloroformi et Morphine Composita, B.P.C.—(Tinct. Chlorof. et Morph. Co.)—Compound Tincture of Chloroform and Morphine. Chloroform, about 1 in 13, morphine hydrochloride, 1 in 100, with dilute hydrocyanic acid, about 1 in 20, tincture of capsicum, tincture of cannabis, oil of peppermint, glycerin and alcohol (90 per cent.) Dose.—0.3 to 1 millilitre (5 to 15 minims).

This tincture was included in the British Pharmacopœia, 1914.

CHLOROPHYLLUM

(Chlorophyll.)

Chlorophyll

Chlorophyll is the green colouring matter of the leaves and green parts of plants. It is an amorphous organic compound consisting of an ester-like combination of phytol and methyl alcohol with a complex tricarboxylic acid containing magnesium. By the action of acids the magnesium is replaced by hydrogen and a brownish, amorphous product, termed pheophytin, is obtained. Both natural chlorophyll and pheophytin are used medicinally. They are distinguished from the commercial derivatives, which are used as colouring matters and in which the magnesium is replaced by copper or zinc, by the absence of these metals and by the intense fire-red fluorescence which they give in ultra-violet light even in very dilute solution. For non-medicinal or technical purposes, chlorophyll derivatives are prepared by extraction from nettles spinach and other green plants in the presence of copper, removing yellow colouring matter and other impurities, and modifying the solubility of the product. Fat-soluble chlorophyll is prepared by diluting the purified extract with varying amounts of a suitable fat, the proportion depending on the strength of the colouring matter required. Alcohol-soluble chlorophyll is similarly obtained by diluting the extract with castor or other suitable oil. Water-soluble chlorophyll is obtained by the action of dilute alkalis on the purified extract.

Action and Uses.—Chlorophyll, when administered in large doses, is stated to possess blood-forming properties, particularly when given with iron. This action may be due to its having a somewhat similar chemical composition to that of hæmoglobin. It is employed principally for colouring fats, oils, soaps and other preparations.

CHONDRUS

(Chond.)

Chondrus

Synonyms—Carrageen; Irish Moss.

Chondrus consists of the dried seaweed, *Chondrus crispus* Stackhouse (Fam. Gigartinales), which is found on the northern shores of the Atlantic Ocean, but collected for medicinal purposes chiefly on the

northern shores of Brittany where it grows below low-water mark upon rocks and stones. It is green or purplish-brown when fresh, but is partly bleached by watering and exposing it to the sun, after which it is dried.

The drug occurs in yellowish, translucent, horny masses which consist of slender thalli varying from 5 to 30 centimetres in length, rounded at the base, but flattened in the upper part, and branching dichotomously, the ultimate branches having an emarginate or two-lobed apex. Here and there in the branches of the thallus are small oval patches or openings, which are the fructifications (cystocarps) or the places from which they have fallen. Microscopically the drug has a cellular structure, compact in the outer layers and filamentous axially; all the cell walls are composed of a form of cellulose.

The aqueous extract **contains** two colloidal substances which are considered to be mixtures of salts of sulphuric acid united to a carbohydrate-yielding complex. Carrageenin is the name given to the mixture of substances soluble in boiling water. The drug also contains about 7 per cent. of proteins and a little iodine. It yields about 25 to 40 per cent. of extractive to cold water and about 70 to 85 per cent. to boiling water.

Substitutes.—*Gigartina mamilliosa* Agardh. resembles chondrus, but can be distinguished by the numerous papillæ on the ultimate segments. It is said to possess similar properties.

Standard.—Chondrus contains not more than 2 per cent. of foreign organic matter.

Action and Uses.—Chondrus is used in the form of a decoction as a demulcent in the treatment of coughs. It is also employed as an emulsifying agent for cod-liver and other oils and as a substitute for gelatin in the preparation of jellies for invalids.

Preparation

Decoction 'Chondri, B.P.C.—(Dec. Chond.)—Decoction of Chondrus. *Syn.*—Decoction of Irish Moss; Mucilago Chondri; Mucilage of Irish Moss. 1 in 40. Dose.—30 to 120 millilitres (1 to 4 fluid ounces), or more.

CHROMII TRIOXIDUM

(Chrom. Triox.)

Chromium Trioxide

Synonyms—Acidum Chromicum; Chromic Acid; Chromic Anhydride.

Chromium trioxide may be prepared by adding sulphuric acid to an aqueous solution of potassium dichromate. It occurs in dark red, odourless, acicular crystals or in dark brown masses, and is very corrosive. On heating, it melts at about 192°, evolving oxygen at higher temperatures and forming at a red heat the insoluble, green chromium

sesquioxide, Cr_2O_3 . In contact with small amounts of organic matter such as alcohol (90 per cent.), ether, or glycerin, it is liable to sudden combustion or explosion. When warmed with hydrochloric acid, chlorine is evolved. On the addition of alkali hydroxides to the aqueous solution, the corresponding chromate is formed and the solution gives a yellow precipitate on the addition of a solution of lead acetate. On the addition of dilute sulphuric acid and solution of hydrogen peroxide to a dilute aqueous solution of chromium trioxide, the mixture acquires a blue colour; when ether is added and the mixture shaken, and allowed to stand, the ethereal layer has a blue colour. It should be **stored** in a well-closed, stoppered bottle.

Soluble in water (2 in 1) and ether.

Standard, B.P.—Chromium trioxide contains not less than 95 per cent. of CrO_3 . Water-soluble matter after ignition, not more than 2 per cent. It complies also with a limit test for sulphate.

Action and Uses.—Chromium trioxide is a powerful oxidising agent and caustic. It is not given internally, but is used to destroy granulations and excrescences and to wash out infected wounds. For the destruction of warts, superficial growths and indolent ulcerations, it is used in a concentrated aqueous solution (1 in 1) or as *Liquor Chromii Trioxidi*, applied with a glass rod, the surrounding tissues being protected if necessary by smearing with soft paraffin. Solutions (1 in 50 to 1 in 20) are used for affections of the tongue and mouth, as well as for application to the feet in hyperhidrosis and bromidrosis, while a 1 in 500 solution is used as a gargle. As a general lotion and injection for antiseptic purposes, a very weak solution (1 in 2000 or 4000) may be used.

Chromium trioxide is **incompatible** with most organic substances; it decomposes alcohol and glycerin with evolution of heat. Inhalation of air containing chromium trioxide, in the proportion of 1 milligram in 10 cubic metres (or less) of air, causes bleeding from the nose followed by perforation of the nasal septum. This occurs among workers in the chromium plating industry, where ulcers or "chrome holes" may appear also on the hands or other exposed parts of the body, but can, to a large extent, be prevented by the application of soft paraffin.

ACIDUM OSMICUM.—Osmic acid, OsO_4 , occurs as yellow crystals melting at about 40° ; boiling-point, below 100° . Its vapour is very irritating and extremely poisonous, attacking the eyes and lungs. It is decomposed by contact with organic substances and is used in 1 and 2 per cent. w/v solutions for hardening animal tissues prior to cutting sections and for staining fats in microscopical work. Its solution gives a purple colouration with tannic acid and other derivatives of pyrogallol.

Preparation

Liquor Chromii Trioxidi, B.P.C.—(*Liq. Chrom. Triox.*)—Solution of Chromium Trioxide. *Syn.*—*Liquor Acidi Chromici*. Chromium trioxide, 25 per cent. w/v, in distilled water.

This solution was included in the British Pharmacopæia, 1914, under the name of Liquor Acidi Chromici.

CHRYSAROBINUM

(Chrysarob.)

Chrysarobin

Chrysarobin is a mixture of substances obtained from araroba by extraction with hot benzene, the filtered solution being evaporated and the residue reduced to powder. It occurs as a light, micro-crystalline, yellow powder, without odour or taste. When heated, chrysarobin melts at about 155° to 165° , evolving yellowish fumes at higher temperatures. It is soluble in hot sodium hydroxide solution giving a dark, brownish-red solution which shows a green fluorescence when largely diluted with water. When chrysarobin is shaken with dilute solution of ammonia mixed with twice its volume of water, a pink colouration slowly develops and can be seen on filtering the mixture. An evanescent violet colouration is produced when a trace of chrysarobin is mixed with 1 drop of fuming nitric acid and 1 drop of dilute solution of ammonia added. Chrysarobin contains chrysophanolanthranol, $C_{15}H_{12}O_3$, the monomethyl ether of dihydroemodinanthranol, chrysophanol (chrysophanic acid), emodin monomethyl ether and other substances of analogous composition.

Almost **insoluble** in water; slightly soluble in alcohol (90 per cent.); soluble in hot chloroform, hot benzene, and in fats.

Standard, B.P.—Chrysarobin leaves not more than 0.5 per cent. of ash.

Action and Uses.—Chrysarobin has been given internally in psoriasis and some other chronic skin diseases, but since it is liable to give rise to gastro-enteritis it is now rarely employed. **Externally**, it is used in the treatment of psoriasis and ringworm of the scalp and glabrous skin. For this purpose *Pigmentum Chrysarobini* and *Unguentum Chrysarobini* are suitable preparations. The pigment has the advantage of not staining linen. The ointment should not be applied over a large area of skin and sometimes it is advisable to use it in a diluted form. Stains caused by chrysarobin may be readily removed by solution of chlorinated lime. Ointment of lead oleate has been suggested as a suitable base for the preparation of an ointment. When absorbed into the system, chrysarobin is excreted in the urine in the form of a yellow pigment which changes to red on the addition of an alkali.

Preparations

Pigmentum Chrysarobini, B.P.C.—(Pig. Chrysarob.)—Chrysarobin Paint. Chrysarobin, 1 in 10, in solution of gutta percha.

Unguentum Chrysarobini, B.P.—(Ung. Chrysarob.)—Ointment of Chrysarobin. *Syn.*—Chrysarobin Ointment. Chrysarobin, 4 per cent., in simple ointment.

Unguentum Chrysarobini Compositum, B.P.C.—(Ung. Chrysarob. Co.)—Compound Chrysarobin Ointment. Chrysarobin and ichthammol, of each 5 per cent., and salicylic acid, 2 per cent., in yellow soft paraffin.

CIMICIFUGA

(Cimicif.)

Cimicifuga

Synonyms—*Actææ Racemosæ Radix*; Black Snakeroot; Black Cohosh.

Cimicifuga consists of the dried rhizome and roots of *Cimicifuga racemosa* Nutt. (Fam. Ranunculaceæ) growing in Canada and the United States of America. It is collected in the autumn.

The drug is dark brown in colour and consists of a hard, horizontal, sub-cylindrical rhizome, about 1 to 2 centimetres in diameter and 5 to 15 centimetres long. It bears several stout, ascending branches which are marked with encircling leaf-scars, and terminate either in the remains of a bud or in a circular cup-shaped scar. To the under surface are attached stout, brittle roots, often broken off short, or represented by circular scars about 2 or 3 millimetres in diameter. The transversely cut surface of the rhizome shows a thin, dark, horny bark, separated by a distinct cambium line from the wood, which consists of a ring of numerous, thin, pale wedges, separated by broad, darker medullary rays, and the centre is occupied by a large dark pith; the cells of the bark, medullary rays and pith contain starch. The roots show from three to six paler wedges of wood united by their apices and separated by broad, darker medullary rays. The drug is without odour, but the taste is bitter and acid.

Cimicifuga **contains** a large amount of resin, *isoferulic* acid, a trace of salicylic acid, a phytosterol, palmitic acid, and three crystalline bodies which are apparently alcohols. It yields to alcohol (60 per cent.) about 22 per cent. of extractive. Cimicifugin is the name given to a resinous product obtained by pouring a strong tincture of cimicifuga into water.

Standard.—Cimicifuga contains not more than 2 per cent. of stems or other foreign organic matter. Acid-insoluble ash, not more than 4 per cent.

Cimicifuga, in powder (*Pulvis Cimicifugæ* : *Pulv. Cimicif.*), contains the constituents of Cimicifuga, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Cimicifuga is used as a bitter, and as a mild expectorant in bronchial catarrh. It has been given in chorea and rheumatic affections, in various forms of neuralgia and for its supposed action in various uterine disorders. It is **administered** in the form of a liquid extract (*Extractum Cimicifugæ Liquidum*, 1 in 1; dose, 5 to 30 minims) and also as the tincture.

Dose.—0.5 to 1 gramme (8 to 15 grains).

Preparation

Tinctura Cimicifugæ, B.P.C.—(*Tinct. Cimicif.*)—Tincture of Cimicifuga.
Syn.—Tincture of *Actææ Racemosa*. 1 in 10. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

CINCHONA

(Cinchon.)

Cinchona

Synonyms—*Cinchonæ Rubræ Cortex*; Red *Cinchona* Bark;
Jesuit's Bark; Peruvian Bark.

Cinchona is the dried bark of cultivated trees of *Cinchona Calisaya* Wedd., *C. Ledgeriana* Moens, *C. officinalis* Linn., *C. succirubra* Pav., or of hybrids of either of the last two species with either of the first two (Fam. Rubiaceæ). The numerous species of *Cinchona* are indigenous to South America; they are cultivated in Java, Ceylon, India, Tanganyika and other places, the bark being exported chiefly from Java. The methods most commonly used for the collection of cinchona are two, namely, "uprooting" and "coppicing." The bark is dried either in the sun or by artificial heat.

The stem bark occurs in quilled or curved pieces, of various sizes, up to 30 centimetres or more long, from about 1 to 8 centimetres in width or diameter and usually about 2 to 6 millimetres thick. The outer surface is dull brownish-grey or grey and frequently bears lichens and mosses; it is usually rough, being marked with transverse fissures, which vary in type according to the species and are often numerous, while longitudinally it is either furrowed or wrinkled and fissured; exfoliation of the outer bark occurs in some varieties. The inner surface is striated and varies in colour, according to the species, from pale yellowish-brown to deep reddish-brown. The fracture is short in the external layers and fibrous in the inner layers. The root bark occurs in pieces about 2 to 7 centimetres long, irregularly channelled, curved or twisted. Externally, the pieces show conchoidal depressions and are often scaly; the inner surface is more or less striated and of the same colour as the outer surface, both surfaces resembling in colour that of the inner surface of the stem bark; the fracture is fibrous. The drug has a slight, characteristic odour and an intensely bitter and somewhat astringent taste.

The diagnostic **microscopical** characters are the thin-walled cork cells; the numerous isolated, yellowish, spindle-shaped, striated phloem fibres up to 90 microns in diameter, with conspicuous, somewhat funnel-shaped pits; the small number of starch grains, about 6 to 10 microns in diameter, from the parenchyma; the parenchymatous idioblasts filled with microcrystals of calcium oxalate; the only occasional stone cells.

Cinchona **contains** about twenty alkaloids in varying proportions, of which quinine, cinchonidine, cinchonine and quinidine are the most important and abundant. The percentage of total alkaloids usually ranges from about 5 to 10. In addition to the alkaloids, cinchona contains a glycoside, quinovin, cinchona red, cinchotannic, cinnovic, quinic and oxalic acids, starch, colouring matters, wax and fat.

Varieties.—Red cinchona is the bark of *Cinchona succirubra* Pav.; the outer surface is more or less strongly wrinkled longitudinally, older pieces also bearing reddish warts, and the inner surface has a characteristic red-brown colour; the bark is somewhat spongy in texture. It yields about 6 to 9 per cent. of total alkaloid, 1·5 to 3·5 per cent. being quinine. Yellow cinchona is the bark of *Cinchona Calisaya* Wedd.; the outer surface has a periderm which tends to exfoliate, is marked with longitudinal furrows and shows, at distances 6 to 12 millimetres apart, transverse cracks extending entirely across the quills; the inner surface is hard and yellowish-brown in colour. It yields about 6 to 7 per cent. of alkaloid, 3 to 4 per cent. being quinine. Ledger bark is obtained from *Cinchona Ledgeriana* Moens, which is stated to be a hybrid between *C. Miranthera* Ruiz et Pav. and *C. Calisaya*. This bark closely resembles that of *C. Calisaya*, but usually contains a higher proportion of quinine, up to 10 or even 14 per cent. Pale cinchona is the bark of *Cinchona officinalis* Linn. and is distinguished by the small size of the quills, which do not usually exceed about 12 millimetres in diameter, and by the presence on the outer surface of numerous small transverse cracks, the edges of which are recurved. It yields about 6 per cent. of total alkaloid, about one half of which is quinine. Hybrid bark is usually a hybrid between *C. Ledgeriana* and *C. succirubra*; it shows characters intermediate between those of the two cinchonas of which it is a hybrid. It yields a high percentage of quinine.

Substitutes.—Colombian bark, from *Cinchona lancifolia* Mutis, occurs usually in flat or curved pieces about 15 to 50 centimetres long, 4 to 8 centimetres wide, and 2 to 10 millimetres thick. It is reddish-brown in colour and spongy in texture; it bears on the outer surface characteristic patches of silvery cork. Cuprea bark is the bark of *Remijna pedunculata* Flueck (Fam. Rubiaceæ). It is coppery-red, in rather small pieces, 3 to 6 millimetres thick, very hard, with a granular and splintery fracture. It contains about 2 or 3 per cent. of quinine. The bark of *R. Purdieana* Wedd. contains a number of alkaloids amongst which are cinchonine and cinchonidine, but quinine is absent. Naranjada bark from Bolivia is obtained from *Cinchona ovata* Ruiz et Pav. and other species. This bark occurs in flats or large quills of considerable thickness, up to 1 centimetre; the external surface is golden-yellow; it contains about 5 per cent. of total alkaloid, but only a trace of quinine.

Standard, B.P.—Cinchona contains not less than 6 per cent. of the alkaloids of cinchona, of which not less than one half consists of quinine and cinchonidine. It contains not more than 2 per cent. of foreign organic matter. Ash, not more than 4 per cent.

Cinchona, in powder (Pulvis Cinchonæ : Pulv. Cinchon.), contains the constituents and possesses the diagnostic microscopical characters of Cinchona, and complies with the limits for alkaloids and ash of the unground drug.

Action and Uses.—Cinchona is a bitter tonic and stomachic. It has the action of quinine, but is also astringent, more irritating to the stomach and intestines and more slowly absorbed. It occasionally causes vomiting and, if taken in large doses over a prolonged period, may produce symptoms of cinchonism. The liquid extract is used as a tonic for convalescents, with hydrobromic acid and tincture of nuxvomica, and is employed in dipsomania. The compound tincture in large doses is employed as a prophylactic for the common cold, and with syrup of codeine phosphate it is used for the relief of persistent coughs. Cinchona is a useful astringent for the throat, and the decoction or acid infusion is used in gargles. The powdered bark is occasionally used as an ingredient of astringent tooth powders. Liquid preparations of cinchona are best administered in acid media,

which keep the alkaloids in solution. Decoction of cinchona and the tinctures are, however, frequently prescribed with ammonium carbonate, which precipitates the alkaloids, so that they sometimes require to be suspended with syrup or mucilage of acacia. Preparations of cinchona are **incompatible** with salicylates and iodides.

Dose.—0·3 to 1 gramme (5 to 15 grains).

Preparations

Decoctum Cinchonæ Concentratum, B.P.C.—(Dec. Cinchon. Conc.)—Concentrated Decoction of Cinchona. 1 in 2. When decoction of cinchona or Decoctum Cinchonæ is prescribed, this concentrated decoction diluted with seven times its volume of distilled water may be dispensed. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Elixir Cinchonæ, B.P.C.—(Elix. Cinchon.)—Elixir of Cinchona. Tincture of cinchona, about 1 in 6½, with syrup, glycerin and aromatic elixir. Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

Extractum Cinchonæ, B.P.—(Ext. Cinchon.)—Extract of Cinchona. A soft extract prepared with alcohol (90 per cent.) and adjusted with glycerin to contain 10 per cent. of the alkaloids of cinchona (limits, 9·5 to 10·5); 0·5 gramme contains about 0·05 gramme, and 8 grains contains about ½ grain, of alkaloids. It should be stored in small, wide-mouthed, well-closed containers in a cool place. Dose.—0·12 to 0·5 gramme (2 to 8 grains).

Extractum Cinchonæ Liquidum, B.P.—(Ext. Cinchon. Liq.)—Liquid Extract of Cinchona. It contains 5 per cent. w/v of the alkaloids of cinchona in hydrochloric acid solution with glycerin and alcohol (limits, 4·75 to 5·25); 1 millilitre contains about 0·05 gramme and 15 minims contains about ¾ grain. Dose.—0·3 to 1 millilitre (5 to 15 minims).

Infusum Cinchonæ Acidum Concentratum, B.P.C.—(Inf. Cinchon. Acid. Conc.)—Concentrated Acid Infusion of Cinchona. 1 in 2½. This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh acid infusion of cinchona and differs also in containing a small proportion of alcohol. Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

Infusum Cinchonæ Acidum Recens, B.P.C.—(Inf. Cinchon. Acid. Rec.)—Fresh Acid Infusion of Cinchona. Cinchona, 1 in 20, and aromatic sulphuric acid, 1 in 80. When acid infusion of cinchona or Infusum Cinchonæ Acidum is prescribed, fresh infusion not being specified, either Infusum Cinchonæ Acidum Recens, or Infusum Cinchonæ Acidum Concentratum suitably diluted, may be dispensed. Dose.—15 to 30 millilitres (½ to 1 fluid ounce).

This infusion was included in the British Pharmacopœia, 1914, under the name of Infusum Cinchonæ Acidum.

Tinctura Cinchonæ, B.P.—(Tinct. Cinchon.)—Tincture of Cinchona. Extract of cinchona, 10 per cent. w/v, in alcohol (70 per cent.). It contains 1 per cent. w/v of the alkaloids of cinchona (limits, 0·95 to 1·05); 4 millilitres contains 0·04 gramme, and 1 fluid drachm contains about ⅕ grain, of alkaloids. Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

Tinctura Cinchonæ Composita, B.P.—(Tinct. Cinchon. Co.)—Compound Tincture of Cinchona. Extract of cinchona, 5 per cent. w/v, dissolved in the liquid obtained by percolating dried bitter-orange peel, serpentry and cochineal with alcohol (70 per cent.). It contains 0·5 per cent. w/v of the alkaloids of cinchona (limits, 0·475 to 0·525); 4 millilitres contains 0·02 gramme, and 1 fluid drachm contains about ⅕ grain, of alkaloids. Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

CINCHONIDINÆ SULPHAS

(Cinchonidin. Sulph.)

Cinchonidine Sulphate

Cinchonidine sulphate is the sulphate of a base present in cinchona bark. It occurs in the form of colourless, shining, silky crystals, neutral to litmus, without odour, but with a strong, bitter taste. When anhydrous it melts at about 207°.

Soluble in water (1 in 100), more readily on the addition of dilute acid, and in alcohol (1 in 60); almost insoluble in ether and chloroform.

Standard.—Cinchonidine sulphate loses, on drying at 100°, not more than 16 per cent. of its weight. Ash, not more than 0.1 per cent. A solution obtained by dissolving 0.25 gramme in 5 millilitres of sulphuric acid is not coloured more than pale yellow (limit of readily carbonisable substances). A solution (1 in 1000) in dilute sulphuric acid is not more than faintly fluorescent (limit of quinine and quinidine). When 0.5 gramme is shaken with 20 millilitres of water at 15° for some time, 0.5 gramme of sodium potassium tartrate added, and the mixture left with frequent shaking for one hour and then filtered, the filtrate is rendered not more than faintly opalescent on the addition of a drop of dilute solution of ammonia (limit of cinchonine and quinidine).

Action and Uses.—Cinchonidine has much the same action as quinine, but it increases reflexes, and in large doses gives rise to well-marked epileptiform convulsions. It has been observed that even small doses administered to epileptics may increase the frequency of attacks. Cinchonidine, in common with the other crystallisable alkaloids of cinchona bark, has the action of a general protoplasmic poison, being especially toxic to protozoa such as the malaria parasite. Cinchonidine salts are somewhat less efficacious in the treatment of malaria than are salts of the other crystallisable cinchona alkaloids. Cinchonidine sulphate is useful in the treatment of rheumatism and neuralgia in frequently repeated doses of 0.3 gramme (5 grains). It is usually **administered** with dilute sulphuric acid, as in the case of quinine sulphate, to facilitate solution. Pills may be prepared with liquid glucose or glycerin of tragacanth.

Dose.—0.06 to 0.6 gramme (1 to 10 grains).

CINCHONIDINA.—Cinchonidine, $C_{19}H_{22}ON_2$, occurs as short, colourless prisms or thin plates, soluble in 16 parts of alcohol (95 per cent.), and is laevorotatory.

CINCHONIDINÆ SALICYLAS.—Cinchonidine salicylate, $C_{19}H_{22}ON_2 \cdot C_6H_4(OH)COOH$, occurs as a crystalline powder, sparingly soluble in water, but soluble in alcohol. It is specially indicated in acute muscular rheumatism and sciatica, and is given in similar doses to the sulphate. It is useful as a prophylactic against influenza in doses of 0.3 gramme (5 grains) twice daily, and in the treatment of influenza, when it may be given in doses of 0.6 to 1 gramme (10 to 15 grains).

CINCHONIDINÆ DIHYDROCHLORIDUM.—Cinchonidine dihydrochloride, cinchonidine acid hydrochloride, $C_{19}H_{22}ON_2 \cdot 2HCl$, occurs as a white powder. It is readily soluble in water and has been used in the preparation of solutions for intramuscular injection in doses up to 0.5 gramme (8 grains). Solutions for injection may be sterilised by heating in an autoclave, by tyndallisation, or by filtration.

CINCHONINÆ HYDROCHLORIDUM

(Cinchonin. Hydrochlor.)

Cinchonine Hydrochloride

Cinchonine hydrochloride is the hydrochloride of a base present in cinchona bark. It occurs in white, microcrystalline flakes or needles, without odour, but with a bitter taste. It has occasionally been found as an adulterant in quinine sulphate. Its solution is not rendered fluorescent by the addition of sulphuric acid and a dilute neutral solution is not precipitated by sodium potassium tartrate solution.

Soluble in water (1 in 20), alcohol (1 in 2), and ether (1 in 300).

Standard.—Cinchonine hydrochloride loses, on drying at 100° , not more than 10 per cent of its weight. Ash, not more than 0.1 per cent. 1 gramme dissolves completely in 25 millilitres of chloroform. 0.05 gramme dissolved in 1 millilitre of sulphuric acid produces not more than a pale yellow colour (limit of readily carbonisable substances). 10 millilitres of a 1 per cent. solution gives a white precipitate on the addition of 1 millilitre of dilute solution of ammonia, which does not dissolve completely on shaking with 20 millilitres of ether (limit of quinine, quinidine and cinchonidine).

Action and Uses.—Cinchonine is a bitter tonic and antiperiodic; like cinchonidine it differs in its action from quinine, increasing reflexes and, in very large doses, even causing convulsions. The two dextro-rotatory alkaloids, cinchonine and quinidine, have been recommended as substitutes for quinine in the treatment of patients who exhibit idiosyncrasy to the latter alkaloid. Cinchonine salts have the same toxicity when given intravenously as the corresponding quinine salts. When large doses are given subcutaneously or intramuscularly, cinchonine salts cause cinchonism owing to their rapid absorption, which is speedier and more complete than that of quinine salts. When its bitter action is not required, cinchonine hydrochloride may be **administered** in pills; they may be prepared with liquid glucose or glycerin of tragacanth.

Dose.—0.06 to 0.6 gramme (1 to 10 grains).

CINCHONINA.—Cinchonine, $\text{C}_{19}\text{H}_{22}\text{ON}_2$, occurs as a white powder, or as white, lustrous prisms or needles, odourless and at first almost tasteless, but soon developing bitter taste. It is almost insoluble in water (about 1 in 4000), but soluble in ether (about 1 in 500), and alcohol (about 1 in 150.).

CINCHONINÆ DIHYDROCHLORIDUM.—Cinchonine dihydrochloride, cinchonine acid hydrochloride, $\text{C}_{19}\text{H}_{22}\text{ON}_2, 2\text{HCl}$, occurs as a white, odourless powder, having a very bitter taste. It is soluble in water (about 1 in 6), alcohol (1 in 6), and chloroform (1 in 115), and is almost insoluble in ether. Intramuscular injections of cinchonine dihydrochloride are given in relapsing cases of malaria and in the treatment of the malignant tertian variety, in doses of 0.3 to 1 gramme (5 to 15 grains). This treatment is useful in those cases in which quinine causes sickness. Owing to its greater solubility, the dihydrochloride is more suitable

for this purpose than the hydrochloride. Solutions for injection may be sterilised by heating in an autoclave, by tyndallisation, or by filtration.

CINCHONINÆ SULPHAS.—Cinchonine sulphate, $(C_{19}H_{22}ON_2)_2 \cdot H_2SO_4 \cdot 2H_2O$, occurs in small, hard, white, vitreous, prismatic crystals, odourless, and with a very bitter taste. It is soluble in water (about 1 in 70), and alcohol (1 in 10), and is almost insoluble in ether.

CINCHOPHENUM

(Cinchophen.)

Cinchophen

Synonym—Quinophan.

Cinchophen is 2-phenylquinoline-4-carboxylic acid, $C_6H_5 \cdot C_9H_5N \cdot COOH$, and may be prepared by the interaction of pyruvic acid and benzylidene-aniline in the presence of alcohol. It occurs as an odourless, white or cream-coloured powder, or in acicular crystals, and has a slightly bitter taste. The ammoniacal solution when evaporated to small bulk and diluted with water gives a white precipitate with silver nitrate solution, a yellowish precipitate with lead acetate solution and a green precipitate with copper sulphate solution.

Insoluble in water; soluble in alcohol (95 per cent.) (about 1 in 120), ether (about 1 in 100), chloroform (about 1 in 400), and in solutions of alkali hydroxides, carbonates and bicarbonates.

Standard, B.P.—Cinchophen contains not less than 99 per cent. of $C_{16}H_{11}O_2N$, calculated on the dry substance. Loss on drying in a vacuum desiccator over sulphuric acid, not more than 1 per cent. Melting-point, 214° to 217° . Ash, not more than 0.2 per cent. It complies also with a test for absence of soluble acids and with a limit test for readily carbonisable substances.

Action and Uses.—Cinchophen is employed to increase the rate of excretion of uric acid; it appears to assist excretion and not to increase formation since, after its administration, the percentage of uric acid in the blood is definitely diminished. Deposits of urates thus tend to pass into solution. In other respects it exerts an action very similar to that of quinine. Cinchophen is indicated chiefly in acute gout; in non-uratic joint affections its value is doubtful. Care must be taken in the use of this substance since it sometimes has a toxic action on the liver, causing acute yellow atrophy. Toxic effects, such as loss of appetite, nausea, vomiting and jaundice, may easily occur and any one of these should be regarded as an indication for discontinuing the drug. The patient should be under constant observation during treatment. It is best **administered** in tablets, the dose being taken with a large volume of water and 30 to 75 grains of sodium bicarbonate. It is usually given in doses of 0.5 gramme (8 grains), two or three times a day, for three consecutive days; an interval of four days should elapse before treatment is resumed.

Since some patients show an idiosyncrasy, a small preliminary dose should be given before commencing a course of treatment. In order to minimise the possibility of liver damage, it is recommended that dextrose and calcium lactate should be given concurrently with cinchophen.

Dose.—0·3 to 1 gramme (5 to 15 grains).

NEOCINCOPHENUM.—Neocinchophen, neoquinophan, $\text{CH}_3\cdot\text{C}_6\text{H}_4\text{N}\cdot\text{C}_6\text{H}_5\text{COOC}_2\text{H}_5$, is the ethyl ester of 6-methyl-2-phenylquinoline-4-carboxylic acid. It occurs as a slightly yellow, colourless and tasteless powder, which melts at about 76° . It is readily soluble in strong acids and hot alcohol, but insoluble in water and dilute alkalis. Neocinchophen resembles cinchophen in its action and is administered in tablets, with the precautions outlined under cinchophen. **Dose.**—0·3 to 1 gramme (5 to 15 grains).

CINNAMOMUM

(Cinnam.)

Cinnamon

Synonyms—Cinnamomi Cortex; Cinnamon Bark.

Cinnamon consists of the dried inner bark of the shoots of coppiced trees of *Cinnamomum zeylanicum* Nees (Fam. Lauraceæ), a small tree indigenous to and cultivated in Ceylon. It is known in commerce as Ceylon cinnamon. The trees are cut down to form stools from which adventitious shoots arise; these are cut off when about one or two metres in length, the bark is stripped and the epidermis and cortex removed by scraping; the strips are then packed inside one another and dried.

Cinnamon occurs in single or double, closely-packed, compound quills up to about 2 metres in length and about 1 centimetre in diameter. The external surface is dull, yellowish-brown and marked with pale, wavy, longitudinal lines and often with small scars or holes; only rarely do patches of cork occur. The inner surface is darker and marked with faint longitudinal striations. Each quill is about 0·5 millimetre in thickness and is very brittle, breaking with a splintery fracture. The bark has a fragrant odour and a warm, sweet, aromatic taste.

The diagnostic **microscopical** characters are the sclerenchymatous cells of the phelloderm, isodiametric or slightly elongated tangentially, the inner and radial walls often being thicker than the outer, some containing starch grains; the medullary rays, mostly 2 cells wide; the presence in some cells of the medullary rays and of the phloem parenchyma of acicular microcrystals of calcium oxalate; the strongly-thickened phloem fibres, usually under 30 microns in diameter, either isolated or in short tangential rows; the axially elongated secretory cells of the secondary phloem, containing volatile oil or mucilage; the starch grains, either simple or compound, individual grains mostly under 10 microns in diameter; the absence of wood vessels and of all but traces of cork.

Cinnamon contains about 1 to 2 per cent. of volatile oil, with tannin and mucilage. It yields to alcohol (90 per cent.) from about 14 to 16 per cent. of extractive.

Substitutes and Adulterants.—Jungle cinnamon is obtained from wild plants; the bark is darker, coarser, less carefully trimmed and less aromatic than the cultivated bark. Saigon cinnamon is referred to *Cinnamomum Loureiru* Nees; the quills are thicker than those of Ceylon cinnamon and of a greyish or greyish-brown colour with lighter patches, warty and ridged externally, and have a sweeter taste. Java cinnamon is obtained from *Cinnamomum Burmanni* Blume. It may be distinguished by its low yield of extractive to alcohol (90 per cent.) and, microscopically, by the presence in the medullary rays of small tabular crystals of calcium oxalate. The odour is less delicate than that of Ceylon cinnamon. Seychelles cinnamon is said to be obtained from plants of *Cinnamomum zeylanicum* Nees introduced into the Seychelles, where they have become wild. It yields about 14 per cent. of extractive to alcohol (90 per cent.) and the stone cells are usually large. Cinnamon chips consist of small pieces of untrimmed bark; it can be distinguished by its lower yield to alcohol (90 per cent.) and, microscopically, by the abundance of cork. A similar material to "chips", but of a slightly better quality, is known as "featherings."

Standard, B.P.—Cinnamon yields not more than 7 per cent. of ash. Acid-insoluble ash, not more than 2 per cent.

Cinnamon, in powder (Pulvis Cinnamomi: Pulv. Cinnam.), contains the constituents and possesses the diagnostic microscopical characters of *Cinnamomum*, and complies with the standard for the unground drug.

Action and Uses.—Cinnamon is carminative and antiseptic by virtue of its volatile oil, and slightly astringent owing to the tannin it contains. For use in diarrhoea, as an intestinal astringent and stimulant, the powder (as in Pulvis Cinnamomi Compositus or Pulvis Cretæ Aromaticus) or Tinctura Cinnamomi is preferred. Aqua Cinnamomi is a useful aromatic vehicle.

Dose.—0.3 to 1.2 grammes (5 to 20 grains).

Preparations

Aqua Cinnamomi Concentrata, B.P.—(Aq. Cinnam. Conc.)—Concentrated Cinnamon Water. Oil of cinnamon, 1 in 50. One part added to 39 parts of distilled water yields a preparation which is approximately equivalent in strength to distilled cinnamon water, but contains 1.5 per cent. v/v of alcohol (90 per cent.) Dose.—0.3 to 1 millilitre (5 to 15 minims).

This concentrated water was included in the British Pharmacopœia, 1923.

Aqua Cinnamomi Destillata, B.P.—(Aq. Cinnam. Dest.)—Distilled Cinnamon Water. Cinnamon, 1 in 10. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Pulvis Cinnamomi Compositus, B.P.C.—(Pulv. Cinnam. Co.)—Compound Cinnamon Powder. *Syn.*—Pulvis Aromaticus. Equal parts of cinnamon, cardamom and ginger. Dose.—0.6 to 4 grammes (10 to 60 grains).

This powder was included in the British Pharmacopœia, 1914.

Tinctura Cinnamomi, B.P.C.—(Tinct. Cinnam.)—Tincture of Cinnamon. 1 in 5. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopœia, 1914.

Tinctura Cinnamomi Composita, B.P.C.—(Tinct. Cinnam. Co.)—Compound Tincture of Cinnamon. Cinnamon, 1 in 40, with cardamom, long pepper and ginger. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

COCA

(Coca)

Coca*Synonyms*—Cocæ Folia; Coca Leaves.

Coca consists of the dried leaves of *Erythroxylum coca* Lam. (Bolivian or Huanuco leaf) or of *E. truxillense* Rusby (Peruvian or Truxillo leaf) (Fam. Erythroxylaceæ), shrubs indigenous to Bolivia and Peru and cultivated in Java. It should be **stored** in a dry place to prevent hydrolysis of the alkaloid following upon attack by mildew.

The leaves of Bolivian coca are shortly petiolate, elliptical, from 3.5 to 7 centimetres long and from 2.5 to 3.5 centimetres wide, and glabrous; the apex is acute and mucronate, the projecting tip being frequently broken off; the margin is entire, the veinlets prominent on the upper surface, the midrib depressed and surmounted by a raised ridge; on the under surface of the leaf a curved line runs from the base to the apex on either side of the midrib; the leaves are thin but not fragile and are usually unbroken. The leaves of Peruvian coca have the same general characters as the above, but may be distinguished by their smaller size, pale green colour, papery texture, less distinct curved lines and less marked ridges above the midrib and by their broken condition. They were formerly mixed with flowers of a species of *Inga*, an intentional addition made with the object of improving the drug. The odour of both varieties is faint, and the taste is bitter, followed by a sensation of numbness of the tongue.

The diagnostic **microscopical** characters are the papillose cells of the under epidermis; the stomata on the under surface only, accompanied by two cells with their long axes parallel to the ostiole; the prismatic crystals of calcium oxalate in the cortical tissue and in certain cells of the palisade tissue; the absence of hairs.

Coca **contains** the alkaloids, cocaine (methylbenzoyllecgonine), cinnamyl-cocaine (methylecinnamyllecgonine), and α - and β -truxillines (isatropyl-cocaine and methyl- β -truxillylecgonine). The amount of total alkaloid yielded by the commercial leaves varies from about 0.5 to 1.5 per cent. Coca is now frequently valued by its ecgonine content, since much of the cocaine of commerce is synthesised from ecgonine. As a rule, Truxillo and Java leaf contains more alkaloid than Bolivian, but only about one-half of it is cocaine, whereas from 70 to 80 per cent. of the total alkaloid in Bolivian leaf consists of cocaine. Coca also contains cocatannic acid. Coca leaf from Java, said to be derived from *E. truxillense* Rusby, yields from 1 to 2 per cent. of total alkaloid, part of which is benzoylpseudotropine or tropacocaine, and four yellow, crystalline glycosides.

Action and Uses.—Coca has virtually the same action as that of cocaine, although preparations of the drug appear rather more stimulating and possess a mild astringency. In Peru and Bolivia, coca leaf is chewed for its effect in relieving hunger and fatigue. The leaf

has been used as a cerebral and muscle stimulant, especially during convalescence; it relieves gastric pain, nausea and vomiting. Coca is usually administered in the form of elixir and liquid extract. In cases of **poisoning** by preparations of coca, the antidotes described under Cocaina should be employed.

Dose.— 1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

ERYTHROPHLEUM.—*Erythrophloeum*, or sassy bark, is the bark of the trunk and branches of *Erythrophloeum guineense* G. Don (Fam. Leguminosæ), a large tree indigenous to the Guinea Coast of Africa and to the neighbourhood of the Congo, and widely, but sparsely, distributed throughout a great part of Africa. The bark occurs in quills about 1·5 centimetres in diameter or in hard, heavy, curved or flat pieces, often from about 7·5 to 10 centimetres long, 5 to 7·5 centimetres wide, and 5 to 9 millimetres thick. The outer surface is warty and irregular, and of a dark reddish colour, often exhibiting, in the older pieces, large conchoidal depressions. The inner surface is longitudinally striated, and is of a dark reddish-brown or nearly black colour; the fracture is short and granular; the smoothed, transversely cut surface exhibits a narrow, brown cork and a narrow and darker cortex separated from the phloem by a pale line of sclerenchymatous cells; the phloem contains numerous large, paler groups of sclerenchymatous cells embedded in a reddish-brown parenchymatous tissue. The drug has no odour, and only a slightly bitter, astringent taste. *Erythrophloeum* contains a poisonous alkaloid, erythrophloëine, which resembles digitalis in its pharmacological properties and has been used as an anæsthetic in dentistry. A 50 per cent. solution of the sulphate in eugenol has been used as an obtundent.

Preparations

Elixir Cocæ, B.P.C.—(Elix. Cocæ).—Elixir of Coca. Liquid extract of coca, about 1 in 6, in simple elixir. Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

Extractum Cocæ Liquidum, B.P.C.—(Ext. Cocæ Liq).—Liquid Extract of Coca. *Syn.*—Miscible Liquid Extract of Coca. This liquid extract contains from 0·45 to 0·55 per cent. w/v of ether-soluble alkaloids calculated as cocaine; 4 millilitres contains about 0·02 gramme, and 1 fluid drachm contains about $\frac{1}{4}$ grain, of alkaloids. Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

COCAINA

(Cocain.)

Cocaine

Cocaine is methylbenzoylægonine and occurs, together with varying proportions of other alkaloids of closely related structure, in a number of species of *Erythroxylum*. The total alkaloids are obtained from the leaves by admixture with lime and subsequent percolation with naphtha or other similar solvent. From the crude mixture of alkaloids thus obtained, cocaine is prepared either directly, by suitable methods of purification, or by acid hydrolysis of the crude product, whereby the various alkaloids are broken down to ægonine. This is isolated and purified, and on methylation and benzylation gives cocaine. The greater part of the cocaine of commerce is now prepared from Java leaves by the latter procedure.

Cocaine occurs in colourless, odourless crystals, having a bitter taste followed by a sensation of tingling and numbness of the tongue. It is readily soluble in acids, giving salts which are laevorotatory in solution. When heated at 100° for five minutes with sulphuric acid mixed with twice its volume of water, methyl benzoate is formed, together with benzoic acid which separates on allowing the liquid to stand for a few hours. When a trace of cocaine is dissolved in the minimum quantity of N/10 hydrochloric acid, a few millilitres of solution of alum added, followed by 3 or 4 millilitres of N/10 potassium permanganate solution, violet, rectangular plates separate after stirring the mixture briskly for a few seconds.

Very slightly **soluble** in water (about 1 in 1300); more soluble in alcohol (90 per cent.) (1 in 10), ether (1 in 4), chloroform (2 in 1), oleic acid (1 in 4), olive oil (1 in 24), castor oil (1 in 10), liquid paraffin or soft paraffin (1 in about 120), oil of turpentine (1 in 14), warm anhydrous lanolin (1 in 2) and benzene (1 in 3); also soluble in toluene, amyl alcohol and light petroleum, but insoluble in glycerin.

Standard, B.P.—Cocaine has a melting-point of 97° to 98° . Ash, not more than 0.1 per cent. It complies also with a test for absence of isatropyl-cocaine, and with limit tests for readily carbonisable substances, and for reducing substances and cinnamyl-cocaine.

Action and Uses.—Cocaine is a powerful local anæsthetic. Mucous surfaces are rendered insensible by simple application of the drug. Hypodermic injection results in a cutaneous anæsthesia; 12 millilitres (20 minims) of a 2 per cent. w/v solution of a cocaine salt produces local anæsthesia in from five to twenty minutes, lasting for about twenty minutes. It is used as a local anæsthetic prior to tooth extraction, injection being necessary to reach the dental nerves. In many cases it is injected with adrenaline, the latter localising the action of the cocaine by its vasoconstrictor effect. It is an effective spinal anæsthetic, but is too dangerous to justify its use for that purpose. Cocaine has an important place in ophthalmic surgery owing to its certainty of action, and also to its action in blanching the conjunctiva and dilating the pupil. These points are responsible for its superiority over the numerous substitutes that have to some extent replaced it for use in other regions of the body. Soon after absorption, cocaine causes a sense of exhilaration and well-being, due to stimulation of the cerebral cortex. There is also an increased power to work and overcome fatigue. Large doses cause restlessness, tremors and hallucinations. Some people have a distinct cocaine idiosyncrasy and may become dangerously ill after quite small doses; the symptoms are headache, faintness and collapse, and may occur with alarming rapidity.

The prolonged use of cocaine may result in the formation of a habit; cocaine addicts inject it hypodermically or use it in the form of a snuff. The addict suffers from sleeplessness, loss of memory and an intolerable craving for the drug; loss of weight is usually marked, and the person undergoes mental deterioration, relapsing ultimately into a state of permanent moral degeneracy with lack of social responsibility.

When used as a snuff, the action of cocaine is very rapid, a state of exhilaration or irresponsibility, according to the individual, being rapidly reached.

Cocaine is used chiefly in the form of its salts, such as the hydrochloride, nitrate and salicylate, but the alkaloid may be used in combination with fatty or oily bases, as in suppositories, ointments and oily spray-solutions. Cocaine ointment relieves pruritus and the irritation of urticaria or eczema, and the pain of hæmorrhoids and facial neuralgia. Unguentum Cocainæ is not suitable for ophthalmic use, for which purpose Oculentum Cocainæ should be employed. Spray-solutions are used in hay fever, asthma, pharyngitis and laryngitis; they may be oily solutions of the pure alkaloid or aqueous solutions of its salts. Liquid paraffin will retain less than 1 per cent. w/v of cocaine in permanent solution. Stronger solutions (2 to 5 per cent. w/v) may be prepared with almond oil or a mixture of almond oil and liquid paraffin. For external application to chilblains, a 2 per cent. w/v solution of cocaine in collodion may be used. For tooth-ache, a 5 to 10 per cent. w/v solution in oil of clove has been used. A very moderate heat should be used in the preparation of oily solutions of cocaine. Solutions in oils and fats are less active than aqueous solutions of cocaine salts. In cases of **poisoning** by cocaine, strong coffee should be given by the mouth or rectum, and the usual means adopted to combat shock or cardiac failure.

Dose.—0·008 to 0·016 gramme ($\frac{1}{8}$ to $\frac{1}{4}$ grain).

Preparations

Buginaria Cocainæ, B.P.C.—(Bugin. Cocain.)—Cocaine Urethral Bougies. Each bougie contains $\frac{1}{2}$ grain of cocaine.

Guttæ Cocainæ, B.P.C.—(Gutt. Cocain.)—Cocaine Eye Drops. *Syn.*—Factory Eye Drops. Cocaine, 1 in 200, with mercuric chloride, in castor oil.

Nebula Cocainæ Composita, B.P.C.—(Neb. Cocain. Co.)—Compound Cocaine Spray. Cocaine, 0·5 per cent. w/v, in compound menthol and thymol spray.

Unguentum Cocainæ, B.P.C.—(Ung. Cocain.)—Cocaine Ointment. Cocaine, 4 per cent., in oleic acid and lard.

This ointment was included in the British Pharmacopœia, 1914.

COCAINÆ HYDROCHLORIDUM

(Cocain. Hydrochlor.)

Cocaine Hydrochloride

Synonym—Cocaini hydrochloridum I.A.

Cocaine hydrochloride is the hydrochloride of the alkaloid cocaine. It occurs in colourless, odourless, transparent crystals, having a bitter taste followed by a sensation of tingling and numbness of the tongue. The aqueous solution is lævorotatory and gives the reactions of chlorides. On the addition of one or two drops of chromium trioxide

solution to a 1 per cent. solution of cocaine hydrochloride, a yellow precipitate is formed which re-dissolves on shaking; a permanent yellow precipitate is formed on adding a few more drops of the chromium trioxide solution. Cocaine hydrochloride responds to the tests with sulphuric acid and with potassium permanganate described under Cocaina.

Soluble in water (2 in 1), alcohol (90 per cent.) (1 in 3), glycerin (1 in 3) and chloroform (1 in 20); insoluble in oils and almost insoluble in ether.

Standard, B.P.—Cocaine hydrochloride, when placed in the heating bath at 193° , has a melting-point not lower than 197° . Specific rotation in 2 per cent. w/v aqueous solution, -70° to -72° . Ash, not more than 0.1 per cent. It complies with a test for absence of isatropyl-cocaine and with limit tests for acidity, readily carbonisable substances and reducing substances, and for cinnamyl-cocaine.

Action and Uses.—Cocaine hydrochloride is generally suitable for use in aqueous solutions, except for preparations containing silver or lead, when cocaine nitrate should be used. Freshly boiled and cooled distilled water must be used in the preparation of cocaine solutions, on account of their tendency to develop fungoid growths. Solutions for ophthalmic use contain from 2 to 4 per cent. Pastilles contain from 0.0015 gramme ($\frac{1}{16}$ grain) to 0.01 gramme ($\frac{1}{6}$ grain) in each, and lozenges are prepared of the same strengths for use against throat irritation and hoarseness. Solutions of cocaine hydrochloride (5 to 10 per cent. w/v) are applied locally to mucous surfaces previous to operation. For the production of deep-seated anaesthesia, local infiltration is resorted to, solution of adrenaline being commonly added to the solution to constrict the blood vessels and so reduce hæmorrhage. The local anaesthesia so produced is more prolonged than with cocaine hydrochloride only, and there is less danger of rapid absorption. *Injectio Cocainæ Hypodermica* of the British Pharmacopœia, 1914, contained 5 per cent. w/v of the salt and 0.15 per cent. w/v of salicylic acid in distilled water and was administered in doses of 5 to 10 minims. For infiltration anaesthesia, cocaine is largely superseded by synthetic compounds such as procaine hydrochloride. Solutions may be **sterilised** by tyndallisation or by filtration. The containers should comply with the tests for limit of alkalinity of glass. Pessaries and suppositories of cocaine are made with the hydrochloride when rapid action is required; when prolonged action is desired, they should be made with the alkaloid.

Cocaine hydrochloride is **incompatible** with borax. A clear solution is formed if equal weights of borax and boric acid are dissolved before adding the cocaine salt in solution. Cocaine hydrochloride forms an insoluble compound with mercuric chloride and should not be prescribed therewith. It is also incompatible with alkalis and alkali carbonates, phenol, tannic acid, mercuric oxide and soluble silver salts. In cases of **poisoning**, the antidotes described under Cocaina should be used.

Dose.—0.008 to 0.016 gramme ($\frac{1}{8}$ to $\frac{1}{4}$ grain).

COCAINÆ NITRAS.—Cocaine nitrate, $C_{17}H_{21}O_4N, HNO_3$, occurs in large, colourless, tabular crystals which are readily soluble in water and alcohol, and slightly soluble in ether. Cocaine nitrate is employed for the same purposes as the hydrochloride, but can be prescribed with silver nitrate, or may be applied before the silver salt, to lessen the pain caused by the latter. Dose.—0·008 to 0·016 gramme ($\frac{1}{8}$ to $\frac{1}{4}$ grain).

COCAINÆ SALICYLAS.—Cocaine salicylate, $C_{17}H_{21}O_4N, C_7H_6O_3$, occurs in white, deliquescent, crystalline masses, soluble in water and alcohol. For internal use or hypodermic injection, cocaine salicylate possesses no advantage over the hydrochloride. It is sometimes used in eye lotions with sodium salicylate. Dose.—0·008 to 0·016 gramme ($\frac{1}{8}$ to $\frac{1}{4}$ grain).

TROPACOCAINÆ HYDROCHLORIDUM.—Tropacocaine hydrochloride is the hydrochloride of benzoylepseudotropine, which is a by-product in the manufacture of cocaine, or it may be prepared synthetically. It occurs as a white, crystalline powder slightly soluble in alcohol, but readily soluble in water, giving a neutral solution; it melts at 271°. It is used as an anæsthetic in the form of a 1 to 5 per cent. solution.

Preparations

Insufflatio Mentholis et Cocainæ, B.P.C.—(Insuff. Menthol. et Cocain.)—Menthol and Cocaine Insufflation. *Syn.*—Menthol and Cocaine Snuff. Menthol, 2·5 per cent., and cocaine hydrochloride, 0·14 per cent., with ammonium chloride, camphor and lycopodium.

Lamella Cocainæ, B.P.—(Lamell. Cocain.)—Lamella of Cocaine. Each lamella contains 0·0013 gramme ($\frac{1}{10}$ grain) of cocaine hydrochloride.

Nebula Adrenalinæ et Cocainæ, B.P.C.—(Neb. Adrenal. et Cocain.)—Adrenaline and Cocaine Spray. Adrenaline, as solution of adrenaline hydrochloride, 1 in 5000, cocaine hydrochloride, 1 in 100, with chlorbutol and sodium chloride, in distilled water.

Oculentum Atropinæ et Cocainæ, B.P.C.—(Oculent. Atrop. et Cocain.)—Atropine and Cocaine Eye Ointment. Atropine sulphate, about 0·25 per cent., and cocaine hydrochloride, about 0·5 per cent., in simple eye ointment.

Oculentum Cocainæ, B.P.—(Oculent. Cocain.)—Cocaine Ointment for the Eye. Cocaine hydrochloride, 0·25 per cent., in simple eye ointment. It should be stored in small, well-closed containers in a cool place away from light.

An ointment for the eye, prepared with 2 per cent. of cocaine and white soft paraffin, was included in the British Pharmaceutical Codex, 1923.

Pastilli Mentholis et Cocainæ, B.P.C.—(Pastill. Menthol. et Cocain.)—Menthol and Cocaine Pastilles. Each pastille contains $\frac{1}{20}$ grain of menthol and $\frac{1}{40}$ grain of cocaine hydrochloride.

Solvellæ Boracis et Cocainæ Compositæ, B.P.C.—(Solv. Borac. et Cocain. Co.)—Compound Solution-Tablets of Borax and Cocaine. Each tablet contains 5 grains of sodium chloride, 3 grains of borax, 1 grain of boric acid, $\frac{1}{2}$ grain of sodium benzoate and $\frac{1}{10}$ grain of cocaine hydrochloride, with menthol, thymol and oil of sweet birch.

Suppositorium Adrenalinæ et Cocainæ, B.P.C.—(Supp. Adrenal. et Cocain.)—Adrenaline and Cocaine Suppository. Each suppository contains $\frac{1}{20}$ grain of adrenaline and $\frac{1}{4}$ grain of cocaine hydrochloride.

Trochiscus Krameria et Cocainæ, B.P.—(Troch. Kramer. et Cocain.)—Lozenge of Krameria and Cocaine. *Syn.*—Krameria and Cocaine Lozenge. Each lozenge contains approximately 0·06 gramme or 1 grain of dry extract of krameria and approximately 0·003 gramme or $\frac{1}{20}$ grain of cocaine hydrochloride.

Unguentum Adrenalinæ et Cocainæ, B.P.C.—(Ung. Adrenal. et Cocain.)—Cocaine and Adrenaline Ointment. Adrenaline, 0·1 per cent., as borate, and cocaine hydrochloride, 1 per cent., in hydrous wool fat and white soft paraffin.

COCCULUS INDICUS

(Cocc. Ind.)

Cocculus Indicus*Synonym*—Cocculus; Levant Berries.

Cocculus indicus is the fruit of *Anamirta paniculata* Colebr. (Fam. Menispermaceæ), a climbing shrub indigenous to Eastern India and the Malay Archipelago. The fruit is collected when ripe, and dried.

The fruit is brownish-black in colour, finely wrinkled, about 11 to 12 millimetres in length, 9 to 10 millimetres in width, and 6 millimetres thick, being sub-reniform in shape. The pericarp is hard and tough, and about 1 millimetre thick; it bears, on the concave side, the circular scar of the stalk, and also a minute prominence, the remains of the style; joining these two there is a slight ridge about 5 millimetres long. The pericarp encloses a single oily, cup-shaped seed, into the hollow of which an ingrowth of the mesocarp and endocarp projects. The seed shows a crescent-shaped section when the fruit is cut either transversely or longitudinally. The fruit is odourless; the seed has a bitter taste, but the pericarp is tasteless.

Cocculus indicus **contains** the bitter, poisonous substance, picrotoxin, which occurs in the seeds to the extent of 1·0 to 1·5 per cent., associated with a little cocculin (animirtin). The seeds also contain about 50 per cent. of fat. In the pericarp of the fruit two tasteless alkaloids, menispermine and paramenispermine, have been found.

Action and Uses.—*Cocculus indicus* has an action similar to that of picrotoxin, which is generally preferred to the crude drug. *Cocculus indicus* has been used in the form of ointment (1 in 60) for destroying pediculi; a tincture (1 in 10) and a liquid extract (1 in 1) have also been prepared, generally for external use. The drug has been used as a fish-poison. In cases of **poisoning**, the antidotes described under *Picrotoxinum* should be employed.

COCCUS

(Cocc.)

Cochineal*Synonym*—Coccus Cacti.

Cochineal is the dried female insect, *Dactylopius coccus* Costa (Order Hemiptera), containing eggs and larvæ. The insects are indigenous to Central America and Mexico, but the drug is now chiefly obtained from the Canary Islands where the insects are reared upon the branches of various species of *Nopalea* (Fam. Cactaceæ). After fecundation, the insects increase in size and develop an abundance of red colouring matter. They are then brushed off the plant, killed by the fumes of burning sulphur or charcoal, or by heat, and dried in the sun.

The dried insects are purplish-black or purplish-grey in colour, and about 3.5 to 5.5 millimetres long and 3 to 4.5 millimetres broad, oval in outline, flat or slightly concave on the ventral side, and convex on the dorsal. The dorsal surface is transversely wrinkled, showing about eleven segments. The ventral surface of a whole insect carries upon the anterior part, two 7-jointed straight antennæ, three pairs of short legs, each leg terminating in a single claw, and a mouth from which projects the remains of a filiform proboscis. Numerous short, tubular wax-glands are scattered over the dermis, either singly or in groups. Each insect contains numerous larvæ, usually about 150, the proboscides of which appear as two circular coils, one in each side of the head of each larva. The drug is readily reduced to a red or puce-coloured powder. The odour and taste are characteristic.

Cochineal **contains** about 10 per cent. of carminic acid, which occurs as small, red, prismatic crystals, soluble in water, alcohol and alkaline solutions. About 10 per cent. of fat and 2 per cent. of wax are also present, as well as albuminoids and inorganic matter. The fat consists almost entirely of free oleic, linoleic, and myristic acids. The tinctorial values of different specimens may be compared by titrating the solutions with chlorinated soda solution.

Varieties.—"Black grain" cochineal is uniform purplish-black and consists of insects of which the waxy secretion has been melted by the heat applied during preparation for the market. "Silver grain" cochineal is greyish-white and retains the waxy covering in its original condition.

Adulterants.—Cochineal is often artificially weighted with inorganic matter. In the case of the "silver grain" variety, barium or lead carbonate or sulphate is used, while the "black grain" variety may be "faced" with graphite, ivory black, or manganese dioxide, or may contain very dark grains of magnetic sand containing iron.

Standard, B.P.—Cochineal contains not more than 2 per cent. of foreign organic matter. Ash, not more than 7 per cent. No insoluble powder separates when the unground drug is placed in water.

Uses.—Cochineal, in the form of tincture or solution, is used principally as a colouring agent. For many purposes, owing to its greater stability and more constant colouring power in both acid and alkaline solutions, solution of bordeaux B is often preferred to preparations of cochineal (see *Azorubrum*). Tincture of cochineal is also used as an indicator.

Preparations.

Liquor Cocci, B.P.C.—(Liq. Cocc.)—Solution of Cochineal. *Syn.*—Liquid Cochineal. Cochineal, 10 per cent. w/v, with potassium carbonate, potassium citrate, alcohol (90 per cent.) and distilled water.

Liquor Rosæ Dulcis, B.P.C.—(Liq. Ros. Dulc.)—Sweet Solution of Rose. Cochineal, 1 in 25, with oil of rose, potassium carbonate, potassium acid tartrate, potash alum, glycerin, alcohol (90 per cent.) and distilled water.

Tinctura Cocci, B.P.—(Tinct. Cocc.)—Tincture of Cochineal. Cochineal, 1 in 10, prepared by maceration with alcohol (45 per cent.). Dose.—0.3 to 1 millilitre (5 to 15 minims).

CODEINA

(Codein.)

Codeine

Codeine is morphine monomethylether and may be obtained from opium or by the methylation of morphine. It occurs in colourless, odourless, translucent crystals, or as a crystalline powder, with a bitter taste. When 1 millilitre of a 10 per cent. solution of codeine in sulphuric acid is warmed with 1 drop of ferric chloride solution or of ammonium molybdate solution, a bluish-violet colour is produced which changes to red on the addition of one drop of dilute nitric acid. Codeine yields a yellow colouration with nitric acid. It is precipitated from dilute solutions of its salts by sodium or potassium hydroxide solution, but not by ammonia, and the oily precipitate first formed becomes crystalline on standing. It should be **stored** in well-closed containers and protected from light.

Soluble in water (1 in 120), boiling water (1 in 20), alcohol (90 per cent.) (1 in 2), ether (1 in 20), chloroform (1 in 2) and benzene (1 in 13); freely soluble in amyl alcohol, methyl alcohol and carbon disulphide; slightly soluble in light petroleum.

Standard, B.P.—Codeine, after drying at 100°, has a melting-point of 155° to 156°. Loss on drying at 100°, not more than 6 per cent. Ash, not more than 0.1 per cent. It complies also with limit tests for readily carbonisable substances and for morphine.

Action and Uses.—Codeine has only a mild hypnotic action; it does not depress the respiratory centre to the same extent as morphine, and does not arrest secretion, but it nevertheless diminishes local irritation in the respiratory organs. It is, therefore, much used to allay cough, especially the cough of phthisis, and is useful in insomnia where sleeplessness is caused by incessant coughing. Codeine is less constipating than morphine and is excreted by the kidneys. Like morphine, codeine decreases sugar in the urine in diabetes owing to its effect on metabolism, but it is not used in the treatment of diabetes. Codeine allays abdominal pain without giving rise to depression or preventing the action of the bowels. Habit formation from its continuous use is almost unknown. It is used in the withdrawal treatment of morphine addiction. Codeine may be **administered** in pills or tablets, often with antipyretics or with nux vomica and cascara sagrada. For solutions, the more soluble codeine phosphate is better than the free alkaloid. In cases of **poisoning** by codeine, the procedure adopted for Morphina should be followed.

Dose.—0.016 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

APOCODEINÆ HYDROCHLORIDUM.—Apocodeine hydrochloride is the salt of the base or mixture of bases obtained by the action of zinc chloride and hydrochloric acid on codeine. It occurs as a yellowish or greenish-grey, hygroscopic,

The dried insects are purplish-black or purplish-grey in colour, and about 3.5 to 5.5 millimetres long and 3 to 4.5 millimetres broad, oval in outline, flat or slightly concave on the ventral side, and convex on the dorsal. The dorsal surface is transversely wrinkled, showing about eleven segments. The ventral surface of a whole insect carries upon the anterior part, two 7-jointed straight antennæ, three pairs of short legs, each leg terminating in a single claw, and a mouth from which projects the remains of a filiform proboscis. Numerous short, tubular wax-glands are scattered over the dermis, either singly or in groups. Each insect contains numerous larvæ, usually about 150, the proboscides of which appear as two circular coils, one in each side of the head of each larva. The drug is readily reduced to a red or puce-coloured powder. The odour and taste are characteristic.

Cochineal **contains** about 10 per cent. of carminic acid, which occurs as small, red, prismatic crystals, soluble in water, alcohol and alkaline solutions. About 10 per cent. of fat and 2 per cent. of wax are also present, as well as albuminoids and inorganic matter. The fat consists almost entirely of free oleic, linoleic, and myristic acids. The tinctorial values of different specimens may be compared by titrating the solutions with chlorinated soda solution.

Varieties.—"Black grain" cochineal is uniform purplish-black and consists of insects of which the waxy secretion has been melted by the heat applied during preparation for the market. "Silver grain" cochineal is greyish-white and retains the waxy covering in its original condition.

Adulterants.—Cochineal is often artificially weighted with inorganic matter. In the case of the "silver grain" variety, barium or lead carbonate or sulphate is used, while the "black grain" variety may be "faced" with graphite, ivory black, or manganese dioxide, or may contain very dark grains of magnetic sand containing iron.

Standard, B.P.—Cochineal contains not more than 2 per cent. of foreign organic matter. Ash, not more than 7 per cent. No insoluble powder separates when the unground drug is placed in water.

Uses.—Cochineal, in the form of tincture or solution, is used principally as a colouring agent. For many purposes, owing to its greater stability and more constant colouring power in both acid and alkaline solutions, solution of bordeaux B is often preferred to preparations of cochineal (see *Azorubrum*). Tincture of cochineal is also used as an indicator.

Preparations.

Liquor Cocci, B.P.C.—(Liq. Cocc.)—Solution of Cochineal. *Syn.*—Liquid Cochineal. Cochineal, 10 per cent. w/v, with potassium carbonate, potassium citrate, alcohol (90 per cent.) and distilled water.

Liquor Rosæ Dulcis, B.P.C.—(Liq. Ros. Dulc.)—Sweet Solution of Rose. Cochineal, 1 in 25, with oil of rose, potassium carbonate, potassium acid tartrate, potash alum, glycerin, alcohol (90 per cent.) and distilled water.

Tinctura Cocci, B.P.—(Tinct. Cocc.)—Tincture of Cochineal. Cochineal, 1 in 10, prepared by maceration with alcohol (45 per cent.). Dose.—0.3 to 1 millilitre (5 to 15 minims).

CODEINA

(Codein.)

Codeine

Codeine is morphine monomethylether and may be obtained from opium or by the methylation of morphine. It occurs in colourless, odourless, translucent crystals, or as a crystalline powder, with a bitter taste. When 1 millilitre of a 10 per cent. solution of codeine in sulphuric acid is warmed with 1 drop of ferric chloride solution or of ammonium molybdate solution, a bluish-violet colour is produced which changes to red on the addition of one drop of dilute nitric acid. Codeine yields a yellow colouration with nitric acid. It is precipitated from dilute solutions of its salts by sodium or potassium hydroxide solution, but not by ammonia, and the oily precipitate first formed becomes crystalline on standing. It should be **stored** in well-closed containers and protected from light.

Soluble in water (1 in 120), boiling water (1 in 20), alcohol (90 per cent.) (1 in 2), ether (1 in 20), chloroform (1 in 2) and benzene (1 in 13); freely soluble in amyl alcohol, methyl alcohol and carbon disulphide; slightly soluble in light petroleum.

Standard, B.P.—Codeine, after drying at 100°, has a melting-point of 155° to 156°. Loss on drying at 100°, not more than 6 per cent. Ash, not more than 0.1 per cent. It complies also with limit tests for readily carbonisable substances and for morphine.

Action and Uses.—Codeine has only a mild hypnotic action; it does not depress the respiratory centre to the same extent as morphine, and does not arrest secretion, but it nevertheless diminishes local irritation in the respiratory organs. It is, therefore, much used to allay cough, especially the cough of phthisis, and is useful in insomnia where sleeplessness is caused by incessant coughing. Codeine is less constipating than morphine and is excreted by the kidneys. Like morphine, codeine decreases sugar in the urine in diabetes owing to its effect on metabolism, but it is not used in the treatment of diabetes. Codeine allays abdominal pain without giving rise to depression or preventing the action of the bowels. Habit formation from its continuous use is almost unknown. It is used in the withdrawal treatment of morphine addiction. Codeine may be **administered** in pills or tablets, often with antipyretics or with nux vomica and cascara sagrada. For solutions, the more soluble codeine phosphate is better than the free alkaloid. In cases of **poisoning** by codeine, the procedure adopted for Morphina should be followed.

Dose.—0.016 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

APOCODEINÆ HYDROCHLORIDUM.—Apocodeine hydrochloride is the salt of the base or mixture of bases obtained by the action of zinc chloride and hydrochloric acid on codeine. It occurs as a yellowish or greenish-grey, hygroscopic,

amorphous powder, freely soluble in water and less soluble in alcohol. Apocodeine hydrochloride has an action somewhat similar to that of apomorphine; it is a more pronounced expectorant but a milder emetic. It is sometimes used in the treatment of bronchitis, 2 millilitres (30 minims) of a 1 per cent. solution producing free expectoration. The same dose given hypodermically acts as a purgative, causing purgation in fifteen to thirty minutes which may be accompanied by vomiting. Dose.—0·006 to 0·06 gramme ($\frac{1}{16}$ to 1 grain).

Preparations

Gelatinum Codeinæ, B.P.C.—(Gelat. Codein.)—Codeine Jelly. 1 in 500. Dose.—4 grammes (1 drachm.)

Tabellæ Acetanilidi Compositæ cum Codeina, B.P.C.—(Tab. Acetanilid. Co. c. Codein.)—Compound Tablets of Acetanilide with Codeine. Each tablet contains 2 grains of acetanilide, $\frac{1}{2}$ grain of caffeine, 1 grain of sodium bicarbonate and $\frac{1}{4}$ grain of codeine. Dose.—1 or 2 tablets.

CODEINÆ PHOSPHAS

(Codein. Phosph.)

Codeine Phosphate

Codeine phosphate occurs in colourless, odourless, acicular crystals or as a crystalline powder, having a bitter taste and an acid reaction. It gives the reactions described under codeine. The anhydrous base is obtained by adding sodium hydroxide to an aqueous solution, allowing the precipitated oil to stand until crystalline, and then washing the precipitate and drying at 100°. Codeine phosphate should be **stored** in well-closed containers and protected from light.

Soluble in water (1 in 3·5), and alcohol (90 per cent.) (1 in 350); slightly soluble in ether and chloroform.

Standard, B.P.—Codeine phosphate loses, on drying at 100°, not less than 4 per cent. and not more than 7 per cent. of its weight. It complies also with limit tests for morphine, chloride and sulphate.

Action and Uses.—Codeine phosphate, on account of its greater solubility in water, is preferred to codeine for the preparation of syrups, linctuses and injections. Solutions for **injection** may be sterilised by tyndallisation, by filtration, or by heating at 100° for one hour, and should be stored protected from light.

Dose.—0·016 to 0·06 gramme ($\frac{1}{4}$ to 1 grain).

CODEINÆ HYDROCHLORIDUM.—Codeine hydrochloride, $\text{C}_{18}\text{H}_{21}\text{O}_3\text{N}, \text{HCl}, 2\text{H}_2\text{O}$, occurs as a white, crystalline powder with a bitter taste. It is soluble in water (1 in 30). Dose.—0·016 to 0·06 gramme ($\frac{1}{4}$ to 1 grain).

CODEINÆ SULPHAS.—Codeine sulphate, $(\text{C}_{18}\text{H}_{21}\text{O}_3\text{N})_2, \text{H}_2\text{SO}_4, 5\text{H}_2\text{O}$, occurs as white crystals or as a white, crystalline powder, efflorescing in air and having a bitter taste. It is soluble in water (1 in 40), slightly soluble in alcohol, and insoluble in chloroform and ether. Dose.—0·016 to 0·06 gramme ($\frac{1}{4}$ to 1 grain).

Preparations

Linctus Codeinæ, B.P.C.—(Linct. Codein.)—Linctus of Codeine. Each fluid drachm contains codeine phosphate, $\frac{1}{2}$ grain, with citric acid, emulsion of chloroform, glycerin and mucilage of tragacanth. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Syrupus Codeinæ Phosphatis, B.P.C.—(Syr. Codein. Phosph.)—Syrup of Codeine Phosphate. Codeine phosphate, 1 in 200, with distilled water and syrup; each fluid drachm contains about $\frac{1}{2}$ grain of codeine phosphate. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

This syrup was included in the British Pharmacopæia, 1914.

Syrupus codeini I.A. contains 0.2 per cent. of codeine in the form of the base or of a salt.

COLCHICI CORMUS

(Colch. Corm.)

Colchicum Corm

Colchicum corm is the corm of the meadow saffron, *Colchicum autumnale* Linn. (Fam. Liliaceæ), a plant widely distributed over Central and Southern Europe and common in parts of England. It is collected in early summer after the leaves have died down, and is used either fresh or after preparation by removing the coats, slicing transversely and drying at a temperature not higher than 65°.

The fresh corm is about 35 millimetres long and 25 millimetres broad; it is somewhat conical in shape, rounded on one side and flattened on the other, with a small depression near the base containing a bud. The corm is enclosed in a thin, brown, membranous outer coat and a reddish-yellow inner coat. Internally, it is white and solid and, when cut, it yields a whitish, turbid juice having a disagreeable odour and bitter taste. The dried corm occurs in slices about 2 to 5 millimetres thick and sub-reniform to ovate in outline, with yellowish-brown edges. The slices are hard and break readily with a short, mealy fracture; the cut surfaces are white and starchy and show vascular strands as small greyish points. The transverse surface treated with hydrochloric acid or sulphuric acid (20 per cent. v/v) assumes a yellow colour. The drug is odourless and has a bitter, acrid taste.

The diagnostic **microscopical** characters are the brown epidermal cells with indistinctly pitted, slightly wavy walls; the abundant large-celled parenchyma containing numerous starch grains, usually compound, with 2 to 4 or up to 7 components, but sometimes single, individual grains being spherical or ovoid to polyhedral or muller-shaped, 3 to 30 microns in diameter, with a triangular or stellate, central hilum; the occasional vessels, with spiral or annular thickening; the absence of sclerenchyma and calcium oxalate crystals.

Colchicum corm **contains** the alkaloid, colchicine (usually about 0.4 per cent. calculated on the dried corm); it also contains starch, gum, sugar, tannin, colouring matter and fat. The dried corm yields about 4 per cent. of ash.

Standard, B.P.—Colchicum corm contains not more than 2 per cent. of foreign organic matter, and the dried corm contains not less than 0·25 per cent. of colchicine.

Colchicum corm, in powder (*Pulvis Colchici Cormi* : *Pulv. Colch. Corm.*), contains the constituents and possesses the diagnostic microscopical characters of *Colchici Cormus*, and complies with the limit for colchicine of the dried unground drug.

Action and Uses.—Colchicum relieves the pain and inflammation of acute gout, but does not increase the quantity of the urine or the amount of uric acid excreted. It may cause considerable gastrointestinal irritation with vomiting and purging. Its use for long periods is not recommended, owing to its depressant action upon the central nervous system. The dried corm in powder may be **administered** in pills, or the drug may be prescribed as *Vinum Colchici* or *Extractum Colchici Siccum*. The use of hyoscyamus or belladonna with colchicum removes the tendency to intestinal irritation, since colchicum, like jaborandi, excites the vagal nerve endings in the gut and these same nerves are paralysed by atropine. Generally, preparations of colchicum corm are best given with a purge. In cases of **poisoning** by colchicum, the stomach should be emptied; atropine should then be given to eliminate the effect of colchicum on the alimentary canal. If there is much cerebral depression, injections of caffeine and sodium salicylate should also be given.

Dose.—Of the dried corm, 0·12 to 0·3 gramme (2 to 5 grains).

Preparations

Extractum Colchici Aceticum, B.P.C.—(*Ext. Colch. Acet.*)—Acetic Extract of Colchicum. An unstandardised soft extract prepared by evaporating the juice expressed from the fresh corm to which acetic acid has been added. **Dose.**—0·03 to 0·12 gramme ($\frac{1}{2}$ to 2 grains).

Extractum Colchici Siccum, B.P.—(*Ext. Colch. Sicc.*)—Dry Extract of Colchicum. *Syn.*—*Extractum Colchici*; *Extract of Colchicum*. It is prepared with alcohol (60 per cent.), concentration being effected under reduced pressure at a temperature not exceeding 60°. The product is dried at 100° and adjusted with lactose to contain 1 per cent. of colchicine (limits, 0·9 to 1·1); 0·06 gramme contains 0·0006 gramme, and 1 grain contains about $\frac{1}{16}$ grain. It should be stored in small, wide-mouthed, well-closed containers in a cool place. **Dose.**—0·016 to 0·06 gramme ($\frac{1}{4}$ to 1 grain).

Extractum Colchici I.A. is prepared from colchicum seed and contains 2 per cent. of colchicine.

Pilulæ Colchici et Aloes, B.P.C.—(*Pil. Colch. et Aloes*)—Colchicum and Aloes Pills. Each pill contains $\frac{1}{4}$ grain each of dry extract of colchicum, dry extract of hyoscyamus and aloes. **Dose.**—1 to 4 pills.

Pilulæ Colchici et Hydrargyri, B.P.C.—(*Pil. Colch. et Hydrarg.*)—Colchicum and Mercury Pills. Each pill contains $\frac{1}{8}$ grain of dry extract of colchicum, $\frac{1}{8}$ grain of pill of mercury and $\frac{1}{2}$ grain of compound extract of colocynth. **Dose.**—1 to 3 pills.

Pilulæ Colchici et Hydrargyri Compositæ, B.P.C.—(*Pil. Colch. et Hydrarg. Co.*)—Compound Colchicum and Mercury Pills. *Syn.*—*Brodie's Gout Pills*. Each pill contains $\frac{1}{2}$ grain of dry extract of colchicum and $1\frac{1}{2}$ grains each of pill of mercury, compound extract of colocynth and extract of rhubarb. **Dose.**—1 or 2 pills.

Vinum Colchici, B.P.C.—(Vin. Colch.)—Colchicum Wine. Colchicum corm, 1 in 5, macerated in sherry-type wine. Dose.—0·6 to 2 millilitres (10 to 30 minims).

This wine, prepared with sherry, was included in the British Pharmacopæia, 1914.

COLCHICI SEMEN

(Colch. Sem.)

Colchicum Seed

Colchicum seed consists of the dried ripe seeds of the meadow saffron, *Colchicum autumnale* Linn. (Fam. Liliaceæ), a plant widely distributed over Central and Southern Europe, and common in parts of England.

The seeds are sub-spherical, about 2 to 3 millimetres in diameter, and have a slight projection at the hilum, from which a strophiole extends for about one quarter of the circumference. The testa is reddish-brown, or somewhat paler, and is dull and rough from the presence of minute pits; the abundant endosperm is hard, slightly oily and yellowish; the embryo is small, straight, and placed radially near the outer surface. The seed is odourless, and has an unpleasant, bitter taste.

The diagnostic **microscopical** characters are the parenchyma of the testa, composed of cells with reddish-brown walls; the cells of the endosperm with thick, pitted, cellulose walls, and containing fixed oil and aleurone grains; the thin-walled parenchyma of the strophiole, containing ovoid to polyhedral starch grains about 5 to 20 microns in diameter.

Colchicum seed **contains** about 0·3 to 0·6 per cent. of the alkaloid, colchicine, which resides chiefly in the seed coats; it also contains sugar and fixed oil. The ash of colchicum seed is usually from 3 to 5 per cent.

Standard, B.P.—Colchicum seed contains not more than 2 per cent. of foreign organic matter and not less than 0·3 per cent. of colchicine. Ash, not more than 3 per cent.

Colchicum seed, in powder (Pulvis Colchici Seminis: Pulv. Colch. Sem.), contains the constituents and possesses the diagnostic microscopical characters of Colchici Semen, and complies with the limits for colchicine and ash of the unground drug. Pulvis Colchici I.A. is adjusted, if necessary, by dilution with rice starch to contain 0·4 per cent. of colchicine.

Action and Uses.—The physiological action and therapeutic properties of colchicum seed are similar to those of the corm (see Colchici Cormus). The seed is **administered** chiefly in the form of liquid extract or tincture. In cases of **poisoning** by colchicum seed, the procedure described under Colchici Cormus should be followed.

Dose.—0·12 to 0·3 gramme (2 to 5 grains).

COLCHICI FLOS.—Colchicum flower is the fresh perianth of the meadow saffron, *Colchicum autumnale* Linn., which blooms in the late summer; the flowers appear to spring directly from the ground, the plant having no leaves at this season. The six, petaloid, perianth parts are united to form a tube 7 to 8 centimetres long, whitish below, and expanding above into a funnel-shaped limb with six segments in two whorls. The oval-lanceolate segments are reddish-lilac or pale purple and about 3.5 to 5 centimetres long. To the inner surface of the perianth tube six stamens are attached. Colchicum flower contains about 0.1 per cent. of colchicine. It resembles the corm and the seed in its action, and has been used in the form of a tincture.

Preparations

Extractum Colchici Liquidum, B.P.—(Ext. Colch. Liq.)—Liquid Extract of Colchicum. *Syn.*—Fluidextractum Colchici. It is prepared with alcohol (60 per cent.) from defatted seeds, and adjusted to contain 0.3 per cent. w/v of colchicine (limits, 0.27 to 0.33); 0.3 millilitre contains about 0.0009 gramme and 5 minims contains about $\frac{7}{10}$ grain of colchicine. Dose.—0.12 to 0.3 millilitre (2 to 5 minims).

Tinctura Colchici, B.P.—(Tinct. Colch.)—Tincture of Colchicum. Liquid extract of colchicum, 10 per cent. v/v, in alcohol (60 per cent.). It contains 0.03 per cent. w/v of colchicine (limits, 0.027 to 0.033); 1 millilitre contains 0.0003 gramme and 15 minims contains about $\frac{2}{10}$ grain of colchicine. Dose.—0.3 to 1 millilitre (5 to 15 minims).

Tinctura Colchici I.A. is prepared with alcohol (70 per cent.) and contains 0.04 per cent. of colchicine.

Vinum Colchici Seminis, B.P.C.—(Vin. Colch. Sem.)—Colchicum Seed Wine. Colchicum seed, 1 in 10, macerated in detannated sherry-type wine. Dose.—0.6 to 2 millilitres (10 to 30 minims).

COLCHICINA

(Colchicin.)

Colchicine

Colchicine is an alkaloid obtained from the corm and seeds of *Colchicum autumnale* Linn. It occurs in the form of yellow flakes, crystals, or as a whitish-yellow amorphous powder, having a hay-like odour when damped and warmed, a very bitter taste, and darkening on exposure to light. An aqueous solution of colchicine is neutral to litmus, and lævorotatory. Melting-point, when dry, about 145°; when recrystallised from ethyl acetate, about 156°. It is a feeble base and is decomposed when warmed with dilute acids or alkalis, methyl alcohol and colchiceine being formed. It is extracted from acid solution by chloroform. From a solution in chloroform a compound of colchicine and chloroform is obtained by evaporation; in colchicine assays, the chloroform is removed by evaporation of the residue with alcohol. When a small quantity is dissolved in sulphuric acid and a little nitric acid added, a greenish-blue colour is produced, which changes through sky-blue to red and yellow; on the addition of sodium hydroxide the yellow solution becomes red. 0.05 gramme dissolved in 1 millilitre of dehydrated alcohol produces immediately a garnet-red

colour on the addition of one drop of ferric chloride solution. Colchicine should be **stored** in a dark place.

Soluble in water, alcohol and chloroform; very slightly soluble in ether; almost insoluble in light petroleum.

Standard.—Colchicine yields not more than 0.1 per cent. of ash. 0.01 gramme heated with 2 millilitres of sodium hydroxide solution and one drop of aniline does not develop the odour of phenyl isocyanide (limit of chloroform compound). 0.05 gramme dissolved in 5 millilitres of water produces no colour on the addition of ferric chloride solution (limit of colchicine), but, on heating, a brownish-red colour is produced.

Action and Uses.—Colchicine in large doses has a marked action on plain muscle, especially of the intestine, producing increased peristalsis and setting up diarrhœa and vomiting. Large doses produce, after a latent period of from one to three hours, a motor and sensory paralysis, ending in death from respiratory failure. Colchicine undergoes change to oxydicolchicine in the system. It first decreases and then increases the proportion of leucocytes in the blood, and excites karyokinesis in bone-marrow cells.

Colchicine is employed in acute gout; its action may be due to its effect upon the white corpuscles or to a corresponding stimulation of tissues of the body. It has no effect on the heart and circulatory system. Colchicine is occasionally **administered** in the form of solution, but solutions do not keep well, and in pills. The alkaloid is used in combination with methyl salicylate in capsules containing 0.25 milligram ($\frac{1}{250}$ grain) of the base or of colchicine salicylate. Solutions for **injection** may be sterilised by tyndallisation at 70° for one hour on three successive days, or by filtration. The containers should comply with the tests for limit of alkalinity of glass, and the solution should be protected from light. In cases of **poisoning** by colchicine, the procedure described under Colchici Cormus should be followed.

Dose.—0.0005 to 0.002 gramme ($\frac{1}{2000}$ to $\frac{1}{500}$ grain).

COLCHICINÆ SALICYLAS.—Colchicine salicylate, $C_{22}H_{25}O_6N, C_7H_6O_3$, occurs as a yellow, amorphous powder, soluble in water, alcohol and ether. It has been recommended in acute sciatica where there is a history of gout, in doses and in form similar to those of the alkaloid.

COLLINSONIA

(Collinson.)

Collinsonia

Synonyms—Stone Root; Knob Root.

Collinsonia is the rhizome of *Collinsonia canadensis* Linn. (Fam. Labiata), a plant indigenous to the United States of America and Canada.

The rhizome occurs in irregular, very hard, greyish-brown pieces, from 5 to 10 centimetres in length and 1 to 2 centimetres in diameter. The upper surface bears the remains of short, conical buds and conspicuous, shallow scars of aerial stems; on the under surface are short wiry roots or depressed scars of the same. The fracture is short; the transversely cut surface shows a wide, brown cork, a narrow cortex containing starch, and a large, whitish pith surrounded by a ring of thin, dark wedges of wood. The pith and very wide medullary rays are lignified and contain starch. The starch grains are simple, except a few which consist of two components, the simple grains being cylindrical, reniform, ovoid or oblong, and varying from about 3 to 38 microns in length. The drug is odourless and tasteless.

Collinsonia **contains** a saponin, resin, tannin, starch, mucilage and wax. It yields to alcohol (60 per cent.) about 10 per cent. of extractive.

Standard.—*Collinsonia* yields not more than 5 per cent. of ash.

Collinsonia, in powder (*Pulvis Collinsoniæ* : *Pulv. Collinson.*), contains the constituents of *Collinsonia*, and complies with the standard for the unground drug.

Action and Uses.—*Collinsonia* acts as an antispasmodic, and is employed in gastric and intestinal flatulence and in biliary colic. It is usually administered in the form of tincture.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

Preparation

Tinctura Collinsoniæ, B.P.C.—(*Tinct. Collinson.*)—Tincture of *Collinsonia*. 1 in 10. **Dose.**—2 to 8 millilitres ($\frac{1}{4}$ to 2 fluid drachms).

COLOCYNTHIS

(*Colocynth.*)

Colocynth

Synonyms—*Colocynthis Pulpa*; *Colocynth Pulp*; Bitter Apple.

Colocynth is the dried pulp of the fruit of *Citrullus Colocynthis* Schrad. (Fam. Cucurbitaceæ), a prostrate, herbaceous perennial, widely distributed throughout North Africa, Syria, Persia and North-West India, and cultivated in Spain and Cyprus. The fruit is collected when ripe, dried, and freed from the rind. The drug occurs in commerce in light, whitish balls about 5 centimetres in diameter, often more or less broken. The seeds, which constitute about 75 per cent. of the weight of the imported drug, are separated from the pulp by breaking the fruits and picking or sifting.

The dried pulp occurs in white or pale yellowish-white, light, pithy fragments. Very few seeds escape removal; they are about 7 millimetres long and 4.5 millimetres wide, and flattened-ovoid in shape;

the testa is yellowish-white to dark brown, smooth externally, and extremely hard; the seed is exalbuminous, and the embryo contains a large amount of fixed oil. The pulp is odourless and has an intensely bitter taste.

The diagnostic **microscopical** characters are the large, thin-walled, parenchymatous cells separated by intercellular spaces and showing flat, rounded, pitted areas where they are in contact; the occasional spiral and annular vessels; the absence of starch grains, crystals of calcium oxalate and of sclerenchymatous cells, excepting such small proportion as corresponds to an amount of seed not exceeding 5 per cent., and to an amount of outer sclerenchymatous part of the pericarp not exceeding 2 per cent.

Colocynth **contains** a bitter, amorphous, purgative alkaloid and amorphous, purgative resins; it also contains a small amount of an amorphous glycoside, and the following substances which are physiologically inactive:— α -elaterin, citrullol, hentriacontane, a phytosterol, and a mixture of fatty acids. The seeds contain about 15 per cent. of fixed oil, traces of an alkaloid, a phytosterol and an enzyme which hydrolyses β -glycosides.

Varieties.—Turkey colocynth, imported from Cyprus and Syria, consists of carefully peeled and unbroken fruits; it is white in colour and when cut transversely shows three large splits radiating from the centre, and six peripheral groups of seeds. Spanish colocynth resembles the Turkish variety but is usually more or less discoloured and less carefully peeled. Egyptian colocynth, from the Anglo-Egyptian Sudan, is generally in broken pieces, but of good colour. The seeds must be removed before use.

Standard, B.P.—Colocynth contains not more than 5 per cent. of the seeds and not more than 2 per cent. of the outer sclerenchymatous part of the pericarp. Acid-insoluble ash, not more than 8 per cent. By continuous extraction with light petroleum (boiling-point, 50° to 60°), it yields not more than 3 per cent. of soluble matter dried at 100°.

Colocynth, in powder (*Pulvis Colocynthis* : *Pulv. Colocynth.*), contains the constituents and possesses the diagnostic microscopical characters of *Colocynthis*, and complies with the limits for acid-insoluble ash and matter soluble in light petroleum of the unground drug.

Action and Uses.—Colocynth is a powerful hydragogue cathartic; it is rarely used alone on account of its drastic nature, but is an important ingredient of *Extractum Colocynthis Compositum*, *Pilulæ Colocynthis Compositæ* and *Pilula Colocynthis et Hyoscyami*. Colocynth principles are partly absorbed, and excreted in the urine and milk. Colocynth is extremely irritant, severe pain being caused when the powdered drug is applied to the nostrils. A simple tincture of colocynth (*Tinctura Colocynthis*, 1 in 10) has been used in mixture form with the tinctures of podophyllum and belladonna. In cases of **poisoning** by colocynth, the stomach should be emptied, opium given by mouth or rectum, followed by stimulants and demulcent drinks.

Dose.—0.12 to 0.3 gramme (2 to 5 grains).

Preparations

Extractum Colocynthis Compositum, B.P.—(Ext. Colocynth. Co.)—Compound Extract of Colocynth. It contains aloes, scammony resin, curd soap and cardamom, mixed with an extract prepared by macerating colocynth in alcohol (60 per cent.) and evaporating to dryness the liquid thus obtained. Dose.—0·12 to 0·5 gramme (2 to 8 grains).

Pilulæ Colocynthis Compositæ, B.P.C.—(Pil. Colocynth. Co.)—Compound Pills of Colocynth. *Syn.*—Pil. Cochia. Each pill contains $\frac{3}{4}$ grain of colocynth, $1\frac{1}{2}$ grains each of aloes and scammony resin, with curd soap and oil of clove. Dose.—1 or 2 pills.

The mass with which these pills are made contains approximately the same relative proportions of active ingredients as Pilula Colocynthis Composita of the British Pharmacopœia, 1914, which was prepared with colocynth, 20 grammes; aloes, 35 grammes; scammony resin, 35 grammes; potassium sulphate, 5 grammes; oil of clove, 5 millilitres; distilled water, a sufficient quantity.

Pilulæ Colocynthis et Hydrargyri, B.P.C.—(Pil. Colocynth. et Hydrarg.)—Colocynth and Mercury Pills. Each pill contains 2 grains of compound extract of colocynth and 3 grains of pill of mercury. Dose.—1 or 2 pills.

Pilulæ Colocynthis et Hydrargyri Compositæ, B.P.C.—(Pil. Colocynth. et Hydrarg. Co.)—Compound Colocynth and Mercury Pills. Each pill contains $\frac{3}{4}$ grain of pill of colocynth and hyoscyamus and $\frac{1}{4}$ grain of pill of mercury. Dose.—1 to 4 pills.

Pilula Colocynthis et Hyoscyami, B.P.—(Pil. Colocynth. et Hyoscy.)—Pill of Colocynth and Hyoscyamus. Colocynth, about 12·5 per cent., aloes and scammony resin, of each about 25 per cent., with curd soap, oil of clove, dry extract of hyoscyamus and syrup of liquid glucose. Dose.—0·25 to 0·5 gramme (4 to 8 grains).

Pilulæ Hydrargyri Subchloridi, Colocynthis et Hyoscyami, B.P.C.—(Pil. Hydrarg. Subchlor. Colocynth. et Hyoscy.)—Mercurous Chloride, Colocynth and Hyoscyamus Pills. *Syn.*—Calomel, Colocynth and Hyoscyamus Pills; Zittmann's Pills. Each pill contains 1 grain of mercurous chloride, $2\frac{1}{2}$ grains of compound extract of colocynth and 1 grain of dry extract of hyoscyamus. Dose.—1 or 2 pills.

Pilulæ Hydrargyri Subchloridi et Colocynthis, B.P.C.—(Pil. Hydrarg. Subchlor. et Colocynth.)—Mercurous Chloride and Colocynth Pills. *Syn.*—Calomel and Colocynth Pills. Each pill contains 1 grain of mercurous chloride and 4 grains of compound extract of colocynth. Dose.—1 pill.

Tabellæ Leptandræ Compositæ, B.P.C.—(Tab. Leptand. Co.)—Compound Tablets of Leptandra. *Syn.*—Tabellæ Laxativæ Compositæ; Vegetable Laxative Tablets. Each tablet contains 1 grain of compound extract of colocynth and $\frac{1}{4}$ grain each of jalap resin, resin of podophyllum, dry extract of hyoscyamus, extract of taraxacum and extract of leptandra, and oil of peppermint. Dose.—1 to 3 tablets.

COLOPHONIUM

(Coloph.)

Colophony

Synonyms—Resina; Resin; Rosin; Amber Resin.

Colophony is the residue left after the removal, by distillation, of the

oil of turpentine from the crude oleo-resin obtained from *Pinus palustris* Mill., *P. tæda* Linn. and other species of *Pinus* (Fam. Pinaceæ), trees growing in Europe and the United States of America. Although the trees normally contain schizogenous resin ducts, these are sufficient to yield only a very small amount of oleo-resin, the bulk of which is produced by hacking the trees so as to wound the young wood; the new wood formed in the region of the injury is very liberally supplied with oleo-resin ducts, from which the secretion flows abundantly over the wounded area and is collected either in a cavity or "box" cut in the base of the tree trunk, or in receptacles attached to the tree below the wounded area. The crude oleo-resin is distilled with water, the oil of turpentine passing over and the resin remaining in the still.

Colophony occurs in transparent, pale yellow or brownish-yellow, angular, brittle masses, which are readily fusible and have a faint terebinthinate odour and taste. On the addition of one drop of sulphuric acid to 10 millilitres of a 1 per cent. solution of colophony in acetic anhydride, a bright purplish-red colour is produced which rapidly changes to violet. When a filtered 1 per cent. solution of colophony in light petroleum is shaken with twice its volume of dilute copper acetate solution, the light petroleum layer assumes a bright bluish-green colour. Colophony is **soluble** in alcohol (90 per cent.), ether, benzene and carbon disulphide; partially soluble in light petroleum; insoluble in water.

Colophony appears to **contain** three isomeric abietic acids (α , β , and γ), together with a small quantity (5 to 6 per cent.) of a resene, traces of volatile oil, and a bitter principle. Crystalline colophenic acids have also been isolated from it. The resin acids appear to undergo change (probably oxidation) when exposed to the air, and become less soluble in light petroleum. The exact composition is still a matter of uncertainty.

Substitutes.—Black resin is the resin obtained from the later runnings from the incisions into the trees or it may be formed by long continued application of heat to the amber-coloured colophony. If the water is not entirely removed during the process an opaque resin results.

Standard, B.P.—Colophony has an acid value ranging from 150 to 180. Ash, not more than 0.1 per cent.

Colophony, in powder (Pulvis Colophonii : Pulv. Coloph.), complies with the standard for the unground drug.

Action and Uses.—Colophony was formerly given internally for rheumatism, sometimes with guaiacum resin. It is partly absorbed, and excreted in the urine; during excretion it excites the kidneys to diuresis. Sometimes so much is excreted in the urine that nitric acid causes a precipitate of the resin, simulating albumin; the precipitate is readily distinguished from albumin in that it is soluble in alcohol. Emplastrum Colophonii is used as an adhesive plaster in minor surgery for strapping wounds. Unguentum Colophonii is applied as a stimulant to indolent ulcers and boils.

Preparations

Emplastrum Colophonii, B.P.—(Emp. Coloph.)—Plaster of Colophony. *Syn.*—Emplastrum Resinæ; Resin Plaster; Adhesive Plaster. Colophony, 10 per cent., and hard soap, 5 per cent., in plaster of lead.

Resina Carbolisata, B.P.C.—(Res. Carbol.)—Carbolised Resin. Phenol, 1 part; mastic, 1 part; colophony, 2 parts; chloroform, 1 part.

Unguentum Colophonii, B.P.C.—(Ung. Coloph.)—Colophony Ointment. *Syn.*—Unguentum Resinæ; Resin Ointment; Yellow Basilicon Ointment. Colophony, 26 per cent., with yellow beeswax, olive oil and lard.

This ointment was included in the British Pharmacopœia, 1914, under the name of Unguentum Resinæ.

CONDURANGO

(Conduran.)

Condurango

Condurango is the bark obtained from the stem of *Marsdenia Condurango* Nichols (Fam. Asclepiadaceæ), a climbing plant indigenous to Ecuador. The bark is removed by beating the stem with a mallet, and dried in the sun.

The bark occurs in quilled or curved pieces about 5 to 10 centimetres long, 0.5 to 2.0 centimetres wide and 2 to 6 millimetres thick. Externally is a thin, greyish-brown cork, often warty, and sometimes scaly. The inner surface is paler and coarsely striated. The fracture is short and somewhat fibrous. The smoothed, transverse surface is pale and shows a few scattered groups of sclereids. The taste is bitter and somewhat acrid, but the odour is slight.

The diagnostic **microscopical** characters are the phelloderm cells containing prismatic crystals of calcium oxalate; rosette crystals in the rest of the tissues; clusters of pitted stone cells scattered in the cortex and phloem; laticiferous vessels throughout the bark.

The bark **contains** the poisonous glycoside, or mixture of glycosides, known as condurangin, together with a crystalline resin-ester and traces of fat and volatile oil. Aqueous solutions of condurangin coagulate or become cloudy when heated and clear again on cooling. Decoctions of condurango should, therefore, be strained when cold. This property has been shown to be due to the presence of water-soluble salts, and when these are removed solutions of condurangin remain clear when boiled. Condurangin has been considered to be identical with vinetoxin. The ash of the bark is about 9 per cent.

Action and Uses.—Condurango has been **administered** as a gastric sedative in the form of a liquid extract (Extractum Condurango Liquidum, 1 in 1), and as a wine (Vinum Condurango, 1 of liquid extract to 9 of detannated sherry).

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

CONII FOLIUM

(Conii Fol.)

Conium Leaf*Synonym*—Hemlock Leaf.

Conium leaf consists of the fresh, leafy tops of *Conium maculatum* Linn. (Fam. Umbelliferæ), an annual or biennial herbaceous plant distributed throughout Europe and Great Britain. The leaves and young branches are collected when the fruit is beginning to form.

The leaves are tripinnate and glabrous; the ultimate divisions are ovate or lanceolate, with serrate margins, and terminate in smooth, colourless points. The leaves are attached by amplexicaul petioles to smooth, hollow stems marked with purplish spots. The inflorescence is a compound umbel with ten to twenty rays; the general involucre has three to seven bracts; the partial involucre has three outwardly-directed, lanceolate bracts which are shorter than the partial umbels. The fruit is a cremocarp with crenate ridges and deeply grooved endosperm. The odour is nauseous and mouse-like, and is accentuated by the action of caustic alkali; the taste is bitter.

Conium leaf **contains** the alkaloids, coniine (conine), γ -coniceine and conhydrine; the stem contains about 0.05 per cent. of total alkaloids, the leaves about 0.2 per cent., and the flowers and flower-stalks about 0.25 per cent. Conium also contains methylconiine and pseudoconhydrine.

Adulterants.—Conium leaf is liable to adulteration with the leaves and young branches of other indigenous umbelliferous plants, such as wild chervil, *Anthriscus sylvestris* Hoffm., and fool's parsley, *Aethusa Cynapium* Linn. Wild chervil is distinguished by its hairy leaves; fool's parsley by the absence of a general involucre of bracts, the three long narrow bracts of the involuclers, and the ultimate divisions of the leaves which terminate in short, brownish points.

Action and Uses.—Conium leaf has been used internally as a sedative and antispasmodic in the form of Succus Conii, or as Extractum Conii in pills or suppositories. Externally, Unguentum Conii is a soothing application to hæmorrhoids and other irritable conditions of the rectum. In cases of **poisoning** by conium leaf, the antidotes described under Coniina should be employed.

Dose.—0.12 to 0.5 gramme (2 to 8 grains).

Preparations

Extractum Conii, B.P.C.—(Ext. Conii)—Extract of Conium. *Syn.*—Extract of Hemlock. A soft extract prepared from the juice expressed from conium leaf. Dose.—0.12 to 0.4 gramme (2 to 6 grains).

Succus Conii, B.P.C.—(Succ. Conii)—Juice of Conium. *Syn.*—Juice of Hemlock. The juice expressed from conium leaf, mixed with one-third its volume of alcohol (90 per cent.). Dose—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Unguentum Conii, B.P.C.—(Ung. Conii)—Ointment of Conium. *Syn.*—Hemlock Ointment. Extract of conium, 7 per cent., in glycerin and simple ointment.

CONII FRUCTUS

(Conii Fruct.)

Conium Fruit*Synonym*—Hemlock Fruit.

Conium fruit consists of the dried, unripe fruits of *Conium maculatum* Linn. (Fam. Umbelliferæ), a plant distributed throughout Europe and Great Britain. The fruits are collected and dried when fully grown, but before they are ripe. They deteriorate with age and should not be used when more than two years old.

The fruits are greenish-grey in colour, and about 3 millimetres in length and breadth. In shape, the cremocarps are broadly ovoid, slightly compressed laterally and crowned with small stylopods. The separate mericarps are quite glabrous and marked with five irregularly crenate, primary ridges. The fruits have no marked odour or taste, but develop a strong, disagreeable, mouse-like odour when triturated with potassium hydroxide solution; this odour is, however, not strong enough for the detection of small admixtures of conium with other fruits. A transverse section through the fruit shows the endosperm to be deeply grooved on the commissural surface; vittæ cannot be seen with a lens, although vestiges may be found by careful microscopical examination.

Conium fruit **contains** as much as 2·5 per cent. of alkaloids, consisting mainly of coniine, if gathered when fully grown but still unripe. Parcels containing considerable proportions of ripe fruits may yield less than 1 per cent., and carelessness in collection, or too lengthy storage, may reduce the percentage to less than 0·1. The subsidiary alkaloids are conhydrine, γ -coniceine, methylconiine and pseudo-conhydrine.

Standard.—Conium fruit contains not more than 2 per cent. of foreign organic matter. Ash, not more than 7 per cent.

Action and Uses.—Conium fruit is used principally as a source of coniine, although preparations of it may be used internally as sedatives or antispasmodics. In cases of **poisoning** by conium fruit, the antidotes described under Coniina should be employed.

CONIINA .

(Coniin.)

Coniine*Synonyms*—Conine; Cicutine.

Coniine, or *d*- α -propylpiperidine, $\text{C}_8\text{H}_{17}\text{N}$ (C_3H_7), is a liquid alkaloid found in all parts of *Conium maculatum* Linn., but more especially in the immature fruit, in combination with malic acid. It may

be obtained by distilling the crushed seeds with weak solution of potassium hydroxide, neutralising the distillate, evaporating the solution to dryness, adding excess of alkali to the alkaloidal salt, extracting the base thus liberated with ether, and, finally, purifying by distillation. The product is a mixture of hemlock alkaloids in which *d*-coniine predominates. Racemic coniine may be prepared synthetically by the action of sodium on an alcoholic solution of allylpyridine, which is a liquid product of the action of paraldehyde on picoline.

Coniine occurs in the form of an almost colourless liquid with a penetrating, mouse-like odour and an acrid taste; it is volatile and dextrorotatory, and becomes brown on exposure to the air. The aqueous solution has an alkaline reaction. The base takes up 25 per cent. of water, and the cold, saturated solution becomes turbid on warming. Specific gravity, about 0.863 at 0° and about 0.844 at 19°. Boiling-point, about 166°. On cooling, it solidifies to a crystalline mass, which melts at -2°. It is a powerful base, and unites with acids to form stable crystalline salts. With concentrated sulphuric acid it gives first a blood-red and then a green colour. Cadmium iodide yields an amorphous precipitate, distinguishing it from nicotine, which yields a crystalline precipitate. Coniine, unlike nicotine, is not precipitated by platinic chloride. A further distinguishing test is to add 1 drop of a concentrated alcoholic solution of phenolphthalein to a solution of the base; with coniine a red colour is developed, but with nicotine there is no reaction.

Soluble in water (1 in 100), alcohol, ether, chloroform, benzene, amyl alcohol and acetone.

Action and Uses.—Coniine depresses the medulla and the motor nerve-endings, so that after large doses death results from respiratory paralysis, which is mainly central—that is, the medulla is paralysed before the nerves. On the circulatory system, coniine resembles nicotine, in action in that it paralyses autonomic nerve-cells after an initial stimulation, and so lowers blood pressure by paralysis of the splanchnics, and quickens the heart by paralysis of the vagi. It has been used in chorea, mania, paralysis agitans, tetanus, and strychnine poisoning for its depressant action on the motor nerves, but in this respect is inferior to curare. It is also employed in spasmodic affections such as laryngismus, whooping cough and asthma. To allay cough and bronchial spasm it is best given as an inhalation. **Externally**, it is sedative and specially valuable in pruritus ani, and for the relief of the pain of fissures and ulcerated hæmorrhoids.

The alkaloid is rarely administered, coniine hydrobromide or hydrochloride being preferred. In cases of **poisoning** by coniine or its salts, the stomach should be emptied, and stimulants and warmth applied, with artificial respiration if necessary. As an antidote, strong tea or 1 to 1.2 grammes (15 to 20 grains) of tannic acid in aqueous solution should be given.

Dose.—0.001 to 0.01 gramme ($\frac{1}{100}$ to $\frac{1}{10}$ grain).

CONIINÆ HYDROBROMIDUM.—Coniine hydrobromide, $C_8H_{17}N, HBr$, a salt of the base with hydrobromic acid, occurs in the form of colourless, transparent, glistening, rhombic crystals, or as a white, crystalline powder, melting at about 212° . It is soluble in water (1 in 2), alcohol (1 in 3), or in ether-alcohol, but insoluble in ether. The solutions are colourless and neutral. Coniine hydrobromide may be administered in pills or in syrup. Pessaries may be prepared with a glyco-gelatin basis and contain $\frac{1}{2}$ grain of coniine hydrobromide. Dose.—0.004 to 0.016 gramme ($\frac{1}{20}$ to $\frac{1}{4}$ grain).

CONIINÆ HYDROCHLORIDUM.—Coniine hydrochloride, $C_8H_{17}N, HCl$, a salt of the base with hydrochloric acid, occurs in the form of colourless crystals, soluble in water, alcohol, or chloroform. Melting-point, about 220° . Coniine hydrochloride is used in the same manner as the hydrobromide.

CONVALLARIA

(Convallar.)

Convallaria

Synonyms—Convallaria Flowers; Lily of the Valley Flowers.

Convallaria consists of the dried inflorescence of *Convallaria majalis* Linn. (Fam. Liliaceæ), a small herbaceous plant indigenous to Britain and widely distributed over Europe, North America and Northern Asia.

The scape is about 20 centimetres long, about 2 millimetres wide at the base, and tapers towards the apex; it is semi-circular in transverse section, the flattened side appearing in the drug as a longitudinal, shallow groove. Upon the upper part of the scape are from about 3 to 8 pale brown, shrivelled flowers, each attached to a slender pedicel about 8 millimetres long and arising in the axil of a small, scarious, lanceolate bract. The perianth is from about 4 to 5 millimetres in length and breadth; it has 6 recurved teeth, and bears 6 stamens on its inner surface; the ovary is superior and tri-locular. The odour is slight and pleasant; the taste is at first sweetish and then bitter and slightly acid. The drug yields to alcohol (60 per cent.) about 30 per cent. of extractive. The ash is about 10 per cent.

Convallaria contains two crystalline glycosides, convallamarin, $C_{23}H_{44}O_{12}$, and convallarin, $C_{34}H_{62}O_{11}$. Convallamarin has a bitter taste.

Action and Uses.—Convallaria has an action similar to that of digitalis, and is used chiefly in the form of tincture.

CONVALLARIÆ RHIZOMA.—Dried convallaria rhizome is of varying length and about 3 millimetres thick. It is whitish or pale brown, cylindrical, wrinkled, and marked with circular scars. The nodes are annulated and bear long, thin, tortuous branched roots or scars where they have been detached. The fracture is fibrous and the interior white in colour. Odour, slight; taste, at first sweet, becoming bitter and slightly acid.

Preparations

Extractum Convallaræ Liquidum, B.P.C.—(Ext. Convallar. Liq.)—Liquid Extract of Convallaria. 1 in 1. Dose.—0.3 to 0.6 millilitre (5 to 10 minims).

Tinctura Convallaræ, B.P.C.—(Tinct. Convallar.)—Tincture of Convallaria. 1 in 8. Dose.—0.3 to 1.2 millilitres (5 to 20 minims).

COPAIBA

(Copaib.)

Copaiba*Synonym*—Balsam of Copaiba.

Copaiba is the oleo-resin obtained from the trunk of *Copaifera Lansdorfii* Desf. and other species of *Copaifera* Linn. (Fam. Leguminosæ), large trees indigenous to Brazil and the north of South America. The oleo-resin is secreted in schizogenous ducts which subsequently form large lysigenous cavities in the trees; it is collected by boring into the base of the trunk and allowing to drain out. It occurs as a more or less viscous, yellow to golden-brown liquid, which is generally transparent and sometimes fluorescent. The various commercial varieties are named after the towns from which they are exported, and differ somewhat in appearance and composition. The most important are known as Pará, Maranh, Maracaibo and Savanilla. Pará copaiba is a thin, transparent, yellowish liquid, and contains a high percentage of volatile oil. Maracaibo copaiba is viscous, brownish-yellow and slightly fluorescent. Copaiba has a characteristic odour and a persistent, slightly bitter, acrid taste.

Copaiba **contains** varying proportions of volatile oil and resin. The resin obtained by heating the balsam in a shallow dish until the oil has been completely dissipated, is a hard, brittle mass which consists chiefly of amorphous resin-acids accompanied by a small quantity of crystalline resin-acids and indifferent resenes, the nature of these constituents varying in different varieties.

Miscible in all proportions with dehydrated alcohol, ether, carbon disulphide, fixed and volatile oils; miscible with an equal volume of light petroleum (boiling-point, 50° to 60°), the addition of a further quantity of the solvent producing a flocculent precipitate.

Standard, B.P.—Copaiba has a specific gravity of 0.960 to 0.995. Acid value, calculated with reference to the residue obtained by drying on a water-bath, 120 to 160. Optical rotation of the volatile oil obtained by distillation with steam, or under reduced pressure, -7° to -35° . Residue on evaporation on a water-bath, not less than 50 per cent. and not more than 65 per cent. No odour of turpentine is observed during the evaporation, and the residue is hard and brittle when cold. It complies also with tests for absence of gurgun balsam and fatty oils.

Action and Uses.—Copaiba is carminative and antiseptic, and is used for its effects during excretion by the bronchioles, skin and kidneys. It is eliminated in the urine, which then gives the test for albumin with nitric acid by the precipitation of the resin-acids. It is especially used in chronic inflammation of the genito-urinary tract for its mildly stimulant action upon the inflamed mucous membrane and for its antiseptic properties. In chronic bronchitis, especially where there is much expectoration, it is of value. It may produce a rash, and its continued use tends to cause irritation of the gastric mucous membrane.

On account of its disagreeable taste copaiba is commonly administered in gelatin capsules. Emulsions of copaiba may be prepared with solution of potassium hydroxide which dissolves the resin, or with mucilage of acacia. Miscible solutions are prepared from copaiba, alone or combined with sandal wood oil cubeb, and buchu.

Dose.—0·6 to 2 millilitres (10 to 30 minims).

AFRICAN COPAIBA is obtained from an unknown botanical source and is imported from West Africa. It occurs as a dark yellow, slightly fluorescent oleo-resin, with an aromatic odour. Specific gravity, 0·985 to 1·000. It contains about 40 per cent. of a dextrorotatory volatile oil.

GURJUN BALSAM, or wood oil, is an oleo-resin obtained from *Dipterocarpus turbinatus* Gaertn. (Fam. Dipterocarpaceæ) and other species, large trees indigenous to Eastern India and Burma. It resembles copaiba in odour and taste, but is usually somewhat darker. It contains from 40 to 80 per cent. of volatile oil.

Preparations

Liquor Copaibæ, B.P.C.—(Liq. Copaib.)—Solution of Copaiba. *Syn.*—Soluble Copaiba. Copaiba, 1 in 2, dissolved in a solution of potassium hydroxide. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Liquor Copaibæ, Buchu et Cubebæ, B.P.C.—(Liq. Copaib. Buchu et Cubeb.)—Solution of Copaiba, Buchu and Cubeb. Solution of copaiba, 4 in 5, with liquid extracts of buchu and cubeb. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Liquor Copaibæ, Buchu et Cubebæ cum Oleo Santali, B.P.C.—(Liq. Copaib. Buchu et Cubeb. c. Ol. Santal.)—Solution of Copaiba, Buchu and Cubeb with Sandal Wood Oil. Oil of sandal wood, 1 in 10, and oil of cassia, 1 in 20, with solution of copaiba, buchu and cubeb, and alcohol (90 per cent.). Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Liquor Copaibæ et Olei Santali, B.P.C.—(Liq. Copaib. et Ol. Santal.)—Solution of Copaiba and Sandal Wood Oil. Solution of copaiba, 4 in 5, with oils of sandal wood and cassia, and alcohol (90 per cent.). Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

COPAL

(Copal)

Copal

Synonyms—Zanzibar Copal; Gum Animi.

Copal is a fossil resin obtained from *Trachylobium Hornemannianum* Hayne (Fam. Leguminosæ), found on the coast of East Africa. It is dug up by the natives and brought to Zanzibar, where it is prepared for the market by cleaning and sorting.

The resin occurs in pieces of very varying size and of pale yellow to deep reddish-brown or greenish-red colour. It is usually transparent or semi-transparent, the surface being warty, longitudinally striated, or smooth. Copal consists chiefly of trachyloic acid (80 per cent.), associated with *isotrachyloic* acid (4 per cent.), and copal resenes

(6 per cent.), together with volatile oil, a bitter principle, etc. Specific gravity, about 1.06.

Copal is entirely **soluble** in alcohol, but only partially in benzene, chloroform, glacial acetic acid, ether and oil of turpentine.

Varieties.—The term copal has been applied to a number of different resins, chiefly of fossil, but some of recent, origin. They are the product of very different plants, and have been obtained from different parts of the world. The chief and most important is Zanzibar copal, as described above. American copal, imported from Brazil and obtained from *Hymenaea Courbaril* Linn., is pale brown, transparent, brittle, and of agreeable odour. Specific gravity, 1.028 to 1.082. Australian copal, or gum kauri, is obtained from *Agathis australis* Steud., a tree growing in northern New Zealand. The greater part of the exported resin is fossil, and occurs in large pieces, of a pale yellow or greenish-yellow colour, with a conchoidal, vitreous fracture and a balsamic odour. Specific gravity, 1.062 to 1.109 or even higher. The finer specimens are occasionally used as amber substitutes. East Indian dammar is sometimes called Manila copal (see Dammar). West African copal is obtained from *Copaifera Guibourtiana* Benth.

Uses.—Copal is used principally in the manufacture of varnishes. For this purpose it is heated until frothing ceases, when linseed oil is added, the mixture again heated to about 260° and the thick liquid so produced dissolved in oil of turpentine. Under the name Gum Animi, it is occasionally ordered as an ingredient of plasters.

DAMMARA.—Dammar is a generic term for a number of different resins, of which East Indian or Singapore dammar is the only one that appears on the English market in quantity. East Indian dammar is derived from species of *Shorea*, *Hopea* and *Balanocarpus* (Fam. Dipterocarpaceæ), which are cultivated in the Eastern Archipelago. Dammar occurs in nodules 3 to 6 millimetres in diameter, but sometimes larger; the exterior is coated with white powder, while the interior is pale amber-coloured, transparent or translucent. It is readily friable and adheres only feebly on warming in the hand. It softens at about 100°, melts at about 150° to a clear liquid and ignites with difficulty. The fracture is conchoidal and vitreous, and usually exhibits air bubbles and vegetable debris. The odour is balsamic when the resin is fresh, but afterwards imperceptible. Specific gravity, 1.062 to 1.123. The yield of ash on ignition should be almost infinitesimal. Dammar is sometimes known as Manila copal or mastic. Rock dammar, obtained from *Shorea* species, is sometimes imported and closely resembles the above, but may be distinguished by its insolubility in 60 per cent. aqueous solution of chloral hydrate, in which all coniferous resins are soluble. Kauri resin is sometimes called New Zealand dammar (see Copal). Dammar is partly soluble in cold alcohol, moderately soluble in ether, soluble in boiling alcohol, fixed oils, oil of turpentine and other volatile oils, chloroform, carbon disulphide and light petroleum. Dammar consists mainly of a mixture of resenes (about 20 per cent.) and resin-acids, and also contains small quantities of a bitter principle and a volatile oil. The principal use of dammar is in the preparation of varnishes, but it is occasionally used as a constituent of plaster masses and as a microscopical mountant.

VENICE TURPENTINE.—Venice turpentine is the oleo-resin collected in South Tyrol from the larch, *Larix europea* DC. (Fam. Pinacæ). A hole is bored into the trunk of the tree and the oleo-resin gradually fills the cavity. It is a viscous, yellowish, turbid fluid, entirely soluble in dehydrated alcohol. It does not harden readily on exposure to the air or when mixed with one-sixteenth of its weight of magnesia. It contains α - and β -linolic acids (55 to 60 per cent.), resene (14 per cent.) and a volatile oil resembling turpentine (15 to 20 per cent.). The Venice turpentine of commerce is often a factitious substance prepared by dissolving colophony in oil of turpentine; it is darker in colour than the genuine substance. Venice turpentine is used in veterinary practice.

CORIANDRUM

(Coriand.)

Coriander*Synonyms*—Coriandri Fructus; Coriander Fruit.

Coriander consists of the dried, ripe fruits of *Coriandrum sativum* Linn. (Fam. Umbelliferæ), an erect, herbaceous annual, indigenous to Southern Europe and naturalised throughout temperate Europe. It is cultivated chiefly in Russia, Central Europe, Northern Africa and India. The plant is cut when the fruits are ripe, and threshed.

The sub-globular cremocarps are from about 2 to 4 millimetres in diameter and are usually entire; they are glabrous, brownish-yellow or with a slight rose-tint; at the apex is a small stylopod and the remains of the calyx teeth; on each mericarp there are four straight, secondary ridges and five less conspicuous, undulating, primary ridges. The transversely cut surface shows in the dorsal part of the pericarp a continuous band of lignified sclerenchyma and, on the commissure, two, or rarely more, large vittæ; the oily endosperm is concave on the commissural surface. The drug has an aromatic odour and an agreeable, spicy taste.

The diagnostic **microscopical** characters are the lignified sclerenchyma of the mesocarp consisting of crossing layers of sinuous rows of pitted fusiform cells; the endosperm, composed of thick-walled, polygonal, cellulosic parenchyma containing fixed oil, aleurone grains and minute rosettes of calcium oxalate; the outer epidermis of the pericarp showing stomata and occasional prisms of calcium oxalate, although this epidermis may have been thrown off, exposing the inner parenchyma consisting of elongated, thin-walled, collapsed cells.

Coriander **contains** about 1 per cent. of volatile oil.

Standard, B.P.—Coriander contains not more than 2 per cent. of foreign organic matter. Ash, not more than 7 per cent. Acid-insoluble ash, not more than 1 per cent.

Coriander, in powder (Pulvis Coriandri : Pulv. Coriand.), contains the constituents and possesses the diagnostic microscopical characters of Coriandrum, and complies with the limits for ash and acid-insoluble ash of the unground drug.

Action and Uses.—The aromatic and carminative properties of coriander render it a suitable substance for addition to purgative medicines to prevent griping.

Dose.—0.3 to 1 gramme (5 to 15 grains).

CORPUS LUTEUM

(Corp. Lut.)

Corpus Luteum

Synonyms—Corpus Luteum Siccum; Desiccated Corpus Luteum. Corpus luteum is the material obtained by cleaning, drying and

powdering the corpora lutea taken from the ovaries of cows and sows. It occurs in the form of a brown powder for which tests for identity and purity have not yet been worked out. The corpus luteum is the yellow body which is formed in the cavity of the Graafian follicle after ovulation; it is composed of large, glandular cells containing lutein granules. The yellow colour is due to carotene. The corpora lutea of cows are often hollow and enclose a viscous fluid which contains oestrin. The corpus luteum is believed to secrete a hormone termed progesterin, corporin, or lutein. The secretion of progesterin inhibits oestrus, menstruation and ovulation during pregnancy, and causes thickening of the mucous membrane lining the uterus, in preparation for the embedding of the ovum. Progesterin is slightly soluble in water, soluble with decomposition in alkalis, soluble in acetone, methyl alcohol, ethyl alcohol, ether, light petroleum and chloroform. It differs from ketohydroxyoestrin in its instability in alkalis. A second substance termed relaxin has also been obtained from corpora lutea of cows by extraction with acidified water. It is soluble in water, insoluble in acetone, ether, light petroleum and dehydrated alcohol; it is destroyed by heating above 50°, by formaldehyde, and by proteolytic enzymes. When injected into virgin guinea pigs during oestrus, it produces marked relaxation of the pelvic ligaments.

Action and Uses.—The action of corpus luteum given by the mouth is uncertain. It is prescribed in some cases of menorrhagia and hyperemesis gravidarum, and to prevent abortion. It may be administered in doses of 0.06 to 0.3 gramme (1 to 5 grains) of the desiccated powder in capsules or tablets. For intramuscular injection, 1 millilitre of a solution containing 0.02 gramme of soluble extract (equivalent to 0.06 to 0.18 gramme of corpus luteum), with sodium chloride, and chlorbutol as a preservative, may be administered at intervals of from one to four days. The effects of corpus luteum administration can often be obtained more satisfactorily by the use of the anterior pituitary-like hormone derived from urine of pregnancy.

CORYDALIS

(Coryd.)

Corydalis

Corydalis consists of the dried tubers of *Dicentra canadensis* Walp. (Squirrel Corn, Turkey Corn) and of *D. Cucullaria* Bernh. (Dutchman's Breeches) (Fam. Papaveraceæ), plants growing in the North-Eastern United States of America.

The drug is usually a mixture of the tubers from the two plants; those of *D. canadensis* occur singly and are spheroidal, being about 5 to 8 or up to 16 millimetres wide, and 3 to 5 or up to 8 millimetres high; the upper surface shows a slight depression with a scar, and the lower

surface is somewhat flattened, and has attached to it the dried remains of the very small, knotty rhizome; the almost smooth surface is minutely pitted or wrinkled and varies in colour from yellowish-grey to brownish-black, the lighter coloured tubers being somewhat translucent; the smoothed, transverse surface is yellowish in colour and starchy. The tubers of *D. Cucullaria* differ from those of *D. canadensis* by occurring in groups of about 3, attached to a small rhizome; in the drug, the groups are usually separated into individual tubers, which are about 1·5 to 5 or up to 12 millimetres wide, and 3 to 6 or up to 12 millimetres high; they are ovoid or ovoid with a flat side, or very broadly triangular-ovoid and have an acute apex, and the larger ones have the very small, knotty rhizome attached below. The drug has no odour and a very slightly bitter taste.

The diagnostic **microscopical** characters are the straight-walled epidermal cells; the lignified stone cells of various shapes, isodiametric or elongated, isolated or in groups of 2 to 4, and up to about 75 microns long; the starch grains, which are ovoid or ovoid-oblong, with striations and a hilum at the narrower end, 3 to 60 microns long; the very few small cluster-crystals of calcium oxalate.

The tubers of *D. canadensis* **contain** protopine, bulbocapnine, corydine and isocorydine, and *D. Cucullaria* contains cryptopine and two other crystalline alkaloids; the tubers of both contain about 25 per cent. of sucrose.

Action and Uses.—Corydalis is reputed to have tonic and diuretic properties and may be used in the form of a decoction.

Dose.—0·3 to 1 gramme (5 to 15 grains).

BULBOCAPNINA.—Bulbocapnine, $C_{19}H_{19}O_4N$, is one of the alkaloids occurring in the tubers of *Ducentra canadensis* and *Corydalis tuberosa*. It may be obtained by mixing the finely ground roots with lime and extracting with benzene. The mixture of alkaloids obtained after removal of the benzene is dissolved in alcohol and made just acid to congo-red with hydrochloric acid. The hydrochloride of bulbocapnine (melting-point, 270°) separates on standing. Bulbocapnine is precipitated from an aqueous solution of the hydrochloride by the addition of ammonia. It crystallises from alcohol in needles (melting-point, 199°). It is insoluble in water, but readily soluble in chloroform. Bulbocapnine is administered in the form of tablets containing 0·1 gramme ($1\frac{1}{2}$ grains), or by the subcutaneous injection of a solution containing the same amount, in the symptomatic treatment of post-encephalitic conditions.

COTARNINÆ CHLORIDUM

(Cotarn. Chlorid.)

Cotarnine Chloride

Synonym—Cotarnine Hydrochloride.

Cotarnine chloride may be prepared by dissolving cotarnine in hydrochloric acid and evaporating the resulting solution, when the salt

crystallises out. It occurs as a pale yellow, crystalline powder, deliquescent in moist air and having a bitter taste. On dissolving 0.1 gramme in 3 millilitres of water and adding 3 drops of 15 per cent. sodium hydroxide solution, a turbidity is produced which disappears on shaking. From this clear solution the free base soon crystallises, especially on stirring with a glass rod. A solution of 0.2 gramme in 10 millilitres of distilled water yields, on the addition of N/10 iodine, a brown precipitate of cotarnine periodide which, when collected and dried over sulphuric acid, melts at 142° to 144°. When heated, cotarnine chloride yields a reddish-brown liquid, evolving characteristic disagreeable fumes, and gradually chars.

Readily **soluble** in water and in alcohol, forming yellow solutions; soluble in warm dehydrated alcohol and precipitated from the solution in a crystalline state by the addition of ether.

Standard.—Cotarnine chloride loses, on drying at 100°, not more than 12.5 per cent. of its weight. Ash, not more than 0.5 per cent. A 5 per cent. w/v solution in water is neutral to litmus.

Action and Uses.—The salts of cotarnine excite the isolated uterus and set up uterine contractions. The calibre of the arterioles is usually unchanged, and the coagulation time of the blood is not affected. The rational application of these compounds appears therefore to be limited to cases of uterine hæmorrhage. Cotarnine chloride is used as a styptic and has been recommended in all forms of uterine hæmorrhage, especially menorrhagia and the bleeding from uterine fibroids. Others regard it as a uterine sedative and use it to lessen the pain of dysmenorrhœa. Clinical reports on its action and value are often contradictory. It is used **externally** in the form of wool (30 per cent.) and gauze, or a 2 per cent. solution is applied on a tampon. The wool may be used to plug the nose in epistaxis, or to stop bleeding after tooth extraction. Bougies to check bleeding from the urethra may contain 0.03 gramme ($\frac{1}{2}$ grain) in each. Cotarnine chloride may be **administered** in powders, tablets, or cachets, or in aqueous solution, orally or hypodermically. Solutions for **injection** may be sterilised by tyndallisation, by filtration, or by heating at 100° for thirty minutes. The containers should comply with the tests for limit of alkalinity of glass, and the solution should be protected from light.

Dose.—0.02 to 0.1 gramme ($\frac{1}{3}$ to 1 $\frac{1}{2}$ grains).

COTARNINA.—Cotarnine, $C_{12}H_{15}O_4N$, is obtained by the oxidation of narcotine with nitric acid. It is a tertiary base, reacting with acids to give salts of the quaternary cotarnine hydroxide. It occurs in colourless needles melting at 132° to 135°, with decomposition. It is precipitated by tannic acid, ferrous salts, copper sulphate and other alkaloidal reagents. It is dissolved by concentrated nitric acid with the production of a red colouration and oxalic acid. The base is allied to hydrastinine and on reduction yields hydrocotarnine, $C_{12}H_{15}O_3N$. It is sparingly soluble in water, more soluble in alcohol and readily soluble in ether.

COTARNINÆ PHTHALAS.—Cotarnine phthalate is the acid phthalate of cotarnine. It occurs as a pale yellow, crystalline powder, melting at 113°. It is soluble in water (about 1 in 60) and contains about 59 per cent. of the base,

cotarnine. Cotarnine phthalate has been recommended for hæmaturia, given internally in similar doses to the chloride and used by irrigation (2 per cent. solution). Solutions for injection may be sterilised by tyndallisation, by filtration, or by heating at 100° for thirty minutes. The containers must comply with the tests for limit of alkalinity of glass, and the solution should be protected from light.

COTO

(Coto)

Coto

Synonym—Paracoto.

Coto is a bark of unknown botanical source derived from a large tree, probably a species of *Nectandra* (Fam. Lauracæ). It is obtained from Bolivia. The formerly so-called true coto bark is no longer an article of commerce.

The bark occurs in flat or slightly curved, heavy pieces up to about 60 centimetres long, 6 centimetres broad, and 8 to 14 millimetres thick. The external surface has occasionally a whitish to brownish cork with longitudinal fissures and transverse cracks, or more usually a thin, smooth, brown cork layer, or exposed, smooth, cinnamon-brown cortex. The inner surface is somewhat coarsely striated with longitudinal ridges due to elongated groups of sclerenchymatous cells. The fracture is short and granular in the outer portion and coarsely fibrous in the inner portion, with projecting points of sclerenchyma. The smoothed, transverse surface of the soaked bark shows a paler brown, narrow zone of sclerenchyma just below the outer surface, and a wide, brown secondary phloem containing paler groups of sclerenchyma scattered through it. The odour is aromatic, camphoraceous and pungent, and the taste hot and biting. The bark originally imported as coto bark has a more nutmeg-like odour and a more peppery taste; under a lens the fractured surfaces glisten with minute crystals.

The diagnostic **microscopical** characters are the masses of stone cells with thick, stratified, pitted walls and narrow lumina, their long axes measuring about 280 microns, and set either tangentially or longitudinally; the oil cells alternating tangentially with collapsed sieve tissue; the cork cells, many of which are strongly thickened, lignified and pitted.

Coto **contains** paracotoin (dioxymethylenephencylcumalin), a crystalline bitter principle, which gives a yellow colour with nitric acid; other constituents are leucotin, hydrocotoin (benzoylphloroglucinol dimethylether), methylhydrocotoin, protocotoin, methylprotocotoin (oxyleucotin) and piperonylic acid. So-called true coto bark contains the substance originally named cotoin (benzoylphloroglucinol methylether), a crystalline powder, which yields a red colour with nitric acid, and leucotin (phenylcumalin). The substance now known as cotoin is paracotoin. Both barks also contain a little volatile oil, resin and tannin.

Action and Uses.—Coto is said to increase the appetite and the absorption of fluid by the intestinal mucosa, possibly by vasodilation. It is used as an astringent in the treatment of diarrhœa. It is **administered** as tincture and liquid extract, and may be prescribed with aromatic powder of chalk or chalk mixture.

Dose.—0·06 to 0·5 gramme (1 to 8 grains).

Preparations

Extractum Coto Liquidum, B.P.C.—(Ext. Coto Liq.)—Liquid Extract of Coto. 1 in 1. Dose.—0·3 to 1 millilitre (5 to 15 minims).

Tinctura Coto, B.P.C.—(Tinct. Coto)—Tincture of Coto. 1 in 10. Dose.—0·6 to 2 millilitres (10 to 30 minims).

COUMARINUM

(Coumar.)

Coumarin

Coumarin, the lactone of coumaric acid, $\text{C}_6\text{H}_4(\text{OH})\cdot\text{CH}:\text{CH}\cdot\text{COOH}$, is the odorous principle of the Tonka or Tonquin bean, *Dipteryx odorata* Willd., and *D. oppositifolia* Willd. (Fam. Leguminosæ). It may be prepared synthetically by heating salicylic aldehyde, acetic anhydride and anhydrous sodium acetate under a reflux condenser, cooling, and adding water to the crystalline mass obtained; the oily liquid which separates is distilled, and the coumarin obtained is dissolved in hot water and crystallised. It occurs in the form of colourless, prismatic crystals having a characteristic, persistent, fragrant odour and a bitter, aromatic taste. It commences to sublime at about 100° and boils at about 290° , without decomposition. On the addition of iodine solution to a saturated aqueous solution a brown, flocculent precipitate is produced which, on shaking, coagulates to a dark green mass, leaving a clear liquid. When fused with caustic potash it is converted into salicylic acid. It should be **stored** in amber-coloured bottles and protected from light.

Soluble in water (1 in 500) and boiling water (1 in 50); readily soluble in alcohol, ether (1 in 7), chloroform, fixed oils, volatile oils, and solutions of the alkali hydroxides.

Standard.—Coumarin melts between 68° and 70° . Ash, not more than 0·05 per cent. When warmed with alcoholic potassium hydroxide solution and a few drops of chloroform, no odour of phenyl isocyanide is produced (absence of acetanilide). 0·1 gramme dissolved in 1 millilitre of sulphuric acid forms a solution not darker than pale yellow (limit of readily carbonisable matter).

Action and Uses.—Coumarin has a powerful anæsthetic action, but readily causes vomiting and is, therefore, unsuitable for use as a

hypnotic. Applied directly to the mucous membrane, coumarin is extremely irritating and, after prolonged use, gives rise to an eczematous eruption. For this reason, care should be taken that the drug is not inhaled, when powdering it. Coumarin is used in perfumery, not only on account of its own fragrance, but for its property of fixing other odours. It is employed in pharmacy to disguise disagreeable odours, especially that of iodoform, for which purpose 1 part of coumarin is used with 50 parts of iodoform.

SODII COUMARAS.—Sodium *o*-coumarate in 22 per cent. solution has been used in treating cancerous growths, in doses of 1·5 millilitres (25 minims), injected into the diseased area.

CREOSOTI CARBONAS

(Creosot. Carb.)

Creosote Carbonate

Creosote carbonate is a mixture of the carbonic esters of the various constituents of creosote, namely creosol, guaiacol and cresol. It may be prepared by conducting a stream of carbonyl chloride (phosgene gas), into a solution of creosote in sodium hydroxide solution, washing the oily liquid which separates with weak alkali solution and then with water. It contains the equivalent of about 90 per cent. of creosote. It occurs in the form of a clear, colourless or amber-coloured, viscid liquid of about the consistence of syrup at ordinary temperatures, but more fluid when hot. It is neutral and has a very slight odour and a sweetish, oleaginous taste, suggesting, after a time, that of creosote. On standing in the cold, crystals of guaiacol carbonate separate, but these are redissolved on warming. On heating with 20 parts of alcoholic potassium hydroxide solution and cooling, a crystalline precipitate of potassium carbonate is formed.

Soluble in alcohol, ether, chloroform, benzene, amyl alcohol and volatile and fixed oils; insoluble in water and glycerin.

Standard.—Creosote carbonate has a specific gravity of 1·150 to 1·180. Ash, not more than 0·1 per cent. A solution in alcohol (1 in 5) is neutral to litmus paper, and no green colour develops on the addition of 1 drop of ferric chloride solution (limit of free creosote). Not darker than a light brown colouration is produced when mixed with about 10 times its volume of sulphuric acid (limit of readily carbonisable impurities).

Action and Uses.—Creosote carbonate passes through the stomach unchanged, but is decomposed with liberation of creosote by the alkaline intestinal secretions. It is, therefore, not an efficient substitute for creosote when it is desired to produce its effects in the stomach. It is employed chiefly in pulmonary tuberculosis, chronic bronchitis and pneumonia, and as an intestinal antiseptic. It may be conveniently

administered in warm milk or in capsules. Large doses, 4 millilitres (1 fluid drachm) or more, are sometimes given.

Dose.—0·3 to 1·2 millilitres (5 to 20 minims).

CREOSOTUM

(Creosot.)

Creosote

Synonym—Creasote.

Creosote is a mixture of guaiacol, creosol and other phenols obtained by the fractional distillation of wood tar. It occurs as a colourless or pale yellow, highly refractive liquid with a strong, characteristic odour and a burning taste. On the addition of 1 drop of ferric chloride solution to 10 millilitres of a saturated aqueous solution of creosote, a transient violet-blue colour is produced. On the further addition of a few drops of ferric chloride solution, the liquid becomes cloudy, the colour changes through greyish-green to brown and a brown precipitate is produced. Creosote may be distinguished from coal-tar phenols by its neutral or faintly acid reaction to litmus and by the absence of a permanent coagulum when shaken with an equal volume of flexible collodion prepared with pyroxylin having the minimum viscosity specified in the British Pharmacopœia. It should be **stored** in well-closed bottles and protected from light.

Soluble in water (about 1 in 150); miscible with alcohol, ether, chloroform, glycerin, glacial acetic acid, fixed and volatile oils.

Standard, B.P.—Creosote has a specific gravity of not less than 1·070. It begins to distil at about 200° and not less than 95 per cent. v/v distils between 200° and 230°. It complies also with a limit test for hydrocarbons and bases.

Action and Uses.—Creosote is a powerful antiseptic, deodorant and antiputrescent; its action resembles that of phenol, but it is less irritating and poisonous. As an inhalation it is useful in phthisis, pulmonary gangrene and fœtid bronchitis. When taken by the mouth it promotes expectoration. In pulmonary tuberculosis with a secondary infection, creosote is undoubtedly useful, acting as a deodorant to the foul expectoration and perhaps converting the mixed infection into a simple tuberculous condition. It is therefore largely employed in pulmonary tuberculosis, although clinical opinion is divided as to its value. Guaiacol and guaiacol carbonate have now to some extent replaced creosote for this purpose. Creosote is carminative and, being a gastro-intestinal antiseptic, is useful in flatulent dyspepsia. **Externally**, it is used in parasitic skin diseases in the form of Unguentum Creosoti.

Creosote may be **administered** in solution in water, flavoured with spirit of juniper and liquid extract of liquorice, or as Syrupus Creosoti Compositus. Owing to its disagreeable taste, creosote may be given in

capsules; it should first be mixed with one and a half to two volumes of oil. Capsules are also made containing creosote in combination with cod-liver oil, or *Emulsio Olei Morrhue et Creosoti* may be given. Pills may be prepared with soap and liquorice as excipients. In phthisis and fœtid bronchitis, it may be inhaled from hot water (using 12 minims to 8 fluid ounces). A mixture of creosote with phenol and spirit of chloroform in equal parts, inhaled continuously during the day from an oro-nasal inhaler, has given good results in phthisis. Creosote is employed medicinally as an inhalation in whooping cough and other respiratory disorders, being vaporised in a suitable apparatus until the atmosphere of the sick-room is sufficiently saturated. When applied to carious teeth it is deodorant and antiseptic; it is also a local anæsthetic, allaying toothache.

Dose.—0·12 to 0·6 millilitre (2 to 10 minims).

Preparations

Emulsio Olei Morrhue et Creosoti, B.P.C.—(*Emuls. Ol. Morrh. et Creosot.*)—Emulsion of Cod-liver Oil and Creosote. This emulsion contains 33·3 per cent. v/v of cod-liver oil, with 4 minims of creosote in each fluid ounce. Dose.—8 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

Syrupus Creosoti Compositus, B.P.C.—(*Syr. Creosot. Co.*)—Compound Syrup of Creosote. Each fluid drachm contains 1 minim of creosote with spirit of chloroform, glycerin, syrup of pine and syrup. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Unguentum Creosoti, B.P.C.—(*Ung. Creosot.*)—Creosote Ointment. Creosote, 10 per cent., in white beeswax, lard, and hard and soft paraffins.

This ointment, prepared with a basis of hard paraffin, 40 per cent., and white soft paraffin, 50 per cent., was included in the British Pharmacopœia, 1914.

CRESOL

(Cresol)

Cresol

Synonyms—Acidum Cresylicum; Cresylic Acid.

Cresol is a mixture of *o*-, *m*-, and *p*-cresols, $\text{CH}_3\cdot\text{C}_6\text{H}_4\cdot\text{OH}$, with xylenols and other homologues obtained from coal tar. It occurs as an almost colourless or pale brownish-yellow liquid, which darkens on keeping or on exposure to light and has a characteristic phenolic odour. A dilute aqueous solution gives a transient bluish colour on the addition of ferric chloride solution, and a pale yellow, flocculent precipitate on the addition of bromine water. *o*-Cresol is a colourless, deliquescent solid with a characteristic odour; it becomes yellow on keeping, melts at about 30° and boils at about 191°. *m*-Cresol is a colourless or yellowish liquid, slightly soluble in water, readily soluble in organic solvents; it has a melting-point of about 10° and a boiling-point of about 202°. *p*-Cresol is a crystalline solid, slightly soluble in water, readily soluble in

alcohol and ether; it has a melting-point of about 36° and a boiling-point of about 201° . Commercial cresylic acid, or "crude carbolic acid," has a specific gravity of about 1.04 and contains varying proportions of cresols with small proportions of phenol and higher phenols. Cresol should be **stored** in well-closed containers, away from light.

Almost completely **soluble** in water (1 in 50); miscible with alcohol (90 per cent.), ether, chloroform, glycerin, and fixed and volatile oils.

Standard, B.P.—Cresol forms a neutral aqueous solution and has a specific gravity of 1.035 to 1.050. Not more than 2 per cent. v/v distills below 188° and not less than 80 per cent. v/v between 195° and 205° . Residue on evaporation on a water-bath, not more than 0.1 per cent. w/v. It complies also with limit tests for hydrocarbons, volatile bases and sulphur compounds.

Action and Uses.—The effects produced by cresol are similar to those produced by phenol. It is useful as an inhalation in whooping cough, the atmosphere of the sick-room being impregnated with its vapour by means of a suitable apparatus. It has been **administered** as an antiseptic to the gastro-intestinal tract, usually diluted with olive oil and enclosed in gelatin or glutoid capsules. For **external** use, it may advantageously replace phenol in many preparations, such as lotions and ointments, since it is less caustic and less poisonous to mammals.

Cresol is employed largely as a disinfectant in the form of Liquor Cresolis Saponatus (lysol), which forms clear solutions with water. Crude cresol and higher fractions of coal tar distillates are also used in the manufacture of different types of disinfectants and in the preparation of liquids for agricultural and horticultural purposes such as sheep-dips and weed-killers. The "carbolic" powders of commerce contain crude cresol mixed with a siliceous base, but the disinfectant properties of such powders are almost negligible. In cases of **poisoning** by cresol or the higher homologues of phenol, the procedure described under Phenol should be followed.

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

METHYLCYCLOHEXANOLUM.—Methylcyclohexanol, or hexahydrocresol, is a mixture of three isomeric secondary alcohols of the formula $C_7H_{14}O$, each of which can exist in stereoisomeric modifications. It is prepared by the hydrogenation of cresol and occurs as a somewhat toxic, oily liquid having a persistent, camphoraceous odour. It has a specific gravity of about 0.925 to 0.930, and a boiling-range of 160° to 180° . It is slightly soluble in water, and is used as a solvent in the manufacture of lacquers and varnishes.

METHYLCYCLOHEXANONUM.—Methylcyclohexanone, $C_7H_{12}O$, may be obtained from the cresols by catalytic hydrogenation and consists of a mixture of the three isomers. It occurs as a colourless oil with a peppermint-like odour and has a specific gravity of 0.925 to 0.930 and a boiling-range of 160° to 170° . It is used as a solvent in the manufacture of lacquers and varnishes.

METHYLCYCLOHEXANYLIS ACETAS.—Methylcyclohexanyl acetate, $C_{13}H_{24}O_2$, is a mixture of the esters obtained by acetylating methylcyclohexanol. It has a specific gravity of about 0.94 to 0.98, and is used as a solvent.

METHYLCYCLOHEXANYLIS OXALAS.—Methylcyclohexanyl oxalate, $(\text{COOC}_6\text{H}_{11})_2$, occurs as a viscous, colourless, odourless liquid with a specific gravity of about 1·035 and is used as a plasticiser.

TRICRESYLIS PHOSPHAS.—Tricresyl phosphate, $(\text{CH}_3\cdot\text{C}_6\text{H}_4\text{O})_3\text{PO}_4$, occurs in commerce as the tri-ortho compound which is a crystalline solid when pure, melting at 18° , but usually occurs as a liquid owing to the presence of small quantities of other isomerides. It has a specific gravity of about 1·177 to 1·180 and a boiling-range of 430° to 440° . It is extensively used as a plasticiser in the manufacture of lacquers and varnishes.

Preparations

Liquor Cresolis Saponatus, B.P.—(Liq. Cresol. Sap.)—Solution of Cresol with Soap. *Syn.*—(For general use in Great Britain and Northern Ireland only) Lysol. It contains 50 per cent. v/v of cresol in a saponaceous solvent (limits, 47 to 53) and is miscible with water in all proportions. It may be prepared by dissolving cresol in linseed oil saponified with potassium hydroxide. The 5 per cent. v/v aqueous solution shows no opalescence on standing for not less than three hours. It complies also with limit tests for alkali and sulphur compounds, and the separated cresol complies with limit tests for hydrocarbons and volatile bases.

A similar preparation was included in the British Pharmaceutical Codex, 1923, under the name of Liquor Cresolis Glycerinatus.

Vapor Cresolis Compositus, B.P.C.—(Vap. Cresol. Co.)—Compound Cresol Inhalation. Creosote, 1 per cent. v/v, and oils of eucalyptus and Siberian fir, of each 2 per cent. v/v, in cresol.

CRETA

(Cret.)

Chalk

Synonym—Creta Præparata; Prepared Chalk.

Chalk is native calcium carbonate freed from most of its impurities by elutriation. It occurs in white or greyish-white, friable masses or powder, without odour or taste. When examined microscopically it is seen to consist of the entire and broken tests of cretaceous foraminifera such as *Globigerina* (about 35 by 30 to 140 by 115 microns) and *Textularia* (about 50 by 40 to 175 by 110 microns), and minute rounded, ovoid or flattened bodies named morpholites (about 10 to 15 microns in diameter).

Insoluble in water and alcohol (90 per cent.).

Standard, B.P.—Chalk contains not less than 97 per cent. of CaCO_3 , calculated on the substance dried at 100° . Loss on drying at 100° , not more than 1 per cent. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. When boiled with water, the filtrate is neutral to litmus. It complies also with limit tests for aluminium, iron, phosphate and matter insoluble in hydrochloric acid, chloride and sulphate.

Action and Uses.—Chalk is astringent and antacid. For diarrhœa it is administered as Mistura Cretæ or Mistura Cretæ Composita,

or with aromatics in the form of *Pulvis Cretæ Aromaticus*, with or without opium. A mixture formerly known as Board of Health cholera mixture closely resembled *Mistura Cretæ Composita* and was used in the same manner. As an antacid, chalk is largely employed with bismuth carbonate, magnesium carbonate and sodium bicarbonate in the treatment of gastric and duodenal ulcer. **Externally**, it is protective and mildly astringent, occasionally being used as a dusting powder with zinc oxide or calamine, or as *Unguentum Cretæ*, for eczema and burns.

Dose.— 1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

Preparations

Mistura Cretæ, B.P.C.—(*Mist. Cret.*)—Chalk Mixture. Each fluid ounce contains about 13 grains of chalk, with sucrose, *tragacanth* and cinnamon water. Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

This mixture was included in the British Pharmacopœia, 1914.

Mistura Cretæ Composita, B.P.C.—(*Mist. Cret. Co.*)—Compound Chalk Mixture. Each fluid ounce contains 9 grains of aromatic powder of chalk, 9 grains of chalk, 30 minims of tincture of catechu and 3 minims of tincture of opium, with sucrose, aromatic spirit of ammonia, compound tincture of cardamom, *tragacanth* and cinnamon water. Dose.— 30 millilitres (1 fluid ounce) for an adult; 15 millilitres ($\frac{1}{2}$ fluid ounce) for a child twelve years old; 8 millilitres (2 fluid drachms) for a child seven years old.

Pulvis Cretæ Aromaticus, B.P.—(*Pulv. Cret. Aromat.*)—Aromatic Powder of Chalk. Chalk, 25 per cent., with cinnamon, nutmeg, clove, cardamom and sucrose. Dose.— 0·6 to 4 grammes (10 to 60 grains).

Pulvis Cretæ Aromaticus cum Opio, B.P.—(*Pulv. Cret. Aromat. c. Opio*)—Aromatic Powder of Chalk with Opium. Powdered opium, 2·5 per cent., with aromatic powder of chalk. It contains 0·25 per cent. of anhydrous morphine (limits, 0·235 to 0·265); 4 grammes contains 0·01 gramme, and 60 grains about $\frac{1}{4}$ grain, of anhydrous morphine. Dose.— 0·6 to 4 grammes (10 to 60 grains).

Unguentum Cretæ, B.P.C.—(*Ung. Cret.*)—Chalk Ointment. Chalk, 20 per cent., in *spermaceti* ointment.

CROCUS

(Croc.)

Saffron

Saffron consists of the dried stigmas and tops of the styles of *Crocus sativus* Linn. (Fam. Iridaceæ), a plant cultivated in Spain, and to a less extent in France and Italy. It should be **stored** in well-closed containers and protected from light.

The drug occurs in red or reddish-brown, tangled masses, composed of single stigmas or one to three stigmas attached to a portion of the yellow style. The stigmas are hollow, narrowly obconical and partially split longitudinally on the inner side; they are about 25 millimetres long and 4 millimetres wide at the upper end, which is irregularly notched; the free margin bears cylindrical, stigmatic papillæ up to 150 microns long. When quite dry, saffron is brittle to the touch; when damp, it is more or less flexible. Saffron has a strong aromatic odour, which is

intensified when the drug is damped and warmed; the taste is slightly bitter, and is characteristic. When saffron is placed in concentrated sulphuric acid a deep blue colour develops. When calculated on the dried drug, the water-soluble extractive is about 58 per cent., which is invariably lower than the alcohol extractive (alcohol, 60 per cent.) on the same sample; the total reducing sugar, after inversion, calculated as dextrose, is about 25 per cent. and the total nitrogen about 2.3 per cent.

Saffron **contains** about 1 per cent. of volatile oil, a colourless, bitter glycoside, picrocrocin, and crocin or polychroite, the glycoside of the colouring matter, crocetin. The latter appears to be a mixture of three substances, α -, β - and γ -crocetins. Crocin is an amorphous red powder and, like carotene, dissolves in concentrated sulphuric acid, forming a deep blue solution which on standing changes to violet, red and finally brown; it is coloured green by nitric acid.

Standard.—Saffron contains not more than 8 per cent. of styles and anthers, and not more than 2 per cent. of foreign organic matter. Alcohol extractive (alcohol, 60 per cent.), calculated on the dried drug, not less than 60 per cent. Ash, not more than 7.5 per cent. Light petroleum extractive, not more than 1 per cent. Moisture, not more than 12.5 per cent. 0.02 gramme of saffron yields to 100 millilitres of water a yellow colour similar in tint to, and not less in intensity than, that of 0.1 per cent. w/v potassium dichromate solution. The taste is devoid of any trace of sweetness.

Uses.—Saffron is used almost entirely for its colouring and flavouring properties. Syrupus Croci, which has a brilliant colour when fresh, but deposits on keeping, and Glycerinum Croci are used as colouring agents. A tincture [Tinctura Croci, 1 in 5 in alcohol (60 per cent.)] is also used as a colouring agent. Saffron preparations as colouring agents are now largely replaced by dyes such as tartrazine and orange G; Liquor Tartrazinæ Compositus is suitable for general pharmaceutical use.

MAIDIS STIGMATA.—Maize stigmas, or corn silk, consists of the fresh or dried stigmas and styles obtained from *Zea Mays* Linn. (Fam. Graminaceæ), an annual plant indigenous to tropical America, but widely cultivated in tropical and temperate regions. It occurs as a loose, tangled mass of slender, yellowish or brownish, filamentous styles from 5 to 20 centimetres long, having slender, bifid stigmas 0.5 to 3 millimetres long. The chief constituents are resin and maizenic acid. Maize stigmas are rarely used in medicine, but a liquid extract (Extractum Maidis Liquidum, 1 in 1; dose, 1 to 2 fluid drachms), and a syrup [Syrupus Maidis, 1 (liquid extract) in 10; dose, $\frac{1}{2}$ to $\frac{1}{2}$ fluid ounce] were formerly employed and were considered to possess demulcent and diuretic properties.

Preparations

Glycerinum Croci, B.P.C.—(Glycer. Croc.)—Glycerin of Saffron. Saffron, 1 in 40, in glycerin and alcohol (60 per cent.).

Syrupus Croci, B.P.C.—(Syr. Croc.)—Syrup of Saffron. Glycerin of saffron, 1 in 8, in syrup. Dose.—As a colouring and flavouring agent, 4 millilitres (1 fluid drachm) to 30 millilitres (1 fluid ounce) of mixture.

CUBEBA

(Cubeb.)

Cubeb*Synonyms*—Cubebæ Fructus; Tailed Pepper.

Cubeb consists of the dried, fully-grown, unripe fruits of *Piper Cubeba* Linn. (Fam. Piperacæ), a plant indigenous to the Malay Archipelago. It is collected when green, stripped from the rachis and dried in the sun.

The dried fruits are blackish in colour, with a greyish bloom, nearly globular in shape, sometimes depressed at the base and about 4 millimetres in diameter. The pericarp is reticulately wrinkled; at the apex it bears a tri-radiate stigma and at the base it is abnormally prolonged into a slender, firmly attached stalk about 4 millimetres in length; it contains a single seed. The odour is strong, spicy and characteristic; the taste is strong, spicy and somewhat bitter. When the powdered fruit is sprinkled on the surface of 80 per cent. sulphuric acid, each particle becomes surrounded by a crimson zone.

The diagnostic **microscopical** characters are the single (only here and there double) row of radially elongated, rectangular, sclerenchymatous cells in the inner layer of the pericarp; the brown cells of the outer epidermis containing small prisms of calcium oxalate; the hypodermis consisting of small groups of rectangular stone cells separated by thin-walled parenchyma; the parenchyma of the mesocarp containing rounded starch grains and prisms of calcium oxalate; the large oil cells from the mesocarp and also from the perisperm of the seed (these are often broken in the powder); the large, polygonal, thin-walled cells of the perisperm filled with polyhedral starch grains; the reddish-brown cells of the seed coat crossed by the cells of the hyaline layer; the absence of beaker-cells.

Cubeb **contains** from 10 to 18 per cent. of volatile oil. It also contains resins, cubebic acid (0.96 per cent.) which is amorphous and gives a cherry-red colour with sulphuric acid, and cubebin which is colourless and crystalline and gives a crimson colour with sulphuric acid.

Substitutes.—Cubeb is liable to admixture with a number of fruits more or less similar in appearance. They can be distinguished by their different structure and by their not giving a crimson colour with sulphuric acid. Amongst the commoner admixtures are the following:—"Rinca Badak," a false cubeb, greyish in tint and larger in size (about 6 millimetres in diameter) than true cubeb; it has a mace-like odour; the epicarpic stone cells are larger than those of genuine cubeb. When cubeb containing an admixture of these fruits is used, it is liable to cause symptoms of poisoning. The fruits of *Piper crassipes* Korthals are 4 to 7 millimetres in diameter, the pedicels 7 to 11 millimetres long, and the base of the fruit is depressed; they have a very bitter taste and an odour different from cubeb. *Piper ribesoides* Wallich., the fruits of which are 4 to 6 millimetres in diameter, the pedicels about 6 millimetres long, the colour yellowish or brownish-grey and the taste less pungent than true cubeb. *Piper mollissimum* Blume (Kebæ Cubeb), the fruits of which are 4 to 7 millimetres in diameter, the pedicels about 16 millimetres long, coarsely wrinkled and grey in tint. *Piper venosum* C. DC. and *Piper muricatum* Blume both have

fruits larger than true cubeb but the pedicels are short or absent. The fruits of *Piper Lowong* Blume resemble true cubeb in appearance but, as in those of *P. molli-simum*, stone cells are absent from the endocarp.

Standard.—Cubeb contains not more than 7 per cent. of shrivelled, immature fruits, rachis and stems, and not more than 2 per cent. of other foreign organic matter. Ash, not more than 8 per cent.

Cubeb, in powder (*Pulvis Cubebæ* : *Pulv. Cubeb.*), contains the constituents and possesses the diagnostic microscopical characters of *Cubeba*, and complies with the limit for ash of the unground drug.

Action and Uses.—Cubeb has an action similar to but weaker than that of copaiba. It is used internally as an antiseptic and diuretic in gonorrhœa and in the form of lozenges as a stimulating and antiseptic expectorant to the bronchial mucous membrane.

Dose.—2 to 4 grammes ($\frac{1}{2}$ to 1 drachm).

Preparations

Extractum Cubebæ Liquidum, B.P.C.—(*Ext. Cubeb. Liq.*)—Liquid Extract of Cubeb. 1 in 1. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Oleoresina Cubebæ, B.P.C.—(*Oleotes. Cubeb.*)—Oleoresin of Cubeb. The ether-soluble matter of cubeb. Dose.—0.3 to 2 millilitres (5 to 30 minims).

Tinctura Cubebæ, B.P.C.—(*Tinct. Cubeb.*)—Tincture of Cubeb. 1 in 5. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopœia, 1914.

CUCURBITA

(*Cucurb.*)

Melon Pumpkin Seed

Synonym—*Cucurbitæ Semina Præparata.*

Melon pumpkin seed consists of the fresh seeds of *Cucurbita maxima* Duchesne (Fam. *Cucurbitaceæ*), a native of the Levant and cultivated on the shores of the Mediterranean.

The seeds are ovate in shape and flat, measuring from 8 to 12 millimetres in length, 9 to 12 millimetres in breadth and about 4 millimetres in thickness; they have a flat ridge and shallow groove round the edge; the testa is light brown to white in colour, brittle and finely pitted. The embryo consists of two white, oily, easily separable cotyledons, with a short radicle. When fresh, the seed has a faint odour and a slight taste. For medicinal purposes the testa and tegmen are removed, and the seed should not be used if more than a month old.

Melon pumpkin seed **contains** about 30 per cent. of a reddish fixed oil, protein, sugar, starch and an acrid resin.

Action and Uses.—Melon pumpkin seed has been employed as a tænicide. Its use should be preceded by the administration of a saline purge. The patient fasts and takes about 100 grammes (3 ounces)

of bruised seed, mixed with a little water or milk to a creamy consistence, as a single dose. After an interval of a few hours a purgative dose of castor oil is given. Experiment has failed to indicate that either the oil or resin has any definite action as a vermifuge; no substance of physiological activity has been isolated either from the kernels or shells of the seed.

CUMINUM

(Cumīn.)

Cummin

Cummin is the fruit of *Cuminum Cyminum* Linn. (Fam. Umbelliferae), a small plant indigenous to the Upper Nile territory, and cultivated in Northern Africa, Sicily, Malta and India. The plants are cut and threshed when the fruit is ripe.

The fruit is a cremocarp, brown in colour with lighter-coloured ridges. It is of an elongated oval shape, about 4 to 6 millimetres long, tapering onwards both base and apex. The mericarps are generally separate. Each mericarp has five longitudinal, hairy primary ridges running from base to apex; alternating with these are secondary ridges which are flatter and bear conspicuous emergences. The odour and taste are characteristic, slightly resembling those of anise, but much less agreeable. Microscopically, the transverse section of the mericarp exhibits an oily endosperm and six vittæ, four being on the dorsal surface and two on the commissural surface; the large pluriserial hairs are characteristic.

Cummin **contains** from 2 to 4 per cent. of a volatile oil which contains 25 to 40 per cent. of cuminic aldehyde (cuminal). It yields about 8 per cent. of ash.

Standard.—Cummin contains not more than 2 per cent. of foreign organic matter.

Action and Uses.—Cummin is used as a carminative, chiefly in spices and veterinary medicine.

CUPRI NITRAS

(Cupr. Nit.)

Copper Nitrate

Synonym—Cupric Nitrate.

Copper nitrate may be prepared by dissolving copper or copper oxide in nitric acid and crystallising at a temperature not below 26°. Crystallised below 21°, the hexahydrate is formed, which is deeper in colour and dissolves in its water of crystallisation at about 25°. It occurs in the

form of a deliquescent, blue, crystalline powder, or sometimes in large blue crystals. Melting-point, about 115° . It decomposes on heating, becoming basic. The salt has strong oxidising properties. It readily unites with ammonia, amino-acids, aniline, etc., forming complex salts. It should be **stored** in well-stoppered bottles.

Very **soluble** in water and alcohol.

Action and Uses.—Copper nitrate is a powerful oxidising agent. It may be used as a substitute for the sulphate in astringent lotions.

CUPRI CITRAS.—Copper citrate is used in the form of a 5 per cent. ointment in the treatment of ophthalmic ulcerations and trachoma.

CUPRI OLEAS

(Cupr. Oleas.)

Copper Oleate

Copper oleate is prepared by dissolving 1 part of copper sulphate and 2.5 parts of hard soap separately, each in 50 parts of distilled water, mixing the two solutions and heating till the precipitate melts and agglomerates; the product is then washed with boiling water, collected and dried. It occurs in dark green or greenish-blue masses or powder, and contains the equivalent of about 12 per cent. of CuO .

Insoluble in water; soluble in ether.

Action and Uses.—Copper oleate is used as Unguentum Cupri Oleatis, an astringent, antiseptic and parasiticide ointment recommended especially for ringworm.

Preparation

Unguentum Cupri Oleatis, B.P.C.—(Ung. Cupr. Oleat.)—Copper Oleate Ointment. Copper oleate, 12.5 per cent., in yellow soft paraffin.

CUPRI SUBACETAS

(Cupr. Subacet.)

Basic Copper Acetate

Synonyms—Copper Oxyacetate; Verdigris.

Basic copper acetate may be prepared by arranging in alternate layers copper sheets and grape residue undergoing acetous fermentation, or flannel saturated with hot acetic acid. The crust of the acetate is detached from the plates and sold in cakes, either dry or containing 30 to 40 per cent. of water. The composition of the salt varies, but approaches $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot \text{Cu}(\text{OH})_2 \cdot 5\text{H}_2\text{O}$. It forms blue needles or scales which effloresce in air and become green owing to loss of water,

and occurs in commerce as a greenish-blue powder, or in heavy, hard masses of a greenish-blue colour, containing considerable quantities of small crystals, and having an earthy, somewhat crystalline fracture and a slight acetous odour. It is decomposed by heat with the evolution of acetic acid and water. When it is treated with the requisite proportion of arsenic trioxide solution, Schweinfurth's green $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 3\text{CuAs}_2\text{O}_4$, is formed. Dissolved in acetic acid, it is converted into the normal acetate, $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot \text{H}_2\text{O}$, which is known as "distilled" or "crystallised" verdigris.

Partially **soluble** in water, with decomposition; insoluble in alcohol; completely soluble in excess of ammonium carbonate solution.

Action and Uses.—Basic copper acetate has been employed as an escharotic, but is used chiefly in veterinary medicine. *Linimentum Æruginis* (liniment of verdigris) was prepared by dissolving verdigris in vinegar, adding honey and boiling down to a proper consistence; it has been used as an application to indolent ulcers, but is now rarely employed.

CUPRI SULPHAS

(Cupr. Sulph.)

Copper Sulphate

Copper sulphate is cupric sulphate, and may be prepared from copper pyrites, or by the action of sulphuric acid on copper or copper oxide. It occurs in blue, triclinic prisms or as a blue, crystalline powder, and is slowly efflorescent in dry air. The names blue vitriol, blue copperas, and blue stone are sometimes used for crude copper sulphate. The exsiccated salt is nearly colourless, and is sometimes used to detect the presence of water in alcohol and other liquids.

Soluble in water (about 1 in 3) and glycerin (about 1 in 3), almost insoluble in alcohol (90 per cent).

Standard, B.P.—Copper sulphate contains not less than 98.5 per cent. and not more than the equivalent of 101 per cent. of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$. Arsenic limit, 10 parts per million. It complies also with limit tests for acidity, zinc, lead and iron.

Action and Uses.—The soluble salts of copper precipitate proteins from solution and are therefore astringent—or, in strong solutions, corrosive—when applied to the mucous surfaces. Large doses irritate the stomach and intestines and give rise to violent vomiting and purging. Copper sulphate is given **internally** as an emetic; for this purpose a 1 per cent. solution is suitable. Its action is prompt, very little of the salt being absorbed. It is of great value in phosphorus poisoning, where it not only acts as an emetic, but, by forming an insoluble copper phosphide, prevents absorption. It is also used

internally as an astringent, in small doses administered in pill form. Small doses are administered in conjunction with iron in cases of secondary anæmia. **Externally**, copper sulphate is used in solid form as a caustic application to warts and ulcers. Sticks of the salt are prepared for this purpose and are mounted in boxwood holders for gynecological use. Copper sulphate is a useful astringent and antiseptic for application to discharging gums in pyorrhœa alveolaris. Dilute solutions of copper sulphate are used for their effect upon mucous membranes in checking excessive discharges. For ophthalmic use, 0.25 to 0.5 per cent. w/v solutions are suitable; for urethral injections, 0.5 to 1 per cent. w/v solutions. A 2 per cent. w/v solution is employed by ionisation for ringworm, alopecia, etc.

Copper sulphate is used in the preparation of Benedict's, Fehling's, and Pavy's solutions for the detection and determination of dextrose in urine and other fluids, and for the determination of carbohydrates in general analytical work. The salt is a powerful fungicide, and its use in minute quantity has been suggested to prevent the growth of algæ in reservoirs. It is also largely used as a seed dressing and for preventing the growth of certain weeds. Copper sulphate is **incompatible** with alkalis, iodides and vegetable astringents. The best emergency antidote for **poisoning** by salts of copper is white of egg with milk, morphine being given to allay pain.

Dose.—0.016 to 0.12 gramme ($\frac{1}{4}$ to 2 grains); as an emetic, 0.3 to 0.6 gramme (5 to 10 grains).

CURARA

(Curar.)

Curare

Synonyms—Woorara; Woorali; Ourari; Urari.

Curare consists of an extract prepared from the bark of *Strychnos toxifera* Schomb. and other species of *Strychnos* (Fam. Loganiaceæ), liana-like plants growing in British Guiana, French Guiana, Venezuela, Northern Brazil, and Colombia. It is probably prepared by the evaporation of an aqueous decoction or infusion.

Curare varies considerably in appearance and composition. It may occur as a brittle, blackish extract, often containing small cavities. When imported in bamboo, it is dark brown and granular, and frequently exhibits small crystals. When a small fragment is mixed with alcohol and viewed under the microscope, the brownish fluid shows crystals in the form of four-sided prisms (possibly curarine) and minute crystals of calcium oxalate. Curare is without odour, but has a very bitter taste.

The constituents of the drug vary in the different specimens. Gourd curare **contains** the poisonous alkaloid, curarine, $C_{19}H_{26}ON_2$, which

has been obtained as a yellowish-brown powder having a bitter taste; curine, which is less poisonous than curarine, has also been obtained from gourd curare; it is identical with beberine, $C_{36}H_{38}O_6N_2$, the alkaloid from nectandra bark. Bamboo (tube) curare from the Amazon contains the alkaloids, tubocurarine, $C_{19}H_{21}O_4N$, and curine, and pot curare contains the alkaloids, protocurarine, protocurine and protocuridine. Bamboo curare yields about 84 to 88 per cent. to water, gourd curare, 34 to 75 per cent. and pot curare, 50 to 87 per cent.

Action and Uses.—The principal effect of curare is to paralyse the motor nerve-endings in striped muscle; voluntary movements are arrested and death occurs from respiratory failure. Curare acts promptly when introduced subcutaneously, but is almost inert when taken by the mouth, probably owing to its rapid excretion and to the destructive action of the gastric juice. It has sometimes been **administered** in doses of $\frac{1}{30}$ to $\frac{1}{2}$ grain by hypodermic injection in the treatment of tetanus, hydrophobia, and strychnine poisoning. It is used as an arrow-poison by the natives of South America.

CURCUMA

(Curcum.)

Turmeric

Synonyms—Turmeric Rhizome; Turmeric Root.

Turmeric is the dried rhizome of *Curcuma domestica* Val. (Fam. Zingiberaceæ), a native of Southern Asia and largely cultivated in India, China, Java and other tropical countries. The rhizomes are dug up after the herbaceous aerial stems have died down and are then steamed or boiled. They are finally dried and sorted into "bulbs," the stem-producing rhizomes, and "fingers," the lateral, secondary rhizomes. The tinctorial value of the "finger" variety is higher than that of the "bulb."

"Finger" turmeric occurs in nearly straight, sub-cylindrical, hard, heavy, compact pieces, 4 to 7 centimetres long and 1 to 1.5 centimetres wide at the broadest part, bluntly tapering at each end. The outer surface of the rhizome is of a deep yellowish-brown colour, longitudinally wrinkled, and bears transverse rings of leaf-scars. Some pieces have short, lateral branches, or show the scars where these have been broken off. The fracture is short, the broken surface being brownish-yellow, waxy and horny. The transversely cut surface exhibits a paler coloured endodermis; the stele shows numerous, scattered vascular bundles. "Bulb" turmeric resembles "finger" turmeric, but is shorter and thicker. When a piece of filter paper impregnated with an alcoholic extract of turmeric is dried and then moistened with a solution of boric acid slightly acidified with hydrochloric acid and again dried, the filter paper assumes a pink or brownish-red colour which becomes

deep blue or greenish-black on the addition of alkali. The odour and taste are aromatic and characteristic, and, when chewed, turmeric colours the saliva yellow.

The diagnostic **microscopical** characters are the abundant, large, yellow-tinted parenchymatous cells in which are irregular, yellow masses of gelatinised starch, some grains still exhibiting the characteristic scitamineous type and varying in length from 30 to 60 microns; the epidermis, bearing occasional, thick-walled, unicellular trichomes, and beneath it a layer of cork composed of thin-walled cells; the oil cells and cells containing orange-coloured lumps of resin; the vascular bundles, which are not accompanied by a sheath of sclerenchymatous fibres.

Turmeric **contains** curcumin, a yellow, crystalline body, and about 5 per cent. of a volatile oil. The rhizome also contains starch and resin, some of the starch being gelatinised owing to the method by which the drug is prepared. Curcumin dissolves in alcohol to form a deep yellow solution, alkalis changing the colour to reddish-brown. It yields to alcohol (90 per cent.) about 8 per cent. of extractive.

Standard.—Turmeric yields not more than 9 per cent. of ash.

Turmeric, in powder (*Pulvis Curcumæ*: *Pulv. Curcum.*), contains the constituents and possesses the diagnostic microscopical characters of *Curcuma*, and complies with the standard for the unground drug.

Action and Uses.—Turmeric is an aromatic, used principally as a constituent of curry powders and other condiments. Tincture of turmeric (*Tinctura Curcumæ*, 1 in 6) is used as a colouring agent, but the colour is fugitive in solution. Turmeric paper is prepared by steeping unglazed white paper in the tincture, and drying it.

ZEDOARY is the rhizome of *Curcuma Zedoaria* Roscoe (Fam. Zingiberacæ). It is cultivated in India, the rhizome usually being cut into transverse slices and dried. The slices are greyish or yellowish and resemble turmeric in general structure, but contain no curcumin; the starch grains are characteristic. The odour and taste resemble those of ginger, but are less powerful. Zedoary contains resin, about 1 per cent. of volatile oil, and starch.

CUSPARIA

(*Cuspar.*)

Cusparia

Synonyms—Angostura Bark; Cusparia Bark.

Cusparia is the bark obtained from *Galipea officinalis* Hancock (Fam. Rutacæ), a tree growing abundantly on the mountains of Colombia and Venezuela.

The bark occurs in quills or in thin, curved or channelled pieces, often about 10 to 12 or up to 30 centimetres long, 2.5 centimetres wide and 2 millimetres thick. The outer corky layer is either grey and firmly adherent, or buff, spongy and easily removed by the finger-nail.

The inner surface is light brown, finely striated and usually laminated, and, under a lens, exhibits numerous short, longitudinal, whitish lines (calcium oxalate crystals). The fracture is short and resinous. A smoothed, transverse section shows a thin, buff or grey cork, a pale brown cortex with scattered, whitish, calcium oxalate cells and narrow, brown, radial strips of phloem containing darker brown patches of fibres, separated by paler medullary rays which widen out slightly towards the cortex. It gives a red colour with ferric chloride solution. The taste is bitter.

The diagnostic **microscopical** characters are the small sclerenchymatous cells from the cork and the phelloderm; in the cortex, the elongated cells filled with acicular crystals of calcium oxalate; the scattered, isolated or grouped, phloem fibres; the secretion cells; the numerous narrow cells, each containing one longitudinally elongated, prismatic crystal of calcium oxalate (up to 120 microns long); the medullary rays, 2 cells wide in the inner part, widening outwards; the small, rounded starch grains about 3 to 10 microns in diameter.

Cusparia **contains** the bitter principle angosturin, a colourless, crystalline substance which is readily soluble in water, alcohol and ether. The bark also contains about 2·4 per cent. of the bitter, crystalline alkaloids, cusparine, galipine, galipoidine, and a fourth which awaits investigation. Cusparidine and cuspareine, alkaloids previously reported to be present, are probably mixtures of galipine and cusparine. About 1 per cent. of volatile oil and a glycoside, which yields a fluorescent substance when hydrolysed by heating with dilute sulphuric acid, are also present.

Substitutes.—Cusparia has been adulterated with nux vomica bark, which is different in appearance and distinguishable by the transverse section, which exhibits under the lens a distinct paler line of sclerenchymatous cells, separating the cortex from the phloem. This line of cells is never found in cusparia, which seldom contains any sclerenchymatous tissue, other than small isolated groups of bast fibres. Its characteristic structure serves to distinguish cusparia from other adulterants, such as copalchu bark (*Croton niveus* Jacq.), and Brazilian angostura bark (*L'senbeckia febrifuga* A. Juss.).

Standard.—Cusparia contains not more than 2 per cent. of foreign organic matter. Ash, not more than 7 per cent.

Cusparia, in powder (Pulvis Cuspariæ : Pulv. Cuspar.), contains the constituents and possesses the diagnostic microscopical characters of Cusparia, and complies with the limit for ash of the unground drug.

Action and Uses.—Cusparia is an aromatic bitter and is administered as an infusion. It is a constituent of "Angostura bitters," which also contains cinchona and other bitter substances.

Preparation

Infusum Cuspariæ Concentratum, B.P.C.—(Inf. Cuspar. Conc.)—Concentrated Infusion of Cusparia. 1 in 2½. When infusion of cusparia or Infusum Cuspariæ is prescribed, this concentrated infusion diluted with seven times its volume of distilled water may be dispensed. Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

CUSO**(Cuss.)****Kousso**

Kousso consists of the dried panicles of the fertilised, pistillate flowers of *Brayera anthelmintica* Kunth (Fam. Rosaceæ), a tree indigenous to North-Eastern Africa, and cultivated in Abyssinia.

The panicles are from 30 to 50 centimetres long, usually bound with a flexible stem and known in commerce as "hanks"; they have a characteristic dull reddish colour. The numerous branches, which are more or less covered with glands and shaggy hairs, are axillary to large bracts and bear many shortly-stalked flowers. "Loose kousso" consists of the broken panicles. The pistillate flower shows a cup-shaped, coarsely hairy receptacle, bearing upon its rim an epicalyx of 5 spreading sepals about 1 centimetre long, with prominent reddish or purplish veins, an inconspicuous inner calyx of brownish, shrivelled sepals bent inwards over a ring of aborted stamens, the corolla being caducous. One or two shrivelled, apocarpous carpels, with protruding styles and enlarged stigmas, are present. The odour is not marked, and the taste is bitter and acrid.

The diagnostic **microscopical** characters are the abundant, thick-walled, more or less lignified, frequently waved or curved, unicellular trichomes from the bracts, epicalyx and calyx, from 30 to 1200 microns long and from 6 to 20 microns wide; the unicellular, spherical heads, about 40 to 60 microns in diameter, of stalked, glandular trichomes; the small-celled parenchyma with numerous cluster-crystals of calcium oxalate, about 6 to 15 microns wide, and small calcium oxalate prisms, measuring from 3 to 4 microns; the lignified and pitted parquetry cells of the inner epidermis of the pericarp; the stellate cells of the spongy mesophyll of the sepals; the small spiral and annular vessels, up to 20 microns wide; the occasional, spherical pollen grains, 30 to 36 microns in diameter.

Kousso **contains** a yellow, amorphous body, kosotoxin. It also contains the inactive, colourless, crystalline bodies, protokosin and kosidin, as well as tannin and resin. Kosin of commerce is a mixture of two inactive, yellowish, crystalline bodies, α -kosin and β -kosin, which have been isolated from kousso but are believed to be decomposition products.

Standard.—Kousso contains not more than 10 per cent. of staminate flowers and other foreign organic matter.

Kousso, in powder (Pulvis Cusso : Pulv. Cuss.), contains the constituents and possesses the diagnostic microscopical characters of Cusso, and contains not more than 200 pollen grains per milligram.

Action and Uses.—Kousso is an anthelmintic used especially for tape-worm. It is **administered** as an infusion (Infusum Cusso, 1 to 16) but is less certain in its action than extract of male fern. Treatment should be preceded by the administration of 1 drachm doses of sodium bicarbonate thrice daily, and the dose, preceded by a saline purge, taken

on an empty stomach. It is sometimes preferable to divide the dose and to give from $\frac{1}{2}$ to 1 drachm every half-hour up to four doses. After some hours a further purge may be administered, although the natural action of the drug on the bowel usually renders this unnecessary. Collapse has been known to follow the use of kousso, but this is extremely rare. Kosotoxin, after absorption, increases spinal reflexes and later paralyses the motor nerves.

Dose.—8 to 16 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ ounce), made into an infusion.

CYDONIA

(Cydon.)

Quince

Synonyms—Cydoniæ Semen; Quince Seed.

Quince consists of the seeds obtained from a small tree, *Pyrus Cydonia* Linn. (Fam. Rosaceæ), which is cultivated in temperate Europe and South Africa. The fruit resembles a pear and contains five carpellary cavities in each of which a number of seeds are closely packed in two vertical rows.

The seeds are from 6 to 7 millimetres long and dark brown in colour; the two larger sides are flattened owing to mutual pressure in the fruit, and, of the other two sides, one is arched and the other often provided with a distinct ridge; they frequently adhere to one another by a white mucilage, which appears in flakes on the surface of the seeds and in the spaces between them; the seeds are pointed at one end, where the hilum occurs as a paler spot, but they are obtuse at the other extremity, where the chalaza is situated. Transverse sections of the seed show two firm, yellowish-white cotyledons and a very narrow endosperm. The kernel has a slightly bitter taste resembling that of bitter almond.

Quince **contains** about 20 per cent. of mucilage, which is contained in the epidermis of the seed coat. The cotyledons contain fixed oil (about 15 per cent.), proteins, and probably a small proportion of amygdalin and emulsin or some allied enzyme.

Action and Uses.—Quince is soothing and demulcent and is used in the form of Decoctum Cydoniæ (1 in 80) as an ingredient of, or as a basis for, lotions and creams. Mucilage of quince (Mucilago Cydoniæ, 1 in 25) forms a useful suspending agent for such liquids as tincture of benzoin when added to toilet preparations.

DAMIANA

(Damian.)

Damiana

Synonym—Turnera.

Damiana consists of the dried leaves of *Turnera diffusa* Willd. var. *aphrodisiaca* Urb. (Fam. Turneraceæ) and probably other species of *Turnera*, herbs indigenous to Texas and Mexico.

The leaves are pale green or yellowish-green in colour, about 10 to 25 millimetres long and 5 to 10 millimetres wide, broadly lanceolate and shortly petiolate. The margin is serrate, with three to six comparatively large teeth on each side; the surface is smooth, the veins pinnate and prominent on the under surface. There are frequently present amongst the leaves small quantities of reddish-brown, cylindrical twigs, yellowish, pentamerous flowers and small, yellowish-brown, spherical fruits containing numerous minute, yellow, crescent-shaped seeds. The odour and taste are aromatic.

The diagnostic **microscopical** characters are the upper epidermis, formed of cells with almost straight walls and without stomata; the lower epidermis, with somewhat wavy walls and abundant oval stomata; the presence of an isobilateral mesophyll; the simple, filiform, unicellular trichomes, up to 900 microns long, often undulating and bent near the base, with unthickened, strongly thickened walls and a warty surface; the numerous, small clusters and occasional prisms of calcium oxalate; the thin-walled, reddish-brown cork cells from the stem; the lignified parenchyma from the pith; a few stone cells, small vessels, and occasional starch grains up to 12 microns in diameter.

Damiana **contains** from 0.5 to 1 per cent. of a greenish volatile oil, having the odour of chamomile and a light brown, amorphous, bitter principle, damianin. It also contains two resins, 3 to 4 per cent. of tannin, gum, starch and fixed oil. It yields to alcohol (60 per cent.) from 18 to 26 per cent. of extractive.

Standard.—Damiana contains not more than 15 per cent. of its stems and not more than 3 per cent. of other foreign organic matter. Acid-insoluble ash, not more than 4 per cent.

Damiana, in powder (*Pulvis Damianæ* : *Pulv. Damian.*), contains the constituents and possesses the diagnostic microscopical characters of Damiana, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Damiana is a mild purgative and has been recommended for the treatment of sexual debility. It probably acts through its mildly irritant volatile oil causing increased peristalsis and stimulation of the genito-urinary tract during excretion, but no reliable observations on its action have been recorded. It may be **administered** in the form of extract in pills or liquid extract in mixtures.

Preparations

Extractum Damianæ, B.P.C.—(*Ext. Damian.*)—Extract of Damiana. A soft extract. Dose.—0.3 to 0.6 gramme (5 to 10 grains).

Extractum Damianæ Liquidum, B.P.C.—(*Ext. Damian. Liq.*)—Liquid Extract of Damiana. 1 in 1. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Mistura Damianæ Composita, B.P.C.—(*Mist. Damian. Co.*)—Compound Damiana Mixture. Each fluid drachm contains 15 minims of liquid extract of damiana, 1 minim of liquid extract of *nux vomica* and $2\frac{1}{2}$ grains each of the hypophosphites of calcium and sodium, in chloroform water. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Pilulæ Damianæ Compositæ, B.P.C.—(Pil. Damian. Co.)—Compound Damiana Pills. Each pill contains 2 grains of extract of damiana and $\frac{1}{10}$ grain each of dry extract of nux vomica and phosphorated suet. Dose—1 pill.

DATURÆ FOLIUM

(Datur. Fol.)

Datura Leaf

Synonym—Daturæ Folia

Datura leaf consists of the dried leaves and flowering tops of *Datura Metel* Linn (Fam. Solanaceae) an annual plant indigenous to India and also of *Datura innoxia* Miller, an annual indigenous to Mexico now growing freely in India and cultivated in England.

The leaves of *D. Metel* average about 10 centimetres long and 7 centimetres wide across the widest part; they vary considerably in outline, some being nearly cordate with few sinuses, whereas others have three or four coarse teeth on each half of the lamina; they appear nearly glabrous and are thin in texture. The leaves of *D. innoxia* are ovate or somewhat cordate and average about 12 centimetres in length and 7 centimetres in width; the margin is entire or with a few teeth, the apex acute and the surface densely pubescent. The leaves of both plants are green in colour; the flowers are white or lavender, funnel-shaped borne in the forks of the branches, about 8 centimetres long, and the ovary is ovate-conical and covered with stiff emergences. Datura leaf has a slight but unpleasant odour.

The chief **microscopical** features are the typical solanaceous stomata on both surfaces; the trichomes, which in *D. Metel* are of two kinds, covering and glandular, the former being frequently curved and having a basal cell which rarely exceeds 30 microns in diameter or 50 microns in length, and in *D. innoxia* are of three kinds, smooth or slightly warty long-stalked glandular trichomes terminating in a single spherical secreting cell, short club-shaped glandular trichomes, and warty covering trichomes the basal cell of which is never more than 50 microns in diameter but frequently more than 50 microns in length. Cluster-crystals of calcium oxalate and large crystalline masses of unknown composition occur in the mesophyll of the leaves.

Datura leaf **contains** hyoscyine, which occurs to the extent of about 0.25 to 0.55 per cent.; traces only of hyoscyamine and atropine are present.

Standard.—Datura leaf contains not more than 3 per cent. of foreign organic matter and not more than 20 per cent. of stems, fruits and flowers. Acid-insoluble ash, not more than 4 per cent.

Datura leaf, in powder (Pulvis Daturæ Folii: Pulv. Datur. Fol.), contains the constituents and possesses the diagnostic microscopical characters of Daturæ Folium, and complies with the limit for acid-soluble ash of the unground drug.

Action and Uses.—*Datura* leaf is used in India for the same purposes as belladonna and stramonium.

DATURÆ SEMEN

(Datur. Sem.)

Datura Seed

Datura seed consists of the dried seeds of *Datura Metel* Linn. (Fam. Solanaceæ), an annual plant indigenous to India.

The seeds are auriform in shape, flattened, from about 4 to 5 millimetres in length, 3 to 4 millimetres in width and 1 millimetre in thickness; the margin is wavy, thickened, and shows a triple ridge; the seed coat, which is yellowish-brown, thick and finely pitted, encloses a narrow, translucent endosperm and a curved embryo; the hilum is prominent owing to the presence of a strophiole which extends from the acute end of the seed to about the middle of the flattened edge. The seeds have no odour but possess a bitter taste.

The diagnostic **microscopical** characters are the large, lignified cells of the seed coat, somewhat oval in outline, mostly about 180 microns long and 90 microns wide, with very thick cell walls, the basal walls being conspicuously pitted; the drops of fixed oil, and aleurone grains.

Datura seed **contains** hyoscine, about 0.2 per cent, and a small quantity of hyoscyamine. Resin and fixed oil are also present.

Standard.—*Datura* seed contains not more than 2 per cent. of foreign organic matter.

Action and Uses.—*Datura* seed is used in India for the same purposes as stramonium seed. The tincture (*Tinctura Daturæ Seminis*, 1 in 4), has been used as a sedative in the treatment of asthmatic coughs in doses of 0.3 to 1 millilitre (5 to 15 minims).

DERRIS

(Derr.)

Derris

Synonyms—Tuba Root; Aker-tuba.

Derris consists of the dried rhizome and roots of *Derris elliptica* (Roxb.) Benth. and *D. malaccensis* Prain (Fam. Leguminosæ), climbing plants indigenous to Malay and the East Indies and cultivated in the Federated Malay States, Sumatra, Johore, Sarawak and Singapore.

The roots, a number of which are sometimes attached to a short piece of the rhizome, occur in pieces up to 2 metres in length, and vary in thickness from fine rootlets up to 8 millimetres in diameter; they are very flexible, hard and tough, and have a fibrous fracture. Externally, they are greyish-brown to reddish-brown, with numerous fine, longitudinal

furrows; on the thicker pieces, many elongated scars occur arranged in irregularly spaced ring formation. The transverse section exhibits a brown bark and a wood varying in colour from cream to pale brown, and in the larger pieces showing three or four concentric circles. The odour is slight, but aromatic, and the taste is at first slightly bitter, but, on chewing, a very persistent feeling of numbness develops in the tongue, and gradually extends to the throat. The smaller roots are considered to contain the greater amount of active principle, which probably reaches its maximum strength in roots which are about two years old.

Derris contains up to 10 per cent. of the non-volatile, colourless, crystalline substance, rotenone ($C_{23}H_{22}O_6$, melting-point, about 163° , optical rotation in benzene, about -233°), at one time known as tubatoxin. Three other crystalline substances, deguelin, tephrosin and toxicarol, have also been isolated. It yields to ether from about 7 to 25 per cent. of extractive. The active constituents are soluble in acetone, benzene, chloroform, ether and some other organic solvents, and slightly soluble in alcohol and mineral oils. Alkalis and prolonged boiling with certain solvents cause a loss of activity due to chemical change; pyridine is particularly active in this respect. Benzene and carbon tetrachloride give relatively stable solutions, but rotenone crystallises from these solutions with solvent of crystallisation. The active principles are insoluble in water, weak acids and alkalis.

Substitutes.—Other species of *Derris*, namely, *D. uliginosa* Benth., *D. involuta* Sprague, *D. chinensis* Benth. and *D. koolgibberah* F. M. Bailey, grow wild in Australia and are said to contain rotenone. The roots, rhizome and stem of *D. uliginosa* Benth. are imported; samples consist mainly of the stem, in pieces 10 to 25 centimetres long and 8 to 25 millimetres thick. Portions are commonly found in which two stems have become intertwined. The bark is rusty greyish-brown, very rough, with prominent longitudinal ridges and furrows, numerous reddish-brown warts, and bears the remains of buds protruding at intervals. The outer layer forms grey, papery scales partially detached from the surface. The wood is very tough and hard. The transverse section exhibits a bark, light-coloured near the outside but darker near the wood; the wood is yellowish to brown, porous and without marked radial structure, and the pith is small. It contains a much smaller proportion of active principle than either *D. elliptica* or *D. malaccensis*. *Lonchocarpus Nicou* DC., cube root, and other species of *Lonchocarpus* (Fam. Leguminosæ), indigenous to parts of South America and cultivated there, contain rotenone in the stem and root.

Standard.—Derris contains not less than 2 per cent. of rotenone. Ash, not more than 6 per cent. Acid-insoluble ash, not more than 2 per cent.

Derris, in powder (Pulvis Derridis : Pulv. Derr.), contains the constituents of Derris, and complies with the standard for the unground drug.

Assay.—Extract 50 grammes, in No. 60 powder, by continuous extraction with carbon tetrachloride for at least twelve hours. Evaporate the extract to about 25 millilitres and transfer while still hot to a flat-bottomed glass dish, washing the flask with 5 millilitres of warm carbon tetrachloride and adding the washings to the dish. Cover the dish and

set aside in a cool place to allow the rotenone-carbon tetrachloride compound to crystallise, hastening the crystallisation, if necessary, by seeding with a small crystal of rotenone and cooling the solution by means of ice. Transfer the crystals to a tared Gooch crucible, wash with 20 millilitres of ice-cold carbon tetrachloride, remove the excess of solvent as far as possible by suction, and dry the crystals spontaneously or in an air oven at a temperature not exceeding 40°; each gramme of the crystals is equivalent to 0.719 gramme of rotenone.

Uses.—Derris is used extensively in horticulture and agriculture as an insecticide, and is of special value in the control of the warble fly. The powdered root is used as a dusting powder, but is more economically used mixed with an inert powder, such as kaolin or talc; alternatively it may be mixed with soft soap and water, and used in the form of a spray. One pound of the root with 4 ounces of soft soap and sufficient water to make 1 gallon is a useful insecticidal wash effective against a fairly wide range of pests. The powder produces unpleasant symptoms when inhaled, but is probably harmless to human beings and warm-blooded animals.

DEXTROSUM

(Dextros.)

Dextrose

Synonym—Medicinal Glucose (Anhydrous).

Dextrose is a dextrorotatory monosaccharide, and may be obtained by the purification of commercial lump glucose, which is produced by the hydrolysis of starch. It occurs as a white, crystalline or granular, odourless powder with a sweet taste. When heated, it swells and burns, evolving an odour of burnt sugar. It reduces Fehling's solution on warming, and gives a silver mirror when warmed with silver ammonio-nitrate solution. The mutarotation is catalysed by the addition of traces of hydrochloric acid or alkali.

The pure monohydrate is also available for medicinal purposes; it is usually supplied under the name of medicinal glucose or dextrose monohydrate, and is the form generally employed for oral administration. Various commercial grades of glucose are obtainable containing a variable amount of water, together with maltose and dextrans; they occur in hard, lumpy masses, containing 30 to 80 per cent. of dextrose, or in the form of syrup.

Soluble in water (more than 1 in 1), alcohol (90 per cent.) (about 1 in 50), boiling alcohol (90 per cent.) (about 1 in 5) and glycerin.

Standard, B.P.—Dextrose loses, on drying at 105°, not more than 2.5 per cent. of its weight. Ash, after ignition and re-ignition with sulphuric acid, not more than 0.1 per cent. Specific rotation of a

well-boiled 10 per cent. w/v solution of the dried substance, not less than $+52^{\circ}$. Arsenic limit, 1 part per million. Lead limit, 2 parts per million. It complies also with limit tests for acidity, less soluble sugars and dextrans, chloride, sulphate and sulphite.

Action and Uses.—Dextrose is administered either orally or parenterally in a number of conditions involving a carbohydrate deficiency, since it presents carbohydrate in a form that is readily absorbed without further digestive action. In debilitating and infectious diseases, where the food intake is insufficient, dextrose is given orally, or a 10 to 20 per cent. w/v solution is administered by intravenous or intramuscular injection or by enema. By sparing the protein from destruction and assisting in the metabolism of fats, dextrose counteracts acidosis or prevents its onset. It is, therefore, given prior to general anæsthetics and for post-operative acidosis, delayed chloroform poisoning, the vomiting of pregnancy and recurrent vomiting in children, and for sea or train sickness. In pneumonia, diphtheria and other infectious diseases, dextrose, in addition to providing nutriment, counteracts the toxæmia. It also prevents toxæmia and protects the liver from damage in poisoning due to overdosage of, or idiosyncrasy to, cinchophen, arsphenamine, phosphorus and the heavy metals. For the treatment of shock and collapse following surgical operations or accidents, the intravenous injection of dextrose solution causes an increase in the blood pressure and amplitude of the pulse. Alternatively, it may be given by subcutaneous injection or by rectal enema.

Dextrose solution is also used in osmotherapy, in which a strongly hypertonic solution (25 per cent. w/v) is injected intravenously to cause a temporary reduction in the fluid pressure in the tissues by the withdrawal of water. Such a procedure is of value in relieving intracranial pressure in hydrocephalus and meningitis, and prior to intracranial operations, also to promote drainage of the accessory nasal sinuses. Hypertonic solutions of dextrose have been used as dressings to wounds and ulcers, for the purpose of promoting by osmosis an increased flow of lymph to the tissues. Solutions of 20 to 25 per cent. w/v have been used for local application to the nasal mucous membrane in the treatment of ozena and atrophic rhinitis. Dextrose is added to spinal anæsthetic solutions to increase the specific gravity and so localise the anæsthetic action.

Dextrose is largely used in infant feeding to augment the carbohydrate content of cows' milk. Being rapidly absorbed, it is readily assimilated and not likely to give rise to intestinal fermentation. Solutions of dextrose (50 to 60 per cent. w/v), or dextrose with sodium chloride (20 to 30 per cent. w/v), have been used by injection in the treatment of varicose veins. The advantage of such solutions is their innocuous character. They are, however, not reliable sclerosing solutions, and the clot formed is liable to recanalisation.

For intravenous injection, the concentration of the solution varies, according to the effect desired, from 5 to 25 per cent. w/v, the usual

strength being 10 per cent. A 5 per cent. w/v solution is approximately isotonic, and a 25 per cent. solution, which is strongly hypertonic, is used when an osmotic effect is desired. Solutions for intravenous injection should be freshly prepared and carefully filtered. The solution should be kept slightly above body temperature, and the injection made very slowly. A solution for **injection** is sterilised by heating in an autoclave, by tyndallisation, or by filtration. For administration as a retention enema, a 5 per cent. w/v solution is generally used.

DEXTRINUM.—Dextrin, or British gum, is an intermediate product in the ultimate hydrolysis of starch. It is made by heating starch, which has been moistened with a small quantity of dilute nitric acid and dried, at 110° to 115°. Dextrin dissolves in water, forming a mucilaginous solution which is used as an adhesive and for stiffening surgical bandages. Pure dextrin does not reduce Fehling's solution. Mixtures containing dextrin, glucose, lactose and maltose are administered as carbohydrate foods in the nutrition of infants. Mineral salts, especially iron salts, and preparations of vitamins B₁, B₂ and D, are sometimes added to the food.

Preparation

Liquor Dextrosi et Sodii Chloridi, B.P.C.—(Liq. Dextros. et Sod. Chlor.)—Dextrose and Sodium Chloride Solution. *Syn.*—Glucose-saline Solution. A sterile aqueous solution containing 5 per cent. w/v of dextrose and 0.9 per cent. w/v of sodium chloride.

DIAMORPHINÆ HYDROCHLORIDUM

(Diamorph. Hydrochlor.)

Diamorphine Hydrochloride

Diamorphine hydrochloride, or diacetylmorphine hydrochloride, is the hydrochloride of the diacetyl derivative of morphine, and may be obtained by the action of acetic anhydride on morphine. It occurs as a colourless, odourless, crystalline powder with a bitter taste. On the addition of a small quantity of diamorphine hydrochloride to a few drops of nitric acid, a yellow colour is produced, which changes to greenish-blue on warming, and again becomes yellow on cooling. When a small quantity of a 5 per cent. w/v solution of diamorphine hydrochloride in alcohol is warmed with half its volume of sulphuric acid, the odour of ethyl acetate is developed. Diamorphine hydrochloride dissolves in sulphuric acid, giving a colourless solution; when a small quantity of the solution is warmed on a water-bath, cooled, and diluted with water, a deep blue colour is produced on the addition of a solution of potassium ferricyanide containing a trace of ferric chloride solution.

Diamorphine, or its salts, may be distinguished from ethylmorphine and from benzylmorphine by mixing with a few drops of a mixture of equal parts of sulphuric acid and nitric acid; a greenish-yellow colour is produced, which is not changed on warming. Diamorphine hydrochloride should be **stored** in a well-closed container away from light.

Soluble in water (1 in 2), alcohol (90 per cent.) (1 in 11); insoluble in ether; readily soluble in chloroform.

Standard, B.P.—Diamorphine hydrochloride has a melting-point of 229° to 233°. Loss on drying at 100°, not more than 4.5 per cent. Ash, not more than 0.1 per cent. It complies also with a limit test for morphine.

Action and Uses.—Diamorphine resembles morphine in its action in allaying peripheral irritation and relieving pain. It acts more strongly on the respiration than morphine, and is a more powerful drug. It is employed to relieve irritable cough, especially in phthisis, laryngitis, asthma and bronchitis with dyspnoea. Diamorphine has an advantage over morphine in that it has less tendency to cause gastric disturbance and constipation. It is easier to become addicted to the habit of taking diamorphine than morphine, and the effects of addiction are worse, greater mental and moral deterioration occurring. The drug is taken either by injection or as snuff. Diamorphine is partly oxidised in the body and partly excreted by the kidneys.

Diamorphine hydrochloride is best **administered** in the form of elixir, linctus, or pastille, or by hypodermic injection. A solution for **injection** may be sterilised by tyndallisation or by filtration, and the containers must comply with the tests for limit of alkalinity of glass. The hydrochloride should be given in neutral solution; it is **incompatible** with acids and alkalis, by which it is readily decomposed. In cases of **poisoning** by diamorphine and its salts, the antidotes for morphine should be administered.

Dose.—0.0025 to 0.008 gramme ($\frac{1}{200}$ to $\frac{1}{125}$ grain).

Preparations

Elixir Diamorphinae et Pini Compositum, B.P.C.—(Elix. Diamorph. et Pini Co.)—Compound Elixir of Diamorphine and Pine. Each fluid drachm contains approximately $\frac{1}{16}$ grain of diamorphine hydrochloride and $\frac{1}{8}$ grain of terpin hydrate, with oil of pumilio pine, alcohol (90 per cent.), glycerin and sucrose, coloured with compound solution of tartrazine. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Elixir Diamorphinae et Terpini, B.P.C.—(Elix. Diamorph. et Terpin.)—Elixir of Diamorphine and Terpin. Each fluid drachm contains approximately $\frac{1}{8}$ grain of diamorphine hydrochloride and $\frac{1}{4}$ grain of terpin hydrate, with alcohol (90 per cent.), glycerin and syrup of wild cherry. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Elixir Diamorphinae et Terpini cum Apomorphina, B.P.C.—(Elix. Diamorph. et Terpin. c. Apomorph.)—Elixir of Diamorphine and Terpin with Apomorphine. Each fluid drachm contains $\frac{1}{16}$ grain of diamorphine hydrochloride and $\frac{1}{8}$ grain of terpin hydrate, with apomorphine hydrochloride, alcohol (90 per cent.), glycerin and syrup of wild cherry. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Glycerinum Diamorphinae, B.P.C.—(Glyc. Diamorph.)—Glycerin of Diamorphine. Each fluid drachm contains about $\frac{1}{16}$ grain of diamorphine hydrochloride, with chloroform, alcohol (90 per cent.), concentrated acid infusion of roses, syrup, distilled water and glycerin. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Linctus Diamorphinæ, B.P.C.—(Linct. Diamorph.)—Linctus of Diamorphine. Each fluid drachm contains about $\frac{1}{2}$ grain of diamorphine hydrochloride with tincture of hyoscyamus, spirit of chloroform, syrup of wild cherry, syrup of tolu and glycerin. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Linctus Diamorphinæ Camphoratus, B.P.C.—(Linct. Diamorph. Camph.)—Camphorated Linctus of Diamorphine. Each fluid drachm contains $\frac{1}{10}$ grain of diamorphine hydrochloride and $\frac{1}{2}$ minim of liquid extract of ipecacuanha, with camphor, benzoic acid, oil of anise, tincture of squill and syrup. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Linctus Diamorphinæ cum Ipecacuanha, B.P.C.—(Linct. Diamorph. c. Ipecac.)—Linctus of Diamorphine with Ipecacuanha. Each fluid drachm contains $\frac{1}{10}$ grain of diamorphine hydrochloride and $\frac{1}{2}$ minim of liquid extract of ipecacuanha, with tincture of hyoscyamus, spirit of chloroform, syrup of tolu, syrup of wild cherry and glycerin. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Linctus Diamorphinæ et Scillæ, B.P.C.—(Linct. Diamorph. et Scill.)—Linctus of Diamorphine and Squill. Each fluid drachm contains $\frac{1}{10}$ grain of diamorphine hydrochloride and $\frac{1}{20}$ grain of sodium antimonytartrate, with liquid extracts of senega and squill, glycerin and syrup. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Linctus Diamorphinæ et Thymi, B.P.C.—(Linct. Diamorph. et Thym.)—Linctus of Diamorphine and Thyme. Each fluid drachm contains $\frac{1}{10}$ grain of diamorphine hydrochloride, and $\frac{1}{10}$ grain of apomorphine hydrochloride, with liquid extract of thyme, solution of tolu and glycerin. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Pastilli Diamorphinæ et Pini Compositus, B.P.C.—(Pastill. Diamorph. et Pini Co.)—Compound Diamorphine and Pine Pastilles. Each pastille contains $\frac{1}{10}$ grain of diamorphine hydrochloride, $\frac{1}{4}$ minim of oil of pumilio pine and $\frac{1}{4}$ grain of terpin hydrate.

DIASTASUM

(Diastas.)

Diastase

Synonym—Amylase.

Diastase is an impure enzyme obtained by precipitation with alcohol from an infusion of malt prepared at a temperature not exceeding 60°. The diastase may be purified by re-precipitation. It occurs as a whitish or yellowish, amorphous powder. It is not precipitated by calcium hydroxide, lead acetate, or barium hydroxide solutions. It has the power of converting starch into maltose and dextrose, the optimum temperature being about 55°.

The methods of assay may be summarised under two heads:—
1.—The determination by means of Fehling's solution of the reducing sugars produced by the action of the enzyme on a known quantity of starch. 2.—The time taken for the complete conversion of a known quantity of starch, the end of the reaction being indicated by the solution ceasing to give a reddish colour with iodine. The strength is expressed by the number of parts of starch converted by one part of diastase, but unless details of the method of assay are given, statements regarding the strengths of commercial samples are of little value. The

activity of the enzyme is destroyed at high temperatures and also in the presence of acid or alkali.

Almost entirely **soluble** in water; insoluble in alcohol.

Action and Uses.—Diastase acts as a sugar-forming ferment and is useful in certain gastric disorders. It may be mixed with starchy foods to assist their conversion into soluble sugar, or it may be taken during a meal, mixed with a little milk or in a cachet. It is employed in amylaceous dyspepsia, sometimes with pepsin and capsicum. The optimum pH for the action of diastase is 5.2. Its action is decreased in more acid or more alkaline media and at pH 1.7 it is irreversibly inactivated. The presence of proteins, which act as buffers, prevents the hydrochloric acid secreted during the early stages of digestion from reaching too low a pH. This, combined with the fact that there is relatively no movement in the cardiac end of the stomach, allows diastatic digestion to proceed for about thirty minutes after ingestion of food.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

Preparation

Pulvis Pepsini Compositus, B.P.C.—(Pulv. Pepsin. Co.)—Compound Pepsin Powder. Pepsin, about 1 in 6, pancreatin, 1 in 10, and diastase, 1 in 100, with lactic acid, hydrochloric acid and lactose. Dose.—0.6 to 2 grammes (10 to 30 grains).

DIATOMITE

(Diatomit.)

Diatomite

Synonyms—Purified Siliceous Earth; Purified Kieselguhr.

Diatomite is obtained from siliceous deposits consisting chiefly of minute, structural forms of the skeletal remains, or frustules, of diatoms—minute, unicellular organisms belonging to the Diatomaceæ. Immense beds from 40 to 50 feet deep occur in Aberdeenshire, also in Germany, Virginia and elsewhere. Specimens from different localities vary considerably, not only in appearance, but in the species of diatoms present and in the matter with which the diatomaceous residue is associated. The crude material is air-dried and crushed, incinerated to destroy organic matter, boiled with dilute hydrochloric acid, washed with water and dried. It consists chiefly of silica and occurs as a bulky, but odourless powder, white to pale buff in colour. **Microscopically**, it is seen to consist of various forms of diatomaceous skeletons. There is no quantitative method capable of discriminating between this type of silica and inorganic crystalline silica in the form of quartz, sand, silt, &c., but an authentic sample should possess the following characteristics. Mounted in olive oil and viewed under the low power of a microscope, the diatoms become almost invisible whilst inorganic silica becomes pronounced; the latter should not be present to any appreciable

extent. By careful elutriation the diatoms may be washed away, leaving only a small residue of grit. The apparent density, as determined on the substance in No. 30 powder, dried at 105°, in a glass cylinder of about 2 centimetres diameter and 6 centimetres depth, should be higher than 0.4. It absorbs about 4 times its own weight of water without becoming fluid. In its natural state, the deposit contains varying proportions of organic matter (0.5 to 20 per cent.), as well as sand, clay and iron oxide. It should be **stored** in well-closed containers.

Soluble in alkalis, insoluble in acids except hydrofluoric acid.

Standard.—Diatomite loses on ignition not more than 10 per cent. of its weight (limit of moisture), and is not darkened in colour (limit of organic impurities). Shake 2 grammes with 40 millilitres of dilute hydrochloric acid for fifteen minutes and filter; 20 millilitres of the filtrate, evaporated to dryness and ignited, leaves not more than 0.01 gramme of residue. Boil 2 grammes with 20 millilitres of water for ten minutes, filter and dilute to 100 millilitres; the solution is neutral to litmus, and 50 millilitres complies with the limit test for iron. 2 grammes produces no effervescence on the addition of 50 millilitres of dilute hydrochloric acid (limit of carbonate), and on boiling, filtering and diluting to 100 millilitres, 50 millilitres of the solution complies with the limit test for sulphates.

Uses.—Diatomite is used in the preparation of dusting powders, usually with boric acid and zinc oxide or stearate. It is also employed as a basis for disinfectant powders and for dentifrices—powder or paste—containing phenol or boric acid. It may be used as a pill excipient for volatile oils and mixtures which liquefy (such as menthol and phenol), the mass being prepared with hydrous wool fat or glycerin of tragacanth. Diatomite is also used as a filtering medium for clarifying syrups, waters and other liquids; for this purpose the powder should be triturated with a little of the liquid before being added to the bulk of liquid to be filtered.

DICHLORAMINA

(Dichloram.)

Dichloramine

Synonym—Dichloramine-T.

Dichloramine is *p*-toluenesulphondichloroamide, $\text{CH}_3 \cdot \text{C}_6\text{H}_4 \cdot \text{SO}_2 \cdot \text{NCl}_2$, and may be obtained by the action of hypochlorites upon *p*-toluenesulphonamide. It occurs as pale yellow crystals, or as a yellowish, crystalline powder, having an odour resembling that of chlorine. It gradually decomposes on exposure to air, with loss of chlorine; it is also decomposed by alcohol. Melting-point, about 78°; at higher temperatures, sudden decomposition takes place. It liberates

bromine from neutral sodium bromide solution (distinction from chloramine), and liberates chlorine when mixed with sulphuric acid. It should be **stored** in well-closed glass containers in a cool place, and protected from light.

Soluble in chloroform (about 1 in 1), benzene (about 1 in 1), carbon tetrachloride (about 1 in 3), glacial acetic acid, chlorinated eucalyptol and chlorinated paraffin; almost insoluble in water.

Standard.—Dichloramine contains not less than 93 per cent. of $C_7H_7O_2NCl_2S$. To 1 gramme add 5 millilitres of alcohol (90 per cent.), warm until interaction ceases, evaporate the resulting solution to dryness, and ignite; the residue weighs not more than 0.001 gramme (limit of inorganic matter). 1.0 gramme dissolved in 5 millilitres of chloroform forms a clear solution. 0.1 gramme added to 1 millilitre of sulphuric acid evolves chlorine, but does not colour the acid more than faintly yellow (limit of readily carbonisable substances).

Assay.—Weigh accurately about 0.2 gramme, and dissolve in 40 millilitres of glacial acetic acid in a dry, glass-stoppered bottle. Add 3.5 grammes of potassium iodide dissolved in 120 millilitres of water, allow to stand for ten minutes, and titrate the liberated iodine with N/10 sodium thiosulphate; each millilitre of N/10 sodium thiosulphate is equivalent to 0.006001 gramme of $C_7H_7O_2NCl_2S$.

Action and Uses.—Dichloramine is a powerful antiseptic, and is used in oily solution. A 2 per cent. solution in a mixture of 1 part of chlorinated eucalyptol, or chlorinated oil of eucalyptus, and 4 parts of chlorinated paraffin has been used for disinfecting the naso-pharynx of meningococcus carriers, and in the treatment of gonorrhœa.

DICHLORETHYLENUM

(Dichlorethylen.)

Dichlorethylene

Dichlorethylene, or acetylene dichloride, $ClHC:CHCl$, may be made by controlled interaction of acetylene and chlorine, or by the action of iron on a mixture of tetrachlorethane and water. Dichlorethylene is a mixture of two stereoisomerides, boiling respectively at 48° and 60° . It is a heavy, mobile liquid, with an ethereal but slightly acid odour. Specific gravity, about 1.30. It decomposes in the presence of air, light and moisture, forming hydrochloric acid and chlorine, which it is liable to contain. It may be purified by shaking with ammoniacal silver nitrate solution and separating, drying over quicklime, and distilling. Pure dichlorethylene has practically no action on metals with the exception of silver. Dichlorethylene dissolves rubber, fats, phenol, camphor, iodoform, and formaldehyde, and to a slight extent, alcohol and ether. It also dissolves bromine, forming a

reddish-brown solution, and iodine, forming a reddish-violet solution; the bromine solution is slowly decolourised, the halogen forming an additive compound. Dichlorethylene decolourises potassium permanganate solution. It should be **stored** in small, completely-filled bottles in a dark place.

Insoluble in water.

Uses.—Dichlorethylene has been employed as a solvent of iodine for skin sterilisation previous to operations. For this purpose, a 2·5 per cent. solution is recommended, which is approximately saturated. It may cause skin irritation.

DIGITALINUM

(Digitalin.)

Digitalin

Synonym—Digitalinum Purum Germanicum.

Digitalin is a standardised mixture of glycosides from the seeds of *Digitalis purpurea* Linn. (Fam. Scrophulariaceæ). It contains digitalinum verum, $C_{36}H_{56}O_{14}$, a definite, physiologically-active glycoside, together with a large proportion of water-soluble glycosides, concerning the nature of which little is known, and two physiologically-inactive glycosides, digitonin, $C_{55}H_{90}O_{29}$, and gitonin, $C_{49}H_{80}O_{28}$. Digitalis seed does not contain digitoxin or gitoxin. Digitalin may be prepared from the seed by extraction with alcohol and purifying the product obtained on evaporation by treatment with lead acetate and subsequent precipitation with tannic acid. After removal of the tannic acid, the crude digitalin is washed with ether and dried at a low temperature. The product, which may show considerable variation in activity, is assayed by the biological assay of powdered digitalis and its potency compared with the international standard digitalis, of which 0·1 gramme is taken to have an amount of activity described as 1 unit. It is then adjusted to contain 80 units per gramme by mixing with a suitable diluent such as lactose. Digitalin is a yellowish-white powder, which is free from odour but has an intensely bitter taste. The aqueous solution is neutral, and froths when shaken. When a solution of 0·001 gramme of digitalin in 1 millilitre of glacial acetic acid containing a trace of ferric chloride is superimposed upon 1 millilitre of sulphuric acid, a reddish band is produced.

Very **soluble** in water and alcohol; very sparingly soluble in chloroform and ether.

Standard.—Digitalin, when tested by the method of the British Pharmacopœia for the biological assay of *Digitalis Pulverata*, possesses 80 units of activity (equivalent to the activity of 8 grammes of the international standard digitalis powder) in 1 gramme.

Action and Uses.—Digitalin is much less active than digitoxin, but is not cumulative. On account of its ready solubility in water, it is employed in the preparation of solutions for injection and tablets. Solutions of digitalin for **injection** may be sterilised by tyndallisation or by filtration, and should be stored protected from light. This standardised digitalin should be dispensed when digitalin is prescribed without qualification, and it should be carefully distinguished from digitoxin (digitaline cristallisée). In cases of **poisoning** by digitalin, the antidotes described under *Digitalis Folium* should be employed.

Dose.—For a single administration, 0.03 to 0.06 gramme ($\frac{1}{2}$ to 1 grain); for repeated administration, 0.004 to 0.012 gramme ($\frac{1}{16}$ to $\frac{1}{5}$ grain), by subcutaneous injection.

Preparation

Injectio Digitalini, B.P.C.—(Inj. Digitalin.)—Injection of Digitalin. Each millilitre (15 minims) contains 0.03 gramme of digitalin, which is equivalent to about $2\frac{1}{2}$ units of activity. **Dose.**—For a single administration, 1 to 2 millilitres (15 to 30 minims), by subcutaneous injection; for repeated administration, 0.2 to 0.4 millilitre (3 to 6 minims), by subcutaneous injection.

DIGITALIS FOLIUM

(Digit. Fol.)

Digitalis Leaf

Synonyms—*Digitalis*; Foxglove Leaf.

Digitalis leaf consists of the dried leaves obtained from the foxglove, *Digitalis purpurea* Linn. (Fam. Scrophulariaceæ), a biennial herb widely distributed throughout Europe and common in England. The leaves are rapidly dried at 55° to 60° as soon as possible after collection. Digitalis leaf should be **stored** in well-closed containers and protected from moisture.

The dried leaves are brittle, greyish-green in colour, about 10 to 30 centimetres long and 4 to 10 centimetres wide, ovate-lanceolate to broadly-ovate and petiolate. The lamina has an irregularly crenate or serrate margin, a decurrent base, and subacute apex. The upper surface is hairy, the lower surface usually densely pubescent and marked by a reticulation of raised veinlets. The leaves have a distinctly bitter taste.

The diagnostic **microscopical** characters are the hairs, of two kinds, simple hairs usually 3 to 5 cells long, bluntly pointed and finely warty, and glandular hairs, consisting usually of a unicellular or, more rarely, biciliate pedicel bearing a unicellular or bicellular glandular head; the stomata, which are more numerous on the lower than the upper surface, having no special subsidiary cells; the wavy-walled epidermal cells of the lower surface; the large water-pores, one or occasionally two being situated at the apex of most of the teeth; the presence of calcium oxalate crystals and of sclerenchymatous elements.

Digitalis contains several glycosides, to which its physiological activity is due; of these, digitoxin, $C_{41}H_{64}O_{13}$, and gitoxin, $C_{41}H_{64}O_{14}$, have been obtained crystalline. A third glycoside, $C_{47}H_{74}O_{18}$, is described as having the composition of digitoxin with the addition of one molecule of dextrose; it is hydrolysed by the enzymes of the leaf into digitoxin and dextrose. The remaining glycosides have not been obtained in a state approaching purity; they are amorphous and more soluble than the crystalline glycosides. The latter are very sparingly soluble in water, but become more soluble in the presence of the amorphous glycosides. Distinctive names have been given to various mixtures, but only the two above-mentioned glycosides are definite substances. Gitalin and digtalein are mixtures of indefinite composition. Anhydrogitalin is a crude form of gitoxin. Digitalis seeds do not contain digitoxin or gitoxin, but contain a closely related glycoside, digitalinum verum, $C_{36}H_{56}O_{14}$, associated with a large proportion of water-soluble glycosides and two physiologically-inactive glycosides, digitonin, $C_{55}H_{90}O_{29}$, and gitonin, $C_{49}H_{80}O_{28}$. Digitalinum verum is not crystalline, but it forms crystalline derivatives. A standardised mixture of glycosides prepared from the seeds is known as digitalin, or digitalinum purum germanicum (see Digitalinum).

Substitutes.—Digitalis leaf, especially in the crushed or powdered state, is occasionally adulterated, leaves of the following plants having been substituted for the true drug:—Mullein leaves, the leaves of *Verbascum Thapsus* Linn., are woolly and bear branching candelabra hairs; comfrey leaves, from *Symphytum officinale* Linn., are lanceolate or ovate in shape and bear isolated stiff hairs; primrose leaves, from *Primula vulgaris* Huds., are nearly spatulate; they have straight, lateral veins, dividing near the margin. The leaves of the ploughman's spikenard, from *Inula Conyza* DC., have entire or dentate margins with horny points to the teeth. In elecampane leaves the lower lateral veins are not decurrent. Spanish foxglove leaves, from *Digitalis Thapsi* Linn., are distinguished by their greyish-green or yellowish-green colour, by the presence on both surfaces of numerous glandular trichomes with unicellular heads and 3- to 4-celled stalks, by the presence of pericyclic fibres and a few small prisms of calcium oxalate and by the absence of non-glandular trichomes. They are said to be more active than the leaves of *D. purpurea*. The leaves of *D. lutea* Linn., a native of Southern and Western Europe and cultivated in America, are sessile, about 10 to 28 centimetres long and 3 to 6 centimetres wide, oblanceolate, with an irregularly dentate or seriate margin, which is fringed with long, non-glandular trichomes in the basal half of the leaf, which is otherwise glabrous.

Standard, B.P.—Digitalis leaf contains not more than 2 per cent. of foreign organic matter. Loss on drying at 100° , not more than 8 per cent. Acid-insoluble ash, not more than 5 per cent.

Digitalis leaf in powder, contains the constituents and possesses the diagnostic microscopical characters of Digitalis Folium, and complies with the limits for moisture and ash of the unground drug. When powdered digitalis leaf is prescribed, the standardised powder Digitalis Pulverata, must be used.

Action and Uses.—Digitalis increases the activity of all forms of muscle tissue, but more especially that of the heart and arterioles. It exerts a double action on the heart; the diastole is prolonged, giving, in moderate doses, more time for complete filling and the efficiency of systole is much increased, so that, in spite of the

slowing, the output of blood per minute is augmented. The arterial system is filled, and the venous pressure falls as the blood finds an easy outlet into the empty heart. This redistribution of blood in the patient suffering from cardiac failure is shown by the shrinking of the swollen liver, the absorption of œdema with diuresis and the relief of pulmonary stasis and dyspnœa. Digitalis exerts its most pronounced effect on the heart in mitral disease with dilatation and passive venous congestion. Here, the action of the heart is almost always very rapid, and digitalis acts by prolonging diastole and so resting the muscle; it also improves systole and forces more blood through the coronaries, thus improving the nutrition of the heart; perhaps for this reason an irregular heart becomes regular. Digitalis benefits most patients in whom the auricles are fibrillating; here also, it acts by improving the nutrition of the heart and by causing a partial heart-block.

Perhaps the greatest use of digitalis is in auricular fibrillation. In this condition, a large number of feeble auricular beats are imperfectly transmitted to the ventricles, and it is suggested that digitalis, by depressing conductile tissue, allows only a few of these impulses to get through. By its action, the ventricular beats are diminished in number and strengthened in character, so that the heart performs its work with greater efficiency and clears up the results of impaired circulation, namely, dropsy. The diuretic action that takes place is not due to direct action on the kidney but on the circulation, thus improving the blood supply to the kidney. In auricular fibrillation, the slowing of the heart has been definitely proved to be due to the digitalis. In the condition of auricular flutter, treatment by digitalis converts it into fibrillation, and by withdrawal of the drug the normal rhythm of the heart is restored. In specific fevers and other conditions in which cardiac failure may ensue, it should be given early, so that the drug may be acting when the danger threatens. In ordinary conditions, it takes about twenty-four hours before its effect on heart muscle is appreciated. In urgent cases, strophanthus is often preferred because it acts very much more quickly, but digitalis often acts in six hours, or less, if 8 millilitres (2 fluid drachms) of tincture of digitalis is given to the patient, followed by 4 millilitres (1 fluid drachm) every four hours until the desired effect is obtained. Careful observation is, of course, required and the dose reduced after the therapeutic effect has been obtained, otherwise toxic symptoms may occur. Although digitalis constricts blood vessels slightly, it does not raise the blood pressure in these cardiac patients, and on broad principles such an increase of pressure is undesirable as entailing more work for the heart.

Digitalis is cumulative, and this is especially the case with digitoxin. The other digitalis glycosides are excreted more rapidly, excretion being complete in about a week. In the case of galenical preparations, it is found that about 25 per cent. is still present in the body after ten days. The active principles of digitalis are irritating to the gastric mucous

membrane and may cause nausea and vomiting. Evidence of accumulation is shown by headache, giddiness, sickness, and a marked slowing of the pulse.

Digitalis leaf is **administered** as Digitalis Pulverata in tablets or as Pilulæ Digitalis Compositæ, and also as Tinctura Digitalis or Infusum Digitalis Recens. The use of a concentrated infusion is not sanctioned. When digitalis by mouth is not tolerated, the tincture may be given as a rectal enema in doses up to 4 millilitres diluted to 100 millilitres with physiological sodium chloride solution. When Digitalis Folium, Digitalis, Digitalis Folia or Pulvis Digitalis is prescribed, Digitalis Pulverata must be dispensed. In cases of **poisoning** by digitalis, where there is a very slow and irregular pulse, the administration of atropine is generally all that is necessary. In the more severe cases, with very rapid heart-beat, the stomach pump must be used if the digitalis has been taken by the mouth, and drugs may be employed which depress and diminish the irritability of the heart, such as chloral and chloroform; amyl nitrite may also be found useful.

DIGITALIS LANATA.—Digitalis lanata consists of the leaves of *Digitalis lanata* Ehrhardt, a native to the neighbourhood of the Danube. The leaves are oblong-lanceolate, with an entire margin, which is ciliate in the basal half of the leaf; otherwise the leaf is glabrous. Digitalis lanata contains digitoxin, gitoxin and digoxin, $C_{41}H_{64}O_{14}$, a highly active, crystalline glycoside which has not been isolated from other species. Each of these glycosides also exists in the leaf in combination with dextrose and an acetyl group. These complex glycosides are described as digilanid A, B and C, respectively, and by enzymatic hydrolysis they can be converted into the simpler glycosides. Digilanid C is apparently identical with the glycoside, lanadigin, also obtained from *D. lanata*. In addition to the crystalline glycosides, the leaf contains amorphous glycosides. The leaf of *D. lanata* is usually three or four times more potent than the leaf of *D. purpurea*.

Preparations

Digitalis Pulverata, B.P.—(Digit. Pulverat.)—Powdered Digitalis. Digitalis leaf in No. 20 powder of ascertained strength, which is stated in units, one unit corresponding to the activity of 0.1 gramme of the international standard digitalis powder. Loss on drying at 100° , not more than 8 per cent. For therapeutic administration, the strength is adjusted to 10 units per gramme by admixture with exhausted digitalis leaf or with a weaker powdered digitalis. It should be stored in air-tight containers. Dose.—For a single administration, 0.2 to 0.6 gramme (3 to 10 grains), equivalent to 2 to 6 units of activity; for repeated administration, 0.03 to 0.1 gramme ($\frac{1}{2}$ to $1\frac{1}{2}$ grains), equivalent to 0.3 to 1 unit of activity.

Infusum Digitalis Recens, B.P.—(Inf. Digit. Rec.)—Fresh Infusion of Digitalis. *Syn.*—Infusum Digitalis, Infusion of Digitalis: It is prepared with the equivalent of 0.5 per cent. w/w of international standard digitalis powder. 120 millilitres or 4 fluid ounces contains 6 units of activity; it is one-twentieth the strength of tincture of digitalis. When Infusum Digitalis or infusion of digitalis is prescribed, fresh infusion of digitalis shall be dispensed. Dose.—6 to 20 millilitres ($1\frac{1}{2}$ to 5 fluid drachms); single dose.—30 to 120 millilitres (1 to 4 fluid ounces).

Pilulæ Digitalis Compositæ, B.P.C.—(Pil. Digit. Co.)—Compound Digitalis Pills. *Syn.*—Pilulæ Digitalis cum Scilla; Guy's Pills; Niemeyer's Pills. Each pill contains 1 grain each of powdered digitalis, squill, and pill of mercury. Dose.—1 or 2 pills.

Tinctura Digitalis, B.P.—(Tinct. Digit.)—Tincture of Digitalis. Each millilitre possesses one unit of activity and is equivalent to 0.1 gramme of the international standard digitalis powder. It may be prepared from digitalis leaf by percolation with alcohol (70 per cent.), the product being adjusted to the required strength, or it may be prepared from powdered digitalis by percolation without subsequent adjustment. 6 millilitres or $1\frac{1}{2}$ fluid drachms contains 6 units of activity. Dose.—0.3 to 1 millilitre (5 to 15 minims); single dose, 2 to 6 millilitres ($\frac{1}{2}$ to $1\frac{1}{2}$ fluid drachms).

Tinctura Digitalis I.A. is prepared with alcohol (70 per cent.) from 10 per cent. w/w of digitalis leaf. **Sirupus Digitalis I.A.** contains 5 per cent. of **Tinctura Digitalis I.A.**

DIGITOXINUM

(Digitox.)

Digitoxin

Synonym—Digitaline Crystallisée.

Digitoxin of commerce is obtained from digitalis leaf and consists mainly of a definite, crystalline glycoside, digitoxin, $C_{41}H_{64}O_{13}$, associated with other more soluble glycosides and usually a small proportion of a sparingly soluble glycoside, gitoxin, $C_{41}H_{64}O_{14}$. It occurs as a white, microcrystalline powder, or in colourless, rectangular plates. It has an intensely bitter taste. When a solution of 0.001 gramme of digitoxin in 1 millilitre of acetic acid containing a trace of ferric chloride is superimposed upon 1 millilitre of sulphuric acid, a brown band is formed; the upper part of the sulphuric acid layer becomes brown with a tinge of red, while the lower part of the acetic acid layer changes to an indigo-blue colour which is stable for some hours.

Almost **insoluble** in water; sparingly soluble in ether; readily soluble in alcohol and chloroform.

Standard.—Digitoxin does not melt below 240° . Loss on drying at 100° , not more than 1 per cent.

Action and Uses.—Digitoxin is the most powerful of the glycosides which have been extracted from digitalis leaf, but owing to slow excretion it is cumulative in its action; five days after an injection, 50 per cent. of the amount injected is still present and some remains after twenty days. Other objections to digitoxin are its excessive irritant properties and vasoconstrictor action. It may be **administered** as pills or granules, or hypodermically in solution (1 in 1000), using as a solvent a mixture of alcohol (90 per cent.), 6 parts, glycerin, 3 parts, and water, 1 part. It may be given rectally in doses of 0.0005 to 0.0008 gramme ($\frac{1}{2000}$ to $\frac{1}{1000}$ grain). Solutions for **injection** may be prepared by aseptic methods in an oily medium, the oil having previously been heated at 150° for one hour; or in a sterilised mixture of alcohol, glycerin and water. The solution should be protected from light. In cases of

poisoning by digitoxin, the antidotes described under *Digitalis Folium* should be employed

Dose.—0·0001 to 0·001 gramme ($\frac{1}{8000}$ to $\frac{1}{1000}$ grain).

DIGOXINUM.—Digoxin $C_{41}H_{64}O_{14}$, is a definite, crystalline glycoside, isolated from the leaves of *Digitalis lanata*. It melts and decomposes at about 265° . When dissolved in glacial acetic acid containing a trace of ferric chloride and treated with sulphuric acid, it forms a brown ring, and the supernatant acetic acid gradually assumes an indigo-blue colour. The specific rotation of a 1 per cent solution in pyridine is $+13\cdot3^{\circ}$ for the mercury green line. When tested on frogs, 1 milligram of digoxin is equal to 0·28 milligram of ouabain. It is almost insoluble in water, sparingly soluble in chloroform, ethyl acetate and acetone, and more soluble in dilute alcohol. It is used in the treatment of auricular fibrillation, when rapid effects are desired, and is usually given by the mouth, but may be given intravenously. **Dose.**—For repeated administration, 0·0005 gramme ($\frac{1}{2000}$ grain); for a single administration, 0·0012 to 0·0015 gramme ($\frac{1}{800}$ to $\frac{1}{600}$ grain).

GITOXINUM.—Gitoxin, $C_{41}H_{64}O_{14}$, is a definite, crystalline glycoside, isolated from the leaves of *Digitalis purpurea* or *D. lanata*. It melts and decomposes at 285° . When dissolved in glacial acetic acid containing a trace of ferric chloride and treated with sulphuric acid, it forms a brown ring; the upper part of the sulphuric acid layer becomes red and the acetic acid layer gradually assumes an indigo-blue colour. The specific rotation of a 1 per cent. solution in pyridine is $+3\cdot5^{\circ}$ for the mercury green line. It is almost insoluble in water, sparingly soluble in chloroform, ethyl acetate and acetone, and more soluble in dilute alcohol.

DULCAMARA

(Dulcamar.)

Bittersweet

Synonyms.—Woody Nightshade; Dulcamaræ Caulis.

Bittersweet consists of the dried stems and branches of *Solanum Dulcamara* Linn. (Fam. Solanaceæ), a climbing, perennial shrub common in England and growing freely in Europe, Northern Asia, North Africa and North America. The stems are collected in the autumn, after the fall of the leaf, when the plant is two or three years old, dried and cut into pieces about 5 millimetres to 2 centimetres in length.

The stem is sub-cylindrical and about 6 millimetres in diameter. The outer surface is greenish-brown in colour and glabrous; it is marked with alternate leaf-scars and shows longitudinal furrows and wrinkles. The outer layer can be easily removed, disclosing a greenish cortex. The wood is yellowish in colour and shows from one to three concentric rings; the white pith has a central hollow. The taste is at first bitter and then sweet. The odour of the drug is unpleasant when fresh, but slight when dry.

Bittersweet contains two acid saponins, dulcamaretic acid which is non-glycosidal, and dulcamaric acid which is glycosidal. The drug also contains about 1 per cent. of a glycosidal alkaloid, solaceine.

Action and Uses.—Dulcamara is now rarely used in medicine, but has been administered as an infusion (Infusum Dulcamaræ, 1 in 10; dose, 1 to 2 fluid ounces).

DUODENI MEMBRANUM

(Duoden. Memb.)

Duodenal Membrane*Synonyms*—Pulvis Duodenalis; Duodenal Powder.

Duodenal membrane is prepared by cleansing the upper portion of the fresh duodenum of the pig, *Sus scrofa* Linn., removing the duodenal membrane by scraping, scaling the membrane on glass plates at 70° to 80°, powdering the scales when dry, mixing the powder with one-fourth its weight of calcium phosphate, and passing the mixture through a No. 60 sieve. It occurs as a light, greyish-brown, hygroscopic powder, with a slight odour suggesting that of cooked meat, and a slightly saline taste. This preparation must be kept in well-corked or stoppered bottles, and it will then retain its properties for some time. Duodenal membrane contains secretin, enterokinase, erepsin, invertase, lactase and maltase.

Action and Uses.—The therapeutic action of duodenal membrane may be due to the large quantities of enterokinase contained in it, which converts the inactive trypsinogen of pancreatic juice into highly active trypsin. The other enzymes contained in the powder, erepsin, invertase, lactase and maltase, may assist the digestion of proteoses, sucrose, lactose and maltose contained in the food. It is useless as a pancreatic stimulant, since secretin is not absorbed from the lumen of the alimentary canal and is rapidly destroyed by both pepsin and trypsin.

Dose.—0.2 to 0.6 gramme (3 to 10 grains).

LIQUOR DUODENALIS.—Duodenal solution is a solution of the constituents of the duodenal membrane freed from proteins and containing the equivalent of 10 per cent. of the original mucous membrane. It remains active for twenty-four hours, after which time it quickly loses its activity. The deterioration may be retarded, however, for some weeks if the solution is kept slightly acid and sterile and stored in the dark. It is active when injected hypodermically, but useless when given by the mouth.

SECRETINUM.—Secretin is the specific hormone for the external secretion of the pancreas. It is found in the active form in the mucous membrane of the duodenum and jejunum of all vertebrates, and may be extracted from mucous membrane of pigs' duodena by alcohol, 5 per cent. sodium chloride, or 0.4 per cent. hydrochloric acid. It is soluble in water and alcohol. The solution in water gives some of the protein colour reactions, and the active principle is quickly destroyed by pepsin and trypsin. Secretin, when absorbed into the blood, stimulates the pancreas to secrete large quantities of pancreatic juice and also increases the bile flow to a small extent. In the live animal, the passage of secretin into the blood ensues upon the entrance of bile into the duodenum. Presumably, the bile salts, in their passage through the cells of the intestinal mucosa, carry the secretin contained in them into the blood and thereby to the pancreas. There is no evidence that secretin stimulates the pancreas to produce its internal secretion (insulin). When administered hypodermically, it produces a slow and moderate secretion of pancreatic juice. It is most effective when administered intravenously but is useless when taken by the mouth, since it is rapidly destroyed by both pepsin and trypsin. It may be administered as Liquor Duodenalis.

ELATERIUM**(Elatarium)****Elatarium**

Elatarium consists of the dried sediment which deposits in the juice of the almost ripe fruits of *Echallium Elaterium* A. Rich. (Fam. Cucurbitaceæ), a plant common in Southern Europe, particularly in Malta and in the countries bordering on the Mediterranean. It is cultivated in England.

The drug occurs in thin, opaque, flat or slightly curved, rectangular pieces about 2 to 2.5 centimetres in either direction, and 2 to 5 millimetres thick, pale green in colour when fresh, becoming greyish on keeping. The fracture is short and granular, exhibiting minute crystals. The odour is slight, and the taste bitter and acid.

Elatarium contains from 14 to 30 per cent. of elaterin in the Maltese drug, and from 20 to 27 per cent. in the English drug, about 5 to 12 per cent. of water, about 8 per cent. of inorganic matter, a small quantity of starch, fatty acids, a phytosterol and sugar.

Standard.—Elatarium contains not less than 20 per cent. of elaterin.

Assay.—Macerate about 1 gramme, in powder, accurately weighed, with 50 millilitres of chloroform for twenty-four hours, shaking frequently. Filter, evaporate 25 millilitres to dryness, treat the residue with 1 millilitre of ether, and pour the ether on to a small filter. Re-extract the residue four times and pour the ether through the filter, dissolving any residue on the filter in chloroform and evaporating off the chloroform before each successive extraction of the combined residues with the ether; dry and weigh the residue of elaterin.

Action and Uses.—Elatarium is a powerful hydragogue cathartic, and is usually administered in pills. It is liable to considerable variation in strength.

Dose.—0.006 to 0.03 gramme ($\frac{1}{10}$ to $\frac{1}{2}$ grain).

ELATERINUM.—Elaterin, or momordicin, $C_{28}H_{38}O_7$, is a mixture of two crystalline isomerides, α -elaterin (60 to 80 per cent.) and β -elaterin, obtained from elaterium by boiling with alcohol, precipitating with water, purifying the precipitate by washing with ether, and recrystallising from dehydrated alcohol. α -Elaterin is levorotatory and physiologically inert; β -elaterin is dextrorotatory and possesses a high physiological activity. Elaterin occurs in the form of odourless, minute, white scales or prismatic crystals, having a slightly acid, bitter taste. It is insoluble in water and glycerin, slightly soluble in alcohol, benzene and ether, soluble in chloroform, and in solutions of alkalis from which it is reprecipitated by excess of acid. Sulphuric acid colours elaterin yellow, gradually changing to scarlet. A few drops of sulphuric acid added to a solution of about 0.01 gramme in 5 grammes of melted phenol produces a crimson colour, rapidly changing to scarlet. Elaterin must be carefully distinguished from the drug elaterium, and should be used with great caution, since its action is frequently followed by prostration. It does not appear to be absorbed. It is used chiefly in cardiac or renal disease, accompanied by dropsy. Elaterin is usually prescribed as Pulvis Elaterini Compositus (elaterin, 1 part, lactose, 39 parts), which is best administered in a pill with hyoscyamus. Dose.—0.0015 to 0.006 gramme ($\frac{1}{40}$ to $\frac{1}{10}$ grain).

ELEMI

(Elemi)

Elemi*Synonym*—Manila Elemi.

Elemi is an oleoresin obtained from *Canarium luzonicum* Miq. (Fam. Burseraceæ), a tree growing in Manila. The exudation, although spontaneous, is increased by hacking the bark and is removed by scraping every few days.

When fresh, elemi occurs in the form of an opaque, soft, granular, pale yellow mass, with the consistency of honey, becoming firmer, darker and more transparent on keeping. It has a fragrant, balsamic odour recalling that of a mixture of mace and fennel. The taste is spicy and bitter. When examined **microscopically**, the oleoresin is seen to contain numerous acicular crystals.

Elemi **contains** a volatile oil, about 20 to 30 per cent., consisting chiefly of terpenes, crystalline and amorphous resin acids, bryoidin, and a bitter principle. The resinous constituents are α -manelemic acid (crystalline, melting-point, 215°), β -manelemic acid (amorphous), α - and β -manamyryn (both crystalline) and manelresene.

Substitutes.—East African elemi, from *Boswellia Frereana* Birdw., occurs in stalactitic masses and pale amber-yellow fragments. A variety from the Cameroons is derived from *Canarium Schaven-furthu* Engl. Brazilian elemi, from *Protium heptaphyllum* March., occurs in almost odourless, small, brown nodules. Yucatan elemi, from *Myrsin Plumeri* DC, forms hard, yellow, translucent pieces, curved on one side and having an aromatic odour; this variety is sometimes used in place of Canada balsam as a microscopical mounting medium.

Action and Uses.—Elemi is used as an ingredient of ointments when a mild stimulant is required. In this form it acts in the same way as resinous substances generally, giving protection to the skin. The ointment (Unguentum Elemi) usually contains 20 per cent. of elemi in simple ointment; an ointment is also prepared containing 10 per cent. in spermaceti ointment with the addition of 5 per cent. of balsam of Peru.

EMBELIA

(Embel.)

Embelia

Embelia consists of the dried fruits of *Embelia Ribes* Burm. f., and of *E. robusta* Roxb. (Fam. Myrsinaceæ), shrubs indigenous to India, the islands of the Indian Archipelago, and East Africa.

The fruits are spherical, about 4 millimetres in diameter, and vary in colour from red to nearly black. The fruits of *E. Ribes* are warty, those of *E. robusta* are finely striated longitudinally. In both kinds a short pedicel is often present, and a small five-partite calyx; when these are removed they leave a small hole in the fruit. The pericarp is brittle, and encloses a reddish seed which is covered with a

thin membrane; on removing this, the seed is seen to be covered with light spots, which become less distinct upon soaking in water. The seed is depressed at the base, and has a horny and slightly ruminated endosperm. The drug has a slightly astringent, aromatic taste. When 0.2 gramme of powdered embelia is shaken with 5 millilitres of ether and filtered, the filtrate, with one or two drops of dilute solution of ammonia, gives a bluish-violet precipitate.

Embelia contains about 2.5 per cent. of embelin or embelic acid, $C_{18}H_{28}O_4$, obtainable in golden-yellow, lamellar crystals, melting at 142° , insoluble in water, soluble in alcohol, ether, chloroform, and benzene. It also contains an alkaloid, christembine, together with resin and tannin.

Action and Uses.—Embelia is used in India and in the Eastern Colonies for the treatment of tape-worm, but is stated to possess little or no anthelmintic action. It is administered in milk on an empty stomach, and followed by a purgative.

Dose.—4 to 16 grammes (1 to 4 drachms).

EMETINA

(Emet.)

Emetine

Emetine, or methylcephaeline, is an alkaloid obtained from ipecacuanha. It occurs as an amorphous, white powder, having a bitter taste; it darkens on exposure to light, gradually assuming a yellow colour. It is strongly alkaline to litmus and forms crystalline salts with acids. Its insolubility in caustic alkalis distinguishes it from cephaeline. On the addition of sulphomolybdic acid to which 0.1 per cent. of sodium chloride has been added, a bright grass-green colour is produced. Melting-point, about 74° . Specific rotation in chloroform, about -50° ; in dissociated solvents the optical rotation may vary from -25° to -50° . It should be stored protected from light.

Slightly soluble in water; soluble in alcohol, ether, benzene, chloroform, fixed oils and hot light petroleum; insoluble in essential oils and solutions of caustic alkalis.

Standard.—Emetine loses, on drying in a vacuum at atmospheric temperature, not more than 1 per cent. of its weight. Ash, not more than 0.1 per cent. 0.2 gramme, dissolved in 1 millilitre of N/1 hydrochloric acid and 10 millilitres of water, complies with the limit test for cephaeline in Emetinæ Hydrochloridum.

Action and Uses.—Emetine has the action of emetine hydrochloride, in which form it is generally used, but a solution containing 0.06 gramme (1 grain) of the free base in 24 millilitres (6 fluid drachms) of olive oil has been administered as an enema in chronic amœbic dysentery.

Dose.—0.005 to 0.06 gramme ($\frac{1}{20}$ to 1 grain)

CEPHÆLINA.—Cephaeline, an alkaloid obtained from ipecacuanha, occurs as white, silky needles, becoming yellow on exposure to light. The base, crystallised from ether and air-dried, melts at about 115° to 116° . With sulphomolybdic acid it gives a purple colour, changing to prussian blue on the addition of hydrochloric acid. It is soluble in alcohol, chloroform, benzene and solutions of caustic alkalis, very sparingly soluble in light petroleum, and slightly soluble in ether (less so than emetine). Cephaeline is more toxic and a more powerful emetic than emetine. The action of cephaeline is slow and is obtained satisfactorily only by oral administration. Dose.—0.005 to 0.01 gramme ($\frac{1}{2}$ to $\frac{1}{4}$ grain).

EMETINÆ ET BISMUTHI IODIDUM

(Emet. et Bism. Iod.)

Emetine and Bismuth Iodide

Emetine and bismuth iodide is a complex iodide of bismuth and emetine, which may be prepared by precipitating an aqueous solution of emetine hydrochloride with excess of a solution made by dissolving bismuth carbonate and potassium iodide in hydrochloric acid. It occurs as an odourless, orange-red powder having a bitter, acrid taste. It is decomposed by alkalis with formation of emetine base, which may be extracted with chloroform; the separated alkaloid gives a green colour when moistened with sulphomolybdic acid and a trace of hydrochloric acid. It should be **stored** in well-closed containers protected from light.

Soluble in acetone; insoluble in water and alcohol (95 per cent.); slightly decomposed by, but insoluble in, dilute acids; soluble, with decomposition, in concentrated acids and in alkaline solutions.

Standard, B.P.—Emetine and bismuth iodide contains not less than 25 per cent. and not more than 28 per cent. of emetine, $C_{29}H_{40}O_4N_2$, and not less than 18 per cent. and not more than 21 per cent. of Bi. Loss on drying at 100° , not more than 2 per cent.

Action and Uses.—Emetine and bismuth iodide has the action of emetine hydrochloride. It was introduced in the belief that it would resist action by the acid of the stomach, and, after passing into the intestine, would remain in contact with encysted *Entamæba histolytica*. Unfortunately, administration by the mouth produces intense nausea, frequently with vomiting; hence pills and tablets should be enteric coated. The drug may also be administered by suspending it in a small quantity of liquid paraffin, which is then floated on two or three ounces of water. A course of emetine and bismuth iodide consists of 0.2 gramme (3 grains) daily for twelve days. The drug should be given on an empty stomach, last thing at night, and, if the patient has been found intolerant to it, 0.6 millilitre (10 minims) of tincture of opium should be given thirty minutes previously.

Dose.—0.06 to 0.2 gramme (1 to 3 grains).

EMETINÆ HYDROCHLORIDUM**(Emet. Hydrochlor.)****Emetine Hydrochloride**

Emetine hydrochloride is the hydrochloride of the alkaloid emetine, which may be obtained from ipecacuanha or by methylating cephaeline. It occurs as an odourless, colourless, crystalline powder, having a bitter taste and a neutral or faintly acid reaction. On exposure to light, it becomes faintly yellow. When mixed with a few drops of sulphomolybdic acid, a bright green colour is produced. Emetine hydrochloride should be **stored** in well-closed containers and protected from light.

Soluble in water and alcohol (90 per cent.).

Standard, B.P.—Emetine hydrochloride loses, on drying at 110°, not less than 15 per cent. and not more than 19 per cent. of its weight. Ash, not more than 0.1 per cent. It complies also with limit tests for readily carbonisable substances and for cephaeline.

Action and Uses.—Emetine hydrochloride has a markedly irritant action upon mucous membranes, and its administration by the mouth in doses of 0.006 gramme ($\frac{1}{160}$ grain) is followed by prompt emesis. Smaller doses have an expectorant action, but it is rarely administered for this purpose, since better results are obtained from powdered ipecacuanha, and the liquid extract and tincture of ipecacuanha. When it is administered parenterally, nausea and vomiting are less likely to occur. Emetine hydrochloride, and other salts of emetine, are specific in the treatment of amœbic dysentery. Hypodermic or intramuscular injections, concurrently with oral administration of emetine and bismuth iodide or emetine periodide, form the routine treatment in all cases of amœbic dysentery, and the initial injection should be made as soon as the diagnosis has been confirmed. The course consists, usually, of two injections daily of 0.03 gramme ($\frac{1}{2}$ grain), repeated until a total of about 0.6 gramme (10 grains) has been given, or until clinical symptoms have ceased and parasites have disappeared from the stools.

Encysted amœbæ, chiefly responsible for chronic amœbic dysentery, are more resistant to the action of emetine; hence it is necessary to prolong the treatment and to administer emetine hydrochloride, emetine and bismuth iodide, or acetarsol by the mouth. Owing to the slow elimination of emetine, not more than 0.75 gramme (12 grains) should be injected in one course, and if sigmoidoscopic and bacteriological observations remain positive, the injections should be stopped, and resumed after an interval of some weeks. Emetine has also been used in the treatment of chronic alcoholism. Large doses of emetine hydrochloride have been injected intramuscularly and intravenously in bilharziasis, but the initial dose for an adult should not exceed 0.03 gramme ($\frac{1}{2}$ grain). In the treatment of hepatic abscesses of amœbic origin, emetine hydrochloride should be administered intramuscularly

(1 grain in 1 to 2 fluid ounces of physiological saline solution), and also directly into the cavity after aspiration of the pus. Injections of emetine hydrochloride have also been found useful for arresting hæmoptysis. Solutions for **injection** may be sterilised by tyndallisation or by filtration, and the containers should comply with the tests for limit of alkalinity of glass. Capsules containing emetine hydrochloride should be treated with formaldehyde solution if intended for local treatment in the intestine, and pills and tablets should be enteric coated. The simultaneous administration of extract of ox bile will assist the disintegration of the salol if this has been used as the coating.

Dose.—0.03 to 0.06 gramme ($\frac{1}{2}$ to 1 grain), by injection.

EMETINÆ HYDROBROMIDUM.—Emetine hydrobromide, $C_{25}H_{46}O_4N_2 \cdot 2HBr \cdot 4H_2O$, occurs as a white, crystalline salt. It has the action and uses of emetine hydrochloride. It is less soluble than the hydrochloride, hence it is rarely administered, although solutions containing 0.03 gramme ($\frac{1}{2}$ grain) in 2.5 millilitres (40 minims) are occasionally given by intramuscular injection. **Dose.**—0.03 to 0.06 gramme ($\frac{1}{2}$ to 1 grain).

EMETINÆ PERIODIDUM.—Emetine periodide occurs as a dark purple, crystalline powder, containing about 40 per cent. of emetine, it is insoluble in water. It is administered in amœbic dysentery and, owing to the fact that it is not affected by the acid of the stomach, it does not cause nausea or vomiting. **Dose.**—0.12 gramme (2 grains).

EPHEDRA

(Ephed.)

Ephedra

Synonym—Ma-Huang.

Ephedra consists of the dried, young branches of the perennial herbs, *Ephedra sinica* Stapf and *E. equisetina* Bunge, indigenous to China, and of *E. Gerardiana* Wall. (including *E. nebrodensis* Tineo) (Fam. Ephedraceæ), indigenous to India.

The drug is imported in two forms, either compressed into bales, in which case it is much broken, and the pieces of green stem show depressions where contiguous pieces have overlain, or loosely packed, when it consists of entire branches or portions of branches, which are usually attached below to pieces of the older stems. The latter are woody, wrinkled longitudinally, and of a cinnamon-brown or ashen colour; from these, smaller branches of a similar colour arise, to which are attached the narrow, glaucous, green stems, up to about 30 centimetres long, which constitute the bulk of the drug. The green stems are sub-cylindrical and sometimes ancipital; they are longitudinally striated, and usually somewhat rough to the touch, although occasionally almost smooth. The internodes vary in length from 1 to 6 centimetres, and the opposite and decussate leaves are reduced to sheaths surrounding the stem, carrying diminutive subulate laminae, 1.5 to 4 millimetres long; occasionally the leaves occur in whorls of three. The

drug has a heavy, aromatic odour, recalling that of dried pine needles.

The diagnostic **microscopical** characters are the straight-walled, sub-rectangular, epidermal cells, with thickened outer walls, measuring about 22 to 35 microns in the radial and 9 to 25 microns in the tangential directions; the groups of 9 to 20 fibres in the ridges; the cortical parenchyma, which is about 4 to 7 cells thick, some of the cells containing small prisms of calcium oxalate; the presence of groups of 2 to 17 (usually 2 to 6) fibres in the cortex, and sometimes of a few fibres in the pith, either isolated or in groups of 2 or 3.

Ephedra **contains** *l*-ephedrine and its stereoisomeride *d-ψ*-ephedrine. The following closely related alkaloids are also present in small quantity: *l*-*N*-methylephedrine, *d*-*N*-methyl-*ψ*-ephedrine and nor-*d-ψ*-ephedrine. The total alkaloid present is about 1 to 2 per cent., of which about 70 per cent. is *l*-ephedrine.

Standard.—Ephedra contains not less than 1.25 per cent. of total alkaloids, calculated as $C_{10}H_{15}ON$.

Ephedra, in powder (*Pulvis Ephedræ*: *Pulv. Ephed.*), contains the constituents and possesses the diagnostic microscopical characters of Ephedra, and complies with the standard for the unground drug.

Assay.—Shake frequently during five minutes 20 grammes, in No. 40 powder, with 200 millilitres of a mixture of one volume of chloroform and 3 volumes of ether; add 10 millilitres of dilute solution of ammonia and 1 gramme of anhydrous sodium carbonate; shake at frequent intervals for four hours, and allow to stand overnight. Transfer to a percolator, and continue the percolation, first with 100 millilitres of the ether-chloroform mixture, and then with ether, until the alkaloid is completely extracted; shake the combined percolates with successive portions of 40, 30, 20, and 20 millilitres of *N*/3 hydrochloric acid; to the combined and filtered acid extracts, add *N*/1 sodium hydroxide until the liquid is only slightly acid, then add 10 grammes of anhydrous sodium carbonate and sufficient sodium chloride to saturate the liquid, and shake until dissolved. Extract the alkaline liquid with four successive portions of 60, 50, 50, and 30 millilitres of ether, and then with 25 millilitre portions of ether until the extraction of the alkaloid is complete (usually five shakings are sufficient). Allow the combined ether extracts to stand until clear, and decant through a filter into a beaker; warm, and pour off the ether from any crystals which may separate; evaporate the ether to a volume of about 10 millilitres, and then allow the residual solvent to evaporate spontaneously. Dissolve the residue in an excess of *N*/10 sulphuric acid, add 20 millilitres of water, and titrate the excess of acid with *N*/10 sodium hydroxide, using methyl red as indicator; each millilitre of *N*/10 sulphuric acid is equivalent to 0.01651 gramme of total alkaloids, calculated as $C_{10}H_{15}ON$.

Action and Uses.—The action of ephedra is due to the presence of ephedrine and pseudo-ephedrine (*d-ψ*-ephedrine). The two alkaloids

have a similar action on the respiratory tract, and are equally effective in asthma, but pseudo-ephedrine is said to be less liable to cause unpleasant effects, such as palpitation, tachycardia, fainting fits, constipation, and digestive disturbances. Pseudo-ephedrine is less powerful than ephedrine as a vasoconstrictor, but it stimulates the myocardium, whereas ephedrine depresses it. Ephedrine increases the coronary circulation. A combination of ephedrine and pseudo-ephedrine is superior to ephedrine alone for cardiac stimulation, in that due balance is maintained between vasoconstriction on the one hand, and myocardial stimulation with increased coronary circulation on the other. Ephedra may be **administered** as *Extractum Ephedræ Liquidum*. A tincture, said to contain the two alkaloids in approximately equal proportions, and adjusted to represent $\frac{1}{2}$ grain of total alkaloids in 60 minims, has been used in doses of 1·2 to 4 millilitres (20 to 60 minims) as a cardiac stimulant in the failing heart of epidemic dropsy, pneumonia, diphtheria, and septicæmia.

Preparation

Extractum Ephedræ Liquidum, B.P.C.—(Ext. Ephed. Liq.)—Liquid Extract of Ephedra. 1 in 1. Dose:— 1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

EPHEDRINA

(Ephed.)

Ephedrine

Ephedrine, $\text{C}_6\text{H}_5\cdot\text{CH}(\text{OH})\cdot\text{CH}(\text{NH}\cdot\text{CH}_3)\cdot\text{CH}_3$, is α -hydroxy- β -methylapinopropylbenzene, an alkaloid which may be isolated from *Ephedra sinica* Stapf, *E. equisetina* Bunge, or other species of *Ephedra*. It occurs in nearly colourless, crystalline masses. The base is very deliquescent, and rapidly absorbs moisture and carbon dioxide. It is dextrorotatory in aqueous solution and lævorotatory in alcoholic solution. It melts between 35° and 42°. When 0·01 gramme is dissolved in 1 millilitre of water, a violet colour develops after the addition of 0·1 millilitre of copper sulphate solution, followed by 1 millilitre of sodium hydroxide solution; the mixture, when shaken with ether, imparts a purple colour to the ether, and the aqueous solution becomes blue. A solution of 0·1 gramme in 20 millilitres of chloroform, after standing for twelve hours, yields, on allowing the chloroform to evaporate spontaneously, a white, crystalline residue of ephedrine hydrochloride, which melts between 214° and 220°. From the salts of ephedrine the base may be liberated by adding ammonia, and extracted by shaking with successive portions of ether; spontaneous evaporation of the ether gives a residue of the base which may be dried in a desiccator; when heated it volatilises.

Readily **soluble** in water, alcohol, glycerin (about 1 in 20), olive oil (about 1 in 25) and liquid paraffin (about 1 in 100).

Standard.—Ephedrine does not melt below 35° . Specific rotation, determined on a 2 per cent. w/v solution in carbon dioxide-free water, not less than $+12.5^{\circ}$. Ash, not more than 0.1 per cent. To 0.2 gramme in 5 millilitres of water add 0.5 millilitre of dilute nitric acid and 0.5 millilitre of silver nitrate solution; no precipitate is obtained (absence of chloride). To 0.2 gramme in 5 millilitres of water add 0.5 millilitre of dilute hydrochloric acid and 0.5 millilitre of barium chloride solution, and boil; no opalescence is produced within fifteen minutes (absence of sulphate).

Action and Uses.—The physiological effects of ephedrine are, in general, similar to those of adrenaline in moderate doses, and are due to stimulation of the myoneural junctions of the sympathetic nerve endings. Moderate doses, given either orally or hypodermically, raise the blood pressure, reinforce the action of the heart, contract the vascular system, stimulate the respiratory system, relieve bronchial spasm, contract the uterus, and dilate the pupil. Although it may stimulate the alimentary tract, it more frequently inhibits activity. Ephedrine is of low toxicity, but certain persons may display an idiosyncrasy towards the drug. The untoward symptoms that may occur are palpitation, trembling, nausea, weakness and sweating, and dermatitis. The prolonged administration of ephedrine does not appear to have any cumulative effect, and does not result in habit formation. It should be administered with caution when cardiac disorders are present, especially when there are signs of decompensation. In acute circulatory collapse, ephedrine is contra-indicated, since it may produce a further fall in blood pressure.

Ephedrine has been given largely in the treatment of asthma because of its effect in relieving bronchial spasm when administered orally. Relief is usually obtained in from twenty to thirty minutes, but this time can be reduced to from ten to fifteen minutes if ephedrine is given by subcutaneous or intramuscular injection. In hay fever, hypertrophic rhinitis and related affections, prompt relief is obtained by the local application of ephedrine solution, which constricts the nasal mucous membrane and reduces turgescence. Oral administration produces the same results, but they are less rapidly obtained and not so marked. In whooping cough, ephedrine relieves the spasmodic coughing, whooping and vomiting, although a slight cough remains. It does not influence the course of the infection. It is said to be most effective when given in conjunction with belladonna and expectorants. Ephedrine is of considerable value in checking the fall in blood pressure occurring in spinal anaesthesia; for this purpose it should be given as soon as the blood pressure shows signs of falling, since its effect is uncertain once the pressure has become low. In hyoscine and morphine anaesthesia it combats toxic symptoms without reducing the narcotic effect. In chronic hypotension due to infectious and other diseases, it

is less useful, its effect being only transitory. For routine examination with the ophthalmoscope, it forms a harmless and efficient mydriatic agent. Solutions of from 2 to 5 per cent. w/v act as a mydriatic, producing the maximum effect in from fifteen to thirty minutes. Accommodation is unaffected and, even when fully dilated, the pupil reacts to light. Mydriasis lasts from four to twelve hours.

Ephedrine has also been given to relieve the Adams-Stokes' syndrome, to relieve the nerve and joint pains in leprosy, and to relieve the pain of dysmenorrhœa. Since ephedrine contracts that portion of the bladder immediately behind the urethra, it is of value in the treatment of urinary incontinence, especially nocturnal enuresis in children. Ephedrine may be **administered** in solution, or dissolved in liquid paraffin in 1 per cent. w/v solution, and applied to the nose and throat to relieve congestion. For oral or hypodermic injection, the sulphate or hydrochloride is usually preferred.

Dose.—0.016 to 0.1 gramme ($\frac{1}{4}$ to $1\frac{1}{2}$ grains).

Preparations

Nebula Adrenalinæ et Ephedrinæ Oleosa, B.P.C.—(Neb. Adrenal. et Ephed. Oleos.)—Oily Adrenaline and Ephedrine Spray. Adrenaline, 1 in 10,000, and ephedrine, 1 in 50, with menthol and eucalyptol, in acidified dehydrated alcohol, castor oil and arachis oil.

Nebula Ephedrinæ Composita, B.P.C.—(Neb. Ephed. Co.)—Compound Ephedrine Spray. Ephedrine, 1 per cent. w/v, with menthol, camphor, oil of thyme and light liquid paraffin.

Unguentum Ephedrinæ, B.P.C.—(Ung. Ephed.)—Ephedrine Ointment. Ephedrine, 1 per cent., in white soft paraffin.

EPHEDRINÆ HYDROCHLORIDUM

(Ephed. Hydrochlor.)

Ephedrine Hydrochloride

Ephedrine hydrochloride, $\text{C}_6\text{H}_5\cdot\text{CH}(\text{OH})\cdot\text{CH}(\text{NH}\cdot\text{CH}_3)\text{CH}_3\cdot\text{HCl}$, occurs in colourless, odourless crystals or crystalline powder, having a neutral reaction. It gives the reaction with copper sulphate described under Ephedrina, and when a solution of the separated base in chloroform is evaporated or allowed to stand, ephedrine hydrochloride is produced.

Soluble in water (1 in 5), alcohol (about 1 in 5) and glycerin (1 in 60); insoluble in olive oil and liquid paraffin.

Standard, B.P.—Ephedrine hydrochloride has a melting-point of 217° to 220° . Specific rotation in 5 per cent. w/v aqueous solution, $-33'$ to $-36'$. Loss on drying at 100° , not more than 0.5 per cent. Ash, not more than 0.1 per cent. It complies also with a test for absence of sulphate.

Action and Uses.—Ephedrine hydrochloride has the general properties described under ephedrine, and is suitable for administration orally or by hypodermic injection. Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. It is one of the salts commonly employed for the exhibition of ephedrine in aqueous solution. For application to mucous membrane, aqueous solutions of from 1 to 5 per cent. are employed; the solution may be used as a nasal spray to reduce swelling of the turbinate bodies in hay-fever and allied affections. Owing to its more prolonged effect, it is sometimes used together with adrenaline in order to supplement the rapid but transient effect of that drug. Ephedrine hydrochloride may be **administered** orally in tablets, or as Elixir Ephedrinæ Hydrochloridi. It may be incorporated in a snuff or nasal ointment.

Dose.—0.016 to 0.1 gramme ($\frac{1}{4}$ to $1\frac{1}{2}$ grains).

Preparations

Elixir Ephedrinæ Hydrochloridi, B.P.C.—(Elix. Ephed. Hydrochlor.)—Elixir of Ephedrine Hydrochloride. Each fluid drachm contains $\frac{1}{4}$ grain of ephedrine hydrochloride with distilled water, glycerin, spirit of chloroform, tincture of lemon, alcohol (90 per cent.) and syrup, coloured with compound solution of tartrazine. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Nebula Adrenalinæ et Ephedrinæ, B.P.C.—(Neb. Adrenal. et Ephed.)—Adrenaline and Ephedrine Spray. Adrenaline, as solution of adrenalinic hydrochloride, 1 in 8000, ephedrine hydrochloride, about 1 in 45, and glycerin of phenol, in cinnamon water.

EPHEDRINÆ SULPHAS

(Ephed. Sulph.)

Ephedrine Sulphate

Ephedrine sulphate, $[\text{C}_6\text{H}_5 \cdot \text{CH}(\text{OH}) \cdot \text{CH}(\text{NH} \cdot \text{CH}_3) \cdot \text{CH}_2]_2, \text{H}_2\text{SO}_4$, is the sulphate of the alkaloid ephedrine. It occurs in white or colourless, odourless crystals, and the aqueous solution is neutral to litmus and to methyl red. The salt usually melts between 246° and 253° , but the melting-point may be as high as 258° . The separated base responds to the copper sulphate and chloroform tests for ephedrine described under Ephedrina. 0.1 gramme in 10 millilitres of water acidified with hydrochloric acid gives a precipitate with barium chloride solution.

Soluble in water (1 in 2), alcohol (1 in 60) and glycerin (1 in 60); insoluble in olive oil and liquid paraffin.

Standard.—Ephedrine sulphate has a specific rotation, determined in 10 per cent. w/v aqueous solution, of $-30'$ to $-31.6'$. Loss on drying at 100° , not more than 0.5 per cent. Ash, not more than 0.1 per cent. To 0.2 gramme in 5 millilitres of water add 0.5 millilitre of dilute nitric acid and 0.5 millilitre of silver nitrate solution; no precipitate is obtained (absence of chloride).

Action and Uses.—Ephedrine sulphate has properties similar to those of ephedrine hydrochloride, and is used for the same purposes. Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration.

Dose.—0·016 to 0·1 gramme ($\frac{1}{4}$ to $1\frac{1}{2}$ grains).

ERGOTA

(Ergot.)

Ergot

Synonym—*Secale cornutum* I.A.

Ergot is the sclerotium of the fungus, *Claviceps purpurea* Tulasne (Fam. Hypocreaceæ), developed in the ovary of the rye, *Secale cereale* Linn. (Fam. Gramineæ). The sclerotia are usually separated by sifting the rye after it has been threshed. Ergot is imported principally from Russia, Poland, Spain and Portugal. It should be thoroughly dried, and **stored** in the unground condition in a cool place.

Ergot occurs in dark blackish-violet grains about 1·5 to 4 centimetres long and from 2 to 7 millimetres thick, straight or somewhat curved, fusiform, usually indistinctly three or four-sided, each flattened face bearing a longitudinal furrow, frequently irregularly cracked; the sclerotia are brittle, and break with a short fracture, the transverse surface being white or pinkish-white, with three or four darker strands radiating from the centre.

The diagnostic **microscopical** characters are the narrow, purplish-brown, longitudinally arranged rows of rectangular cells from the outer layer; the colourless pseudo-parenchyma of the interior, consisting of small, unequal, rounded or slightly elongated cells, containing abundant fixed oil and protein, and having highly refractive, thick walls, which respond to the tests for chitin; the absence of starch, calcium oxalate crystals, spores and vascular tissues.

Ergot **contains** three alkaloids, ergotoxine, ergotinine and pseudo-ergotinine, of which ergotoxine alone has the typical pharmacological action of ergot. Ergotoxine occurs as an amorphous powder and can be crystallised from benzene, from which it separates in association with the solvent; it forms crystalline salts with acids and is converted into ergotinine by boiling with methyl alcohol. Ergotinine and pseudo-ergotinine are both crystalline, and closely resemble each other; they differ in solubility and in specific rotation, but both give rise to ergotoxine on boiling with acids. All three alkaloids are very sparingly soluble in water; they occur only in traces in aqueous extracts of ergot, but are present in acid aqueous-alcoholic extracts. Extracts of ergot contain a number of amines, of which trimethylamine, isoamylamine, putrescine, cadaverine, agmatine, histamine and tyramine have been identified. These are present in small amount, and

have little action when given orally. Histamine produces a powerful but transient contraction of the uterus when injected. Tyramine, when injected, has a weak action on the uterus, but raises the blood pressure. The amines are probably produced by the elimination of carbon dioxide from the corresponding amino-acids. Of the latter, histidine, tyrosine, aspartic acid, valine and leucine have been isolated from ergot. There is clinical evidence that ergot also contains a substance, not yet identified, which causes an almost immediate but not very prolonged contraction of the uterus. Betaine, choline, acetylcholine and ergothioneine, the betaine of thiolhistidine, also occur in ergot. Other constituents include guanosine (vernine), uracil, the colouring matters sclererythrin, which gives a characteristic absorption spectrum, ergochrysin and ergoflavin, lactic, succinic and aminosecalonic acids, the sugar, trehalose, mannitol, partly free and partly as the glycoside, clavicepsin, and a polysaccharide, mannan. Ergot contains from 15 to 30 per cent. of fixed oil, which yields on saponification about 1 per cent. of sterols, of which ergosterol and dihydroergosterol have been characterised. The presence of vitamin D has also been recorded. The drug yields from 2 to 5 per cent. of ash, of which potassium acid phosphate is the chief constituent. Ergotamine and ergotaminine are crystalline alkaloids, the occurrence of which in the official ergot is controversial. They can be isolated from ergots of grasses, such as *Festuca*. Ergotamine has the same pharmacological action as ergotoxine. It can be converted into ergotaminine by heating with alcohol, and the reverse change can be effected by boiling with acids. Ergotamine forms crystalline salts, and is closely related to ergotoxine. Ergotaminine, like ergotinine, has but little pharmacological activity.

Varieties.—Portuguese and Spanish ergots contain a higher proportion of active alkaloids than the Russian and Polish varieties and may be distinguished by their larger average size. Good Spanish ergot contains from 0.1 to 0.25 per cent. of total alkaloids; Russian ergot contains much less, sometimes not more than 0.02 per cent.

Standard, B.P.—Ergot contains not less than 0.05 per cent. of the total alkaloids of ergot, calculated as ergotoxine, and not more than 2 per cent. of foreign organic matter.

Ergot, in powder, contains the constituents and possesses the diagnostic microscopical characters of the unground drug, but if stored without immediate removal of the fat, the alkaloidal content rapidly diminishes. When powdered ergot is prescribed, the standardised powder, *Ergota Præparata*, must be used.

Action and Uses.—Ergot stimulates plain muscle, directly or indirectly, throughout the body. The peripheral arterioles undergo a prolonged constriction, which causes a considerable increase of blood pressure in man. The heart beats more vigorously, its systole is more complete and its output is considerably increased. The action of ergot on the uterus is similar to that on other plain muscle; it augments the contraction of the fibres, and increases the general tonus of the uterine

muscle. It therefore has an emmenagogue effect in the non-gravid condition, and an echolic effect on the gravid uterus. Ergot is employed, almost entirely, to excite uterine contractions. It is thus largely used to check uterine hæmorrhage, and is specially valuable in the third stage of labour. For all hæmorrhage other than uterine, it may do harm by raising blood pressure. This is especially the case in hæmorrhage from the cerebral and pulmonary vessels, because these vessels are so poorly provided with vasomotor nerves that not only is the pressure in them raised by ergot, but they are dilated by the systemic constriction.

Two types of epidemic ergotism, caused by the prolonged use of ergotised rye bread, have been described, but are rarely, if ever, found together. There is a gangrenous form, which is characterised by agonising pain in the extremities, followed by dry gangrene of the peripheral parts of the body (ergotoxine action); and a second or nervous type of epidemic which is much more rare, and is characterised by paroxysmal, epileptiform convulsions. Consumption of rye bread contaminated with ergot causes burning pains and gangrene of the limbs; smaller doses produce headache, depression, twitching of the limbs, and a staggering gait.

The action of ergot when given by mouth appears to depend mainly on ergotoxine and on an unknown principle, the latter being present in the liquid extracts of both the 1914 and 1932 Pharmacopœias. The liquid extract of the British Pharmacopœia, 1914, when taken by mouth in sufficiently large doses, produces, within a few minutes, powerful uterine contractions persisting for an hour or so; the liquid extract of the British Pharmacopœia, 1932, has the same action, and is of greater value when the more prolonged action of ergotoxine is required. Ergot is usually **administered** as *Ergota Præparata*, in capsules, or as extract, liquid extract, or ammoniated tincture. When ergot, *Pulvis Ergotæ*, or powdered ergot is prescribed, *Ergota Præparata* should be dispensed. The liquid extract loses its activity very rapidly, especially when diluted in mixtures; it should therefore be given undiluted, or in mixtures freshly prepared.

Injectio Ergotæ Hypodermica, of the British Pharmacopœia, 1914, contained 33 per cent. w/v of extract of ergot and 1 per cent. w/v of phenol, in recently boiled and cooled distilled water, and was administered in doses of 5 to 10 minims.

HISTAMINA. Histamine is 4- β -aminooctylglyoxaline, $C_8H_{13}N_2 \cdot CH_2 \cdot CH_2 \cdot NH_2$, and may be prepared from protein decomposition products. It produces a marked fall in blood pressure and increases the frequency of uterine contractions. It is administered by injection as the acid phosphate in doses containing the equivalent of 0.001 gramme of histamine. When injected subcutaneously, it causes an increase in the gastric secretion. This effect is utilised as a diagnostic test to differentiate pernicious from secondary anaemia. A preliminary series of analyses of the gastric contents is made by the fractional-meal method, followed at a later date by the histamine test if there is complete absence of hydrochloric acid. From 0.5 to 1 c.c. of a 1 in 1000 solution of histamine phosphate is injected subcutaneously before the test meal is administered. If further analyses still show no hydrochloric acid, achlorhydria is diagnosed. The 1 in 1000 solution is also used, by means of a

skin reaction, as a diagnostic test of certain diseases with decreased circulation, such as Raynaud's disease, arteriosclerosis, etc. A drop of the solution is placed on a small area of skin (on the wrist, ankles or knees), and is pricked into the epidermis with a needle, the excess of solution being wiped off. In normal patients a reddish-purple spot appears, followed by a wheal after not more than about two and a half minutes.

TYRAMINA.—Tyramine is *p*-hydroxyphenylethylamine, $C_6H_4(OH) \cdot CH_2 \cdot CH_2 \cdot NH_2$, a base occurring in ergot and its extracts, but usually prepared synthetically. It resembles adrenaline in its action, but the effect is weaker and more prolonged. It has no local hæmostatic action. Tyramine has been used in the treatment of shock and collapse, being administered by injection of the solution of a soluble salt, in doses of 0.02 to 0.04 gramme ($\frac{1}{2}$ to $\frac{1}{5}$ grain).

Preparations

Ergota Præparata, B.P.—(Ergot. Præp.)—Prepared Ergot. Defatted ergot, in moderately fine powder, adjusted by admixture with exhausted ergot, or ergot of ascertained strength, to contain 0.1 per cent. of the total alkaloids of ergot, calculated as ergotoxine (limits, 0.08 to 0.12); 1 gramme contains about 0.001 gramme, and 15 grains contains about $\frac{1}{10}$ grain, of total alkaloids. It should be stored in air-tight containers. Dose.—0.3 to 1 gramme (5 to 15 grains).

Extractum Ergotæ, B.P.C.—(Ext. Ergot.)—Extract of Ergot. A soft extract containing, when freshly prepared, 0.5 per cent. of total alkaloids, calculated as ergotoxine; 0.2 gramme contains about 0.001 gramme, and 3 grains contains about $\frac{1}{10}$ grain, of total alkaloids. Dose.—0.06 to 0.2 gramme (1 to 3 grains).

This extract replaces the less active extract of the British Pharmacopæia, 1914, which was prepared from ergot by maceration with water, followed by the addition of alcohol (90 per cent.), and subsequent evaporation.

Extractum secalis cornuti aquosum I.A. consists of the aqueous extract re-extracted with alcohol (60 per cent.).

Extractum Ergotæ Liquidum, B.P.—(Ext. Ergot. Liq.)—Liquid Extract of Ergot. It is prepared from defatted ergot with alcohol (50 per cent.) acidified with tartaric acid, concentration, if necessary, being effected under reduced pressure at a temperature not exceeding 40°, and is adjusted to contain, when fresh, 0.06 per cent. w/v of the total alkaloids of ergot, calculated as ergotoxine; 1.2 millilitres contains 0.0007 gramme and 20 minims contains about $\frac{1}{10}$ grain. It deteriorates rapidly on keeping and is not used when the alkaloid content has fallen below 0.04 per cent. w/v. It should be stored in small, completely filled bottles, in as cool a place as possible. Dose.—0.6 to 1.2 millilitres (10 to 20 minims).

Extractum secalis cornuti fluidum I.A. and Extractum secalis cornuti fluidum acidum I.A. are prepared from 100 per cent. w/w of ergot.

Infusum Ergotæ Recens, B.P.C.—(Inf. Ergot. Rec.)—Fresh Infusion of Ergot. 1 in 20. When infusion of ergot or Infusum Ergotæ is prescribed, Infusum Ergotæ Recens should be dispensed. Dose.—30 to 60 millilitres (1 to 2 fluid ounces).

This infusion was included in the British Pharmacopæia, 1914, under the name of Infusum Ergotæ.

Tinctura Ergotæ Ammoniata, B.P.C.—(Tinct. Ergot. Ammon.)—Ammoniated Tincture of Ergot. Ergot, 1 in 4, and dilute solution of ammonia, 1 in 10. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopæia, 1914.

ERGOTOXINA

(Ergotox.)

Ergotoxine

Ergotoxine is an alkaloid of feebly basic properties obtained from ergot. Its formula has not been definitely established. It occurs as a light, white, amorphous powder, which darkens and becomes brown on exposure to light and air. It can be crystallised from benzene, from which it separates in association with two molecules of the solvent. When dissolved in sulphuric acid solution, it gives the reactions with dimethylaminobenzaldehyde and ferric chloride described under Ergotoxinæ Æthanosulphonas.

Soluble in acetone, alcohol, chloroform and ethyl acetate; sparingly soluble in ether; almost insoluble in water; soluble in solution of sodium hydroxide, but insoluble in solution of sodium carbonate.

Standard.—Ergotoxine has a specific rotation, determined on a 2 per cent. w/v solution of the anhydrous substance in chloroform, of not less than -180° . Loss on drying in a vacuum at 90° , not more than 5 per cent. Ash, not more than 0.1 per cent. The dry substance blackens and decomposes with evolution of gas between 190° and 200° .

Action and Uses.—Ergotoxine, when administered over considerable periods of time, produces gangrene, due to destruction of the capillary vessels and consequent arrest of blood flow. A single dose of 1 or 2 milligrams will do this in the cock's comb, and the tips of the comb drop off. Ergotoxine has the characteristic property of paralysing the motor terminations of the sympathetic nerves, leaving inhibitor terminations unaffected, a property which is employed as the basis for the biological assay of ergot. When injected intravenously into the spinal animal, it causes a rise of blood pressure and contraction of unstriated muscle in general, particularly that of the uterus. Ergotoxine is employed in obstetrics to produce contraction of the uterus in the puerperium, and differs from pituitary extract in causing a maintained spasm, so that if given before delivery, the foetal circulation is interrupted and the child may die. It should be given, therefore, only after parturition. Following hypodermic injection, there is a latent period of twenty or thirty minutes, so that immediate cessation of hæmorrhage is not produced. The effect lasts for a long time, and if an initial dose given by injection is followed by oral doses two or three times a day during the puerperium, the contraction of the uterus will then be maintained and loss of blood avoided. Ergotoxine is also employed to control menorrhagia. Overdosage is indicated by headache, depression and vomiting. When given by mouth, ergotoxine is absorbed slowly. It is **administered** in the form of its salts, such as the phosphate or ethanesulphonate.

ERGOTAMINA.—Ergotamine is an alkaloid of feebly basic properties. It crystallises in white or colourless plates, which darken readily on exposure to light and air. On heating, it decomposes at 213° to 214° . A solution of the alkaloid in

chloroform is strongly laevorotatory. The colour reactions are the same as those described under ergotoxine. It is identical in pharmacological action with ergotoxine, but chemically it is a distinct alkaloid. It is insoluble in light petroleum, soluble in alcohol, acetone and chloroform, sparingly soluble in ether, soluble in sodium hydroxide solution, but insoluble in sodium carbonate solution.

ERGOTAMINÆ TARTRAS.—Ergotamine tartrate occurs in colourless, rhombic crystals, which contain solvent of crystallisation. On heating, it decomposes between 177° and 184°. It is sparingly soluble in water and alcohol.

ERGOTININA.—Ergotinine is an alkaloid of feebly basic properties. It occurs in colourless needles, which darken and become brown on exposure to light and air. The colour reactions are the same as those of ergotoxine. The solution in alcohol or chloroform is strongly dextrorotatory. It blackens and decomposes, with evolution of gas, at about 239°. Crystalline salts have so far not been described. Mayer's reagent produces a precipitate in an aqueous solution containing 1 in 1,000,000 of ergotinine. Ergotinine is insoluble in water, soluble in alcohol (about 1 in 300), ether (about 1 in 1000) and insoluble in sodium hydroxide solution.

ERGOTOXINÆ ÆTHANOSULPHONAS

(Ergotox. Æthanosulph.)

Ergotoxine Ethanesulphonate

Ergotoxine ethanesulphonate occurs in colourless, odourless, acicular crystals containing approximately 83·6 per cent. of the alkaloid ergotoxine, obtained from ergot. The aqueous solution has an acid reaction to litmus, and exhibits a blue fluorescence. When a 0·02 per cent. w/v aqueous solution is mixed with twice its volume of a 0·125 per cent. w/v solution of dimethylaminobenzaldehyde in sulphuric acid diluted with an equal volume of water, and the mixture exposed to light, a deep blue colour is produced slowly; when a 0·02 per cent. aqueous solution is mixed with twice its volume of a 0·125 per cent. w/v solution of dimethylaminobenzaldehyde in a 65 per cent. v/v solution of sulphuric acid containing a trace of ferric chloride, a blue colour of somewhat greater intensity is produced immediately. On the addition of one or two drops of sulphuric acid to a 0·1 per cent. w/v solution of ergotoxine ethanesulphonate in glacial acetic acid containing a trace of ferric chloride, a purplish-blue colour is produced. It should be **stored** in an atmosphere of nitrogen in sealed tubes, protected from light. Solutions are unstable, and should be stored in a cool place and protected from light.

Standard, B.P.—Ergotoxine ethanesulphonate has a specific rotation, determined on a 4 per cent. w/v solution of the anhydrous salt in a mixture of acetone (2 volumes) and water (1 volume), of +112° to +122°, and a specific rotation of the separated anhydrous base, determined on a 2 per cent. w/v chloroform solution, of not less than -180°. It contains, when anhydrous, acid equivalent to not less than 16 per cent. and not more than 16·7 per cent. of ethanesulphonic acid. Loss on drying in a vacuum at 90° to 100°, not more than 5 per cent. Ash, not more than 0·1 per cent. It complies also with limit tests for chloride and sulphate.

Action and Uses.—Ergotoxine ethanesulphonate has an action similar to that of ergotoxine, and is employed on account of its solubility and greater stability. A solution for **injection** may be sterilised by tyndallisation or by filtration, and the containers should comply with the tests for limit of alkalinity of glass. The solution should be **stored** protected from light in a cool place.

Dose.—0.0005 to 0.001 gramme ($\frac{1}{120}$ to $\frac{1}{60}$ grain), by subcutaneous or intramuscular injection.

ERGOTOXINÆ PHOSPHAS

(Ergotox. Phosph.)

Ergotoxine Phosphate

Ergotoxine phosphate may be prepared by adding dilute phosphoric acid to a solution of the base in alcohol and allowing the salt to crystallise. It forms white or colourless needles, which darken and become brown on exposure to light and air. It decomposes at about 188°. Shaken with cold water, a typical colloidal solution is formed which is strongly opalescent and froths readily; the addition of hydrochloric acid produces a thick jelly, but acetic acid leaves the solution liquid. The aqueous solution is acid to litmus.

Soluble in boiling alcohol (1 in 18); less soluble in cold alcohol; sparingly soluble in water.

Action and Uses.—Ergotoxine phosphate has an action similar to that of ergotoxine. It has been employed as a soluble form of ergotoxine, but is being largely replaced by the more stable ethanesulphonate. A solution for **injection** may be sterilised by tyndallisation or by filtration, and the containers should comply with the tests for limit of alkalinity of glass. The solution should be **stored** protected from light in a cool place.

Dose.—0.0005 to 0.001 gramme ($\frac{1}{120}$ to $\frac{1}{60}$ grain), by subcutaneous or intramuscular injection.

ERIODICTYON

(Eriodict.)

Eriodictyon

Synonym—Yerba Santa.

Eriodictyon consists of the dried leaves of *Eriodictyon glutinosum* Benth. (Fam. Hydrophyllaceæ), a low, evergreen shrub which grows abundantly on dry hills in California.

The leaves are oblong-lanceolate, 5 to 15 centimetres long, 1 to 3 centimetres broad; the margin is more or less incurved, irregularly serrate or crenate-dentate, the apex is acute, and the leaf narrows into

a short, broad petiole. The upper surface of the leaves is yellowish-green, smooth, and covered with a brownish resin; the lower surface is whitish to yellowish-white, reticulated and densely tomentose. The texture is brittle when dry, flexible when moist. The odour is somewhat aromatic, and the taste balsamic and sweetish. The drug usually consists of leaves in small fragments, admixed with a small proportion of stems.

The diagnostic **microscopical** characters are the numerous unicellular, thick-walled, filiform covering trichomes of the under surface, about 10 microns wide and 250 microns long; the straight-walled, polygonal cells of the epidermis, with a striated cuticle; the glandular trichomes with short, unicellular stalks and globular heads having two tiers of cells, showing 6 to 8 cells in the upper tier, arranged in a circle; the numerous cluster-crystals of calcium oxalate in certain cells of the mesophyll, which has a palisade varying in thickness from 2 to 6 cells.

Eriodictyon contains five bodies of a phenolic nature: eriodictyol, $C_{15}H_{12}O_6$; homeriodictyol, $C_{16}H_{14}O_6$; chrysoeriodictyol, $C_{16}H_{12}O_6$; xanthocriodictyol, $C_{18}H_{14}O_7$; eridonol, $C_{19}H_{18}O_7 \cdot H_2O$. It also contains triacontane, pentatriacontane, free formic, acetic, cerotic and other acids, glycerides of certain fatty acids, a phytosterol, a yellow volatile oil, much resinoid matter and some glucose.

Standard.—Eriodictyon contains not more than 5 per cent. of its stem and not more than 2 per cent. of other foreign organic matter.

Eriodictyon, in powder (*Pulvis Eriodictyonis*: *Pulv. Eriodict.*), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—Eriodictyon is used as a bitter tonic and as a stimulating expectorant. It has been given in asthma, phthisis, chronic bronchitis and chronic inflammation of the genito-urinary tract. The drug is best **administered** in the form of a liquid extract [1 in 1, prepared with alcohol (25 per cent.); dose, 15 minims]. It is used sometimes to reduce the bitterness of suspensions of quinine, the liquid extract being mixed with an aromatic syrup for this purpose.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

ERYTHRITYLIS TETRANITRAS DILUTUS

(Erythrityl. Tetranit. Dil.)

Diluted Erythrityl Tetranitrate

Synonyms—Erythrityl Tetranitrate (50 per cent.); Erythrol Tetranitrate (50 per cent.).

Diluted erythrityl tetranitrate is a mixture of approximately equal weights of erythrityl tetranitrate ($C_4H_6(NO_3)_4 = 302.1$) and lactose. Pure erythrityl tetranitrate is obtained by the nitration of erythritol, a tetrahydric alcohol obtained from various lichens such as *Rocella*

tinctoria, and occurs in hard, white, tasteless crystals, melting at about 61° . It is rapidly decomposed by heat or by exposure to sunlight, and is liable to explode on percussion; admixture with lactose renders it safe to handle. Diluted erythrityl tetranitrate is a white, odourless powder, having only the slightly sweetish taste of lactose. The lactose present is soluble in water, and the residue obtained on evaporating the solution responds to the tests for lactose. The erythrityl tetranitrate can be extracted with dehydrated alcohol; on evaporating the alcoholic solution, the erythrityl tetranitrate obtained melts at about 61° , and explodes on percussion. Diluted erythrityl tetranitrate should be stored in a cool place and protected from light.

Partially **soluble** in cold water and alcohol (90 per cent.).

Standard, B.P.—Diluted erythrityl tetranitrate contains not less than 47.5 per cent. and not more than 52.5 per cent. of $C_4H_6O_{12}N_4$.

Action and Uses.—Erythrityl tetranitrate lowers blood pressure by dilating the peripheral arterioles. Its action is mild and prolonged, owing to its relative insolubility. The maximum dilatation occurs in from two to three hours. It is employed when it is desirable to lower blood pressure for a considerable time, by directly dilating arterioles, and is used in angina pectoris, asthma, arteriosclerosis, nephritis, etc. Erythrityl tetranitrate is usually **administered** in the form of tablets, which should be chewed and not swallowed whole. The dose may be increased to 0.2 gramme (3 grains), or more, if necessary. When erythrityl tetranitrate is prescribed, diluted erythrityl tetranitrate must be dispensed, twice the prescribed amount being supplied.

Dose.—0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains), representing 0.015 to 0.06 gramme ($\frac{1}{4}$ to 1 grain) of pure erythrityl tetranitrate.

MANNITYLIS HEXANITRAS.—Mannityl hexanitrate, or mannitol hexanitrate, $C_6H_8(NO_3)_6$, occurs as a white, crystalline powder, but on account of its liability to explode, it is mixed usually with an inert substance such as lactose or chocolate. Its action resembles that of erythrityl tetranitrate as a vasodilator and, although it may not be as powerful, it is probably more prolonged. Dose.—0.015 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

Preparation

Tabellæ Sodii Nitritis Compositæ, B.P.C.—(Tab. Sod. Nitrit. Co.)—Compound Tablets of Sodium Nitrite. Each tablet contains $\frac{1}{2}$ grain of sodium nitrite, $\frac{1}{2}$ grain of diluted erythrityl tetranitrate and 1 grain of ammonium hippurate. Dose.—1 or 2 tablets.

EUCALYPTOL

(Eucalypt.)

Eucalyptol

Synonym—Cineole.

Eucalyptol is the anhydride of menthan-1:8-dial. It is obtained chiefly from oil of eucalyptus, but is found also in oil of cajuput and other

oils. It occurs as a colourless liquid with a characteristic, aromatic, camphoraceous odour and a pungent, cooling taste. Eucalyptol forms a characteristic addition product with bromine, hydrochloric acid, hydrobromic acid, or phosphoric acid. It should be **stored** in well-closed bottles in a cool place and protected from light.

Soluble in alcohol (70 per cent.) (1 in 2); miscible in all proportions with alcohol (90 per cent.), carbon disulphide and glacial acetic acid.

Standard, B.P.—Eucalyptol contains not less than 97·5 per cent. w/w of cineole, $C_{10}H_{18}O$. Specific gravity, 0·928 to 0·930. Optical rotation, -1° to $+1^{\circ}$. Refractive index at 20° , 1·456 to 1·460. Freezing-point, not below 0° .

Action and Uses.—Eucalyptol has the action and uses of oil of eucalyptus. It is less irritating to the mucous membrane than the oil; hence it should be used in preparations for internal administration and for inhalation. Oily spray solutions contain 1 part in from 16 to 30 parts of light liquid paraffin. Eucalyptol suspended in water (1 in 1000) with the aid of a small quantity of tincture of quillaia is sometimes used as a bladder-wash.

Dose.—0·06 to 0·2 millilitre (1 to 3 minims).

EUCALYPTOL CHLORINATUM.—Chlorinated eucalyptol may be prepared by treating eucalyptol with potassium chlorate and hydrochloric acid, as described under *Oleum Eucalypti Chlorinatum*. Chlorinated eucalyptol is used as a solvent for dichloramine.

Preparations

Nebula Eucalyptolis Composita, B.P.C.—(Neb. Eucalyp. Co.)—Compound Eucalyptol Spray. *Syn.*—Nebula Thymolis Composita. Eucalyptol, 8 per cent. v/v, with camphor, menthol and thymol in light liquid paraffin.

Pastilli Mentholis et Eucalyptolis, B.P.C.—(Pastill. Menthol. et Eucalyp.)—Menthol and Eucalyptol Pastilles. Each pastille contains $\frac{1}{10}$ gram of menthol and $\frac{1}{4}$ minim of eucalyptol.

EUCALYPTUS

(Eucalyp.)

Eucalyptus

Synonyms—Eucalypti Folium; Eucalyptus Leaf.

Eucalyptus consists of the dried leaves of the blue gum tree, *Eucalyptus globulus* Labill. (Fam. Myrtaceæ), a large tree indigenous to Tasmania and Eastern parts of Australia, and cultivated in Southern Europe. The fresh leaves are used only for the distillation of the volatile oil. The leaves are dimorphous; those from younger plants, which are sessile, ovate, and cordate at the base, are not used in the dried state for official purposes.

The leaves measure about 30 centimetres in length and 4 centimetres

in width; they are ensiform, acute, entire, coriaceous, brittle and punctate; both surfaces are pale green, with minute, brown, corky spots; the petiole is short, flattened and twisted; the lateral veins anastomose to form a continuous line near the margin and parallel to it. The odour is agreeable and aromatic, and the taste is aromatic, pungent and slightly bitter.

The diagnostic **microscopical** characters are the isobilateral mesophyll; a midrib, which shows in transverse section one large crescent-shaped meristele, surmounted by two smaller vascular strands lying side by side, the whole group being surrounded by sclerenchymatous fibres; on both surfaces, numerous stomata surrounded by straight-walled, polygonal cells, which have a thick cuticle; the palisade three to four cells deep on both sides; the mesophyll, which contains numerous large, sub-spherical, schizo-lysigenous oil glands, some of which have voided their contents through the epidermis and have become lined with a layer of periderm; prismatic and cluster-crystals of calcium oxalate.

Eucalyptus **contains** from 1 to 3 per cent. of volatile oil, together with tannin, a bitter principle, and resins. It yields to alcohol (60 per cent.) about 22 to 30 per cent. of extractive.

Standard.—Eucalyptus contains not more than 1 per cent. of fruits, and not more than 2 per cent. of stems or other foreign organic matter.

Eucalyptus, in powder (*Pulvis Eucalypti* : *Pulv. Eucalyp.*), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—Eucalyptus is used in the form of tincture in the treatment of asthma, phthisis and chronic bronchitis.

Preparation

Tinctura Eucalypti, B.P.C.—(*Tinct. Eucalyp.*)—Tincture of Eucalyptus. 1 in 5.

Dose.—1 to 8 millilitres ($\frac{1}{4}$ to 2 fluid drachms).

EUFLAVINA

(Euflavin.)

Euflavine

$C_{14}H_{14}N_3Cl = 259.6$

Synonyms—Neutral Acriflavine; Neutroflavin.

Euflavine is 2 : 8-diamino-10-methylacridinium chloride. It may be prepared from acriflavine by neutralisation and precipitation with sodium chloride. It occurs as an orange-red or brownish-red powder, which dissolves in water to give an orange solution. Dilute solutions exhibit a strongly-marked green fluorescence. An aqueous solution

(1 in 100) yields a bulky, yellow precipitate on the addition of a solution of sodium salicylate, or of potassium ferricyanide solution. A concentrated aqueous solution does not effervesce on the addition of sodium bicarbonate (distinction from acriflavine). A 0.1 per cent. aqueous solution does not form a precipitate with solution of formaldehyde (distinction from proflavine).

Soluble in water; more soluble in warm water (about 1 in 4); slightly soluble in alcohol; nearly insoluble in ether, chloroform, fixed oils and liquid paraffin.

Standard.—Euflavine contains not less than 93 per cent. of $C_{14}H_{14}N_3Cl$, calculated on the substance dried at 120° . Loss on drying at 120° , not more than 7 per cent. 1 gramme, moistened with sulphuric acid and gently ignited, the residue being again moistened with sulphuric acid and re-ignited, leaves not more than 0.04 gramme of residue. A 0.2 per cent. aqueous solution remains clear on standing in the dark for twenty-four hours.

Assay.—Dissolve about 2 grammes, accurately weighed, in 250 millilitres of water, and dilute with water to 750 millilitres. Adjust the reaction of the solution, at room temperature, by the addition of N/1 hydrochloric acid, until faintly acid to congo-red paper, and then add 5 grammes of sodium acetate. Add 50 millilitres of M/10 potassium ferricyanide, stirring during the addition, set aside for ten minutes, filter through a Buchner funnel, and wash the precipitate with three successive quantities of 50 millilitres of water. To the combined filtrate and washings add separately 10 millilitres of hydrochloric acid, 10 grammes of sodium chloride, 1 gramme of potassium iodide, and 3 grammes of zinc sulphate dissolved in 10 millilitres of water, mixing after each addition. Set aside for three minutes, and titrate the liberated iodine with N/10 sodium thiosulphate, using starch mucilage as indicator. When the titration is nearly complete, allow to stand for a further three minutes, and then complete the titration. Determine by means of a blank experiment the number of millilitres of N/10 sodium thiosulphate equivalent to 50 millilitres of M/10 potassium ferricyanide and calculate the volume of M/10 potassium ferricyanide required by the euflavine; each millilitre of M/10 potassium ferricyanide is equivalent to 0.07788 gramme of $C_{14}H_{14}N_3Cl$.

Action and Uses.—Euflavine has an antiseptic action similar to that of acriflavine, and is preferred on account of its less irritant action on mucous surfaces. It is administered orally in tablets containing $\frac{1}{2}$ grain, coated to prevent disintegration in the stomach; large doses of potassium citrate and dextrose are given simultaneously to minimise damage to the kidneys and liver. Carbasus Euflavinæ is used as an antiseptic dressing.

Preparation

Carbasus Euflavinæ, B.P.C.—(Carbas. Euflavin.)—Euflavine Gauze. It contains about 0.1 per cent. of euflavine.

EUGENOL

(Eugen.)

Eugenol

Eugenol, or 2-methoxy-4-allylphenol, may be obtained by shaking oil of clove with excess of a solution of sodium hydroxide, drawing off the resulting solution of sodium eugenate, and decomposing by means of dilute sulphuric acid. It occurs as a colourless or slightly yellow, optically inactive liquid, which boils at about 252° and has an odour of cloves and a pungent, spicy taste. A blue colour is produced on the addition of dilute ferric chloride solution to its alcoholic solution; on oxidation with potassium permanganate, it yields vanillin. It should be **stored** in well-stoppered bottles and protected from light.

Soluble in all proportions of alcohol, ether, chloroform, and glacial acetic acid.

Standard.—Eugenol has a specific gravity of 1.072 to 1.074. Refractive index at 20° , 1.541 to 1.542. It is entirely and readily soluble in dilute solution of sodium hydroxide. 1 millilitre dissolved in 3 millilitres of sodium hydroxide solution, produces a clear solution on the addition of 27 millilitres of water, which becomes turbid on exposure to air (limit of terpenes). On the addition of 1 drop of ferric chloride solution to 5 millilitres of the solution obtained by shaking 1 millilitre of eugenol with 20 millilitres of water and filtering, a transient, greyish-green, but not blue or violet, colour is produced (absence of phenol).

Action and Uses.—Eugenol has the action and uses of oil of clove. It is used in dentistry as an antiseptic obtundent and local analgesic. A mixture with zinc oxide is used in dentistry as a temporary filling.

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

ISOEUGENOL.—Isoeugenol, $\text{C}_{10}\text{H}_{12}\text{O}_2$, may be prepared from eugenol by heating with potassium hydroxide. It occurs as a colourless or pale yellow oil having a powerful carnation-clove odour, a specific gravity of about 1.089 and a boiling-point of 112° under 4 mm. pressure. It is used in perfumery and in the manufacture of vanillin.

EUONYMUS

(Euonym.)

Euonymus

Synonym—Wahoo Bark.

Euonymus consists of the dried root-bark of *Euonymus atropurpureus* Jacq. (Fam. Celastraceæ), a shrub common in the Eastern United States.

The root-bark occurs in small, quilled or curved pieces, light in weight, from 2 to 4 millimetres thick, up to about 7.5 centimetres long and 1.5 centimetres wide. The outer surface has a soft, spongy, light ash-grey cork, marked with darker lines and patches; the inner surface is longitudinally striated, smooth and grey when free from fragments of pale yellow or buff wood. The fracture is short, and if the two pieces are separated, delicate elastic threads, formed from the contents of the secretion cells, are seen connecting them. The smoothed transverse section of the moistened bark exhibits a narrow, buff or light brown cork, a whitish cortex and darker phloem. The odour is faint, but characteristic, and the taste bitter and acid.

The diagnostic **microscopical** characters are the thin-walled cells of the cork; the cluster-crystals of calcium oxalate, and small starch grains in the cells of the parenchyma; the elongated cells with brownish, amorphous contents, scattered throughout the cortex and phloem; the absence of prisms of calcium oxalate.

Euonymus contains a crystalline alcohol, euonymol, the sterols, euonysterol, homo-euonysterol and atropurpurool, furan- β -carboxylic acid, dulcitol, citrullol and a mixture of fatty acids. The bark yields to alcohol (45 per cent.), about 25 per cent. of extractive.

Substitutes.—The stem bark usually occurs in long, thin strips with a greenish-grey cork, green cortex and fibrous phloem. Wafer ash bark (*Ptelea trifoliata* Linn., Fam. Rutaceæ) differs from euonymus bark in being thicker, in bearing long, transverse, whitish scars, and in exhibiting, in transverse section, a layer of sclerenchyma within the cork and large oleo-resin cells in the phloem.

Standard.—*Euonymus* contains not more than 5 per cent. of adhering wood, and not more than 2 per cent. of other foreign organic matter. Acid-insoluble ash, not more than 4 per cent.

Euonymus, in powder (*Pulvis Euonymi* : *Pulv. Euonym.*), contains the constituents and possesses the diagnostic microscopical characters of *Euonymus*, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—*Euonymus* is a mild cathartic and is said to increase the flow of bile; since the drug is not absorbed, this cannot be due to a specific effect upon the liver, but is probably due to a reflex contraction of the gall bladder, an effect common to all purgatives which irritate the duodenum. It is **administered** in the form of extract, tincture, and as an elixir with *pulsatilla*. The extract is made into pills with syrup of liquid glucose, or combined with iridin or the extracts of *cascara sagrada*, *hyoscyamus*, or *nux vomica*; it is also prepared in tablet and capsule form, especially with *cascara sagrada*.

Preparations

Elixir Euonymi et Pulsatillæ, B.P.C.—(*Elix. Euonym. et Pulsat.*)—Elixir of *Euonymus* and *Pulsatilla*. Tincture of euonymus and tincture of *pulsatilla*, of each 1 in 8, with simple elixir. Dose—1 to 16 millilitres (1 to 4 fluid drachms).

Extractum Euonymi, B.P.C.—(Ext. Euonym.)—Extract of Euonymus. *Syn.*—Euonymin; Brown Euonymin. The alcoholic percolate evaporated to dryness, and mixed with one-fourth its weight of calcium phosphate. Dose.—0·06 to 0·12 gramme (1 to 2 grains).

This extract was included in the British Pharmacopæia, 1914.

Liquor Euonymini et Iridini, B.P.C.—(Liq. Euonym. et Iridin.)—Solution of Euonymin and Iridin. It contains the equivalent of about 3·5 per cent. w/v of extract of euonymus and about 2 per cent. w/v of extract of iris, with potassium carbonate, distilled water and alcohol (45 per cent.). Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Liquor Euonymini et Pepsini, B.P.C.—(Liq. Euonym. et Pepsin.)—Solution of Euonymin and Pepsin. Each fluid drachm contains 1 grain of extract of euonymus and 2 grains of pepsin, with hydrochloric acid, alcohol (45 per cent.) and chloroform water. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tinctura Euonymi, B.P.C.—(Tinct. Euonym.)—Tincture of Euonymus. 1 in 5. Dose.—0·6 to 2·6 millilitres (10 to 40 minims).

EUPHORBIA

(Euphorb.)

Euphorbia

Synonyms—Euphorbia Herb; Euphorbia Pilulifera.

Euphorbia is the dried, entire plant, *Euphorbia hirta* Linn. (Fam. Euphorbiaceæ), an annual herb indigenous to the hotter parts of India, and growing in most tropical countries. The plant is collected while flowering and fruiting.

The root is a conical tap-root about 5 millimetres in its greatest diameter, and bearing about four vertical rows of fibrous rootlets. The stem is slender and terete, and covered with coarse, bristly hairs of two kinds; it bears opposite, dark green leaves from 2 to 4 centimetres long, ovate or obliquely lanceolate in shape, with a dentate margin. Both surfaces are hairy, and the upper surface is rugose. They are brittle and usually much broken in the drug, and when held to the light they show pellucid spots. The flowers are small, numerous, and crowded together in dense cymes about 1 centimetre in diameter. The fruit is a yellow, three-celled, keeled capsule about 1 to 2 millimetres in diameter, containing three reddish-brown, four-sided, angular, wrinkled seeds. The drug has a bitter taste.

Euphorbia **contains** amongst the water-soluble constituents, gallic acid, quercetin, a phenolic substance, an amorphous glycoside and a sugar. The portion soluble in alcohol, but insoluble in water, contains triacontane, a monohydric alcohol, euphosterol, a phytosterol and phytosterolin, jambulol, melissic acid and a mixture of fatty acids

Standard.—Euphorbia contains not more than 5 per cent. of foreign organic matter. Acid-insoluble ash, not more than 3 per cent.

Euphorbia, in powder (Pulvis Euphorbiæ : Pulv. Euphorb.), contains the constituents and possesses the diagnostic microscopical characters

of Euphorbia, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Euphorbia has a depressant action upon the heart and respiration, and causes relaxation of bronchi by central action. It is **administered** in the form of liquid extract or tincture (Tinctura Euphorbiæ, 1 in 5; dose, 10 to 30 minims) with lobelia or senega, in asthmatic conditions, chronic bronchitis, emphysema, coryza and hay fever.

EUPHORBIA PEPLUS.—Petty spurge, or devil's milk, is the entire plant, *Euphorbia Peplus* Linn., which is indigenous to the British Isles. It is a slender annual with a procumbent, sometimes erect, stem, having minute stipules to the leaves on the floral axes, and involucre bracts with very long cusps. A tincture and a liquid extract have been recommended in asthma and bronchial catarrh.

Preparation

Extractum Euphorbiæ Liquidum, B.P.C.—(Ext. Euphorb. Liq.)—Liquid Extract of Euphorbia. *Syn.*—Extractum Euphorbiæ Piluliferæ Liquidum. 1 in 1. Dose. 0·12 to 0·3 millilitre (2 to 5 minims).

EUPHORBIIUM

(Euphorbium)

Euphorbium

Euphorbium is the dried latex obtained by incision from the stem of *Euphorbia resinifera* Berg. (Fam. Euphorbiaceæ). The plant is common in the mountainous districts of Morocco.

The dried latex occurs in dull, yellowish-brown tears, or small irregular masses, up to about 1·5 centimetres wide, many of which are perforated owing to the solidification of the latex around a pair of stipules; in some cases the stipules are still embedded in the masses, as also are portions of the fruits and inflorescences. Admixed with the drug may be found fragments of the stem with stipules attached, the tri-locular fruits, consisting of three almost equal, one-celled, keeled carpels, attached to a central axis, and a few of the typical cyathia. It is very brittle, almost odourless, has an acrid taste, and the powder is strongly sternutatory. Euphorbium may be identified by the following test:—Shake 4 millilitres of light petroleum with 3 grammes of a mixture of powdered euphorbium with twice its weight of sand, filter, and pour a little of the filtrate on the surface of 2 millilitres of a mixture of 1 volume of nitric acid and 400 volumes of strong sulphuric acid; a blood-red ring is formed at the junction of the liquids.

Euphorbium **contains** euphorbone, a colourless, crystalline principle melting at 115° to 116° (about 40 per cent.), euphorbo-resene, a yellowish-brown, amorphous substance (about 20 per cent.), euphorbic acid, calcium malate (about 25 per cent.), and an acrid principle, soluble in water, alcohol and ether, to which the physiological action is due.

Euphorbium yields to alcohol (90 per cent.) about 50 per cent. of extractive.

Standard.—Euphorbium yields not more than 10 per cent. of ash.

Action and Uses.—Euphorbium is emetic and powerfully cathartic. On account of its violent action it is not used internally. Acute nephritis may follow the introduction of the drug into the system. Powdered euphorbium is a powerful irritant to the nasal mucous membrane, causing violent sneezing. Externally, it acts as a vesicant and as such is used in veterinary practice.

EXTRACTUM HEPATIS SICCU

(Ext. Hepat. Sicc.)

Dry Extract of Liver

Synonym—Extract of Liver.

Dry extract of liver is a selected fraction of an alcoholic extract of ox or sheep's liver, and contains the specific principle which increases the number of red corpuscles in the blood of persons suffering from pernicious anæmia. The livers are trimmed, minced, and macerated with frequent stirring in slightly acidified alcohol (80 per cent.) for twelve to eighteen hours. The filtered liquid is reserved, and the residue macerated as before, using alcohol (50 per cent.). The two filtrates are mixed, evaporated to a small bulk under reduced pressure, mixed with alcohol and clarified. The resulting liquid extract is evaporated under reduced pressure to a syrupy consistence, and the residual water removed by repeated treatment with dehydrated alcohol. The brittle product is dried, powdered, dried again *in vacuo* and mixed with sodium chloride. Dry extract of liver occurs as a light, brown, very hygroscopic powder with a meat-like odour and salty, meat-like taste. Nothing definite is known about the nature of the active constituents present in liver extract; usually vitamins B₁ and B₂ are present, together with a heat-stable substance which is elaborated in the stomach and stored in the liver, and is capable of causing an increase in the number of red cells in the blood of patients suffering from pernicious anæmia. There is no satisfactory method of assay other than actual clinical test. It should be **stored** in hermetically sealed glass tubes in a cool place.

Soluble in water; insoluble in alcohol (90 per cent.).

Standard, B.P.—Dry extract of liver contains not less than one-tenth its weight of sodium chloride, and is packed in tubes, each tube containing the equivalent of 225 grammes of the original liver.

Action and Uses.—Liver extract is used as a substitute for raw liver in the treatment of pernicious anæmia. Its mode of action is not definitely known, but it causes a marked rise in the number of reticulated red blood cells, followed by an increase in the total red cell

count, which can in most cases be brought to the normal figure of 5,000,000 per cubic millimetre. Dosage should be controlled by reference to the red blood cell count. Some improvement is also noticeable in the nervous symptoms due to peripheral neuritis, but in subacute combined degeneration of the spinal cord there is no regeneration of the damaged tissues. In secondary anæmia, treatment with liver extract is less satisfactory, but when it is given in conjunction with large doses of iron salts considerable improvement may result. Symptomatic improvement in disseminated sclerosis is said to have followed the administration of large doses of liver. In sprue associated with anæmia and a high colour index, liver extract has given good results and produced undoubted clinical cures. It is useful also in other so-called macrocytic hyperchromic anæmias, such as the pernicious anæmia of pregnancy and anæmias due to the presence of tape-worms and hook-worms.

The toxic effects produced by certain heavy metals are counteracted by liver extract; thus it has been administered for the dermatitis following the injection of arsenic and bismuth preparations. Early cases of manganese poisoning are said to have responded satisfactorily to liver therapy, and intramuscular injections of liver extract are used to prevent nausea and vomiting in patients undergoing X-ray treatment. Extractum Hepatis Siccum and Extractum Hepatis Liquidum are suitable preparations of liver for oral administration. Fractional extracts of liver suitable for intramuscular or intravenous injection have been obtained, and the use of such preparations has been followed by a rapid and marked increase in the number of red cells in the circulation. Liver extract given by injection produces the desired response with smaller doses administered at longer intervals.

Dose.—The quantity equivalent to 225 grammes (about half a pound) of fresh liver.

EXTRACTUM HEPATIS LIQUIDUM, B.P.—(Ext. Hepat. Liq.)—Liquid Extract of Liver. It is prepared by the method described for the dry extract, the solid precipitated by dehydrated alcohol being mixed with distilled water, glycerin and alcohol (95 per cent.). 30 millilitres is equivalent to 240 grammes of fresh liver, or 1 fluid ounce to 8 ounces of fresh liver; it contains also not less than 10 per cent. v/v of alcohol (95 per cent.) and 20 per cent. v/v of glycerin. It should be stored in well-closed containers in a cool place, but since it may lose activity on keeping it should be used as soon as possible after preparation. The label should state the weight of fresh liver equivalent to 30 millilitres or to 1 fluid ounce. Dose.—30 millilitres (1 fluid ounce).

EXTRACTUM MALTI

(Ext. Malt.)

Extract of Malt

Extract of malt is obtained from sound, malted grain of barley, *Hordeum distichon* Linn. (Fam. Gramineæ). It may be prepared by

macerating coarsely powdered malt with an equal weight of water for six hours, after which the marc is mixed with four times the original weight of water heated to about 30°, and the mass is allowed to digest for an hour at a temperature not exceeding 55°. It is then strained and pressed and the mixed liquids rapidly evaporated under reduced pressure, at a temperature not exceeding 55°, until a viscous product is obtained. Extract of malt occurs as an amber-coloured or yellowish-brown, viscous liquid with an agreeable, characteristic odour and a sweet taste. It **contains** maltose (50 per cent. or more) and dextrin, with dextrose, small proportions of other carbohydrates and diastase. Extract of malt should be **stored** in well-closed vessels in a cool place.

Standard, B.P.—Extract of malt contains nitrogen equivalent to not less than 4.5 per cent. by weight of protein. Specific gravity, 1.40 to 1.42. Refractive index at 20°, 1.4892 to 1.4976. Arsenic limit, 1.4 parts per million. It is miscible in all proportions with water, forming a translucent solution.

Action and Uses.—Extract of malt has nutritive and laxative properties. Its nutritive action depends upon the presence of carbohydrates and of the complex, water-soluble vitamin B. Extract of malt is known to be a good source of the antineuritic factor B₁. It is unlikely that diastase, a normal, but exceedingly variable, constituent of extract of malt, exerts any appreciable action during the digestion of food; the amount ingested is small compared with that of the starch-hydrolysing enzymes already present in the gut (see Diastasum). Extract of malt is digested easily, and may be **administered** undiluted to children, or a preparation of malt extract with cod-liver oil, halibut-liver oil, solution of irradiated ergosterol, or solution of vitamin A may be given. Malt extract is a useful vehicle for the administration of extract of cascara sagrada and salts of iron

Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Preparations

Extractum Malti cum Oleo Morrhuae, B.P.—(Ext. Malt. c. Ol. Morrh.)—Extract of Malt with Cod-liver Oil. Cod-liver oil, 10 per cent. w/w, in extract of malt. It contains approximately 15 per cent. v/v of cod-liver oil; 16 millilitres contains about 2.5 millilitres, and 4 fluid drachms contains about 36 minims. **Dose.** 4 to 16 millilitres (1 to 4 fluid drachms).

This extract was included in the British Pharmaceutical Codex, 1923.

Extractum Malti cum Oleo Olivæ, B.P.C.—(Ext. Malt. c. Ol. Oliv.)—Extract of Malt with Olive Oil. Olive oil, approximately 15 per cent. v/v, in extract of malt. **Dose.**—4 to 8 millilitres (1 to 2 fluid drachms).

Extractum Malti Ferratum, B.P.C.—(Ext. Malt. Ferrat.)—Ferrated Extract of Malt. It contains 1.5 per cent. of soluble iron pyrophosphate. **Dose.**—4 to 16 millilitres (1 to 4 fluid drachms).

Extractum Malti Liquidum, B.P.C.—(Ext. Malt. Liq.)—Liquid Extract of Malt. **Dose.**—4 to 16 millilitres (1 to 4 fluid drachms).

Extractum Malti Liquidum cum Glycerophosphatibus, B.P.C.—(Ext. Malt. Liq. c. Glycerophosph.)—Liquid Extract of Malt with Glycerophosphates. 4 fluid drachms contains the equivalent of 2 grains of potassium glycerophosphate and 2 grains of sodium glycerophosphate. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Extractum Malti Liquidum cum Hæmoglobino, B.P.C.—(Ext. Malt. Liq. c. Hæmoglob.)—Liquid Extract of Malt with Hæmoglobin. *Syn.*—Malt and Hæmoglobin. Hæmoglobin, 1 in 8, in glycerin and liquid extract of malt. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Extractum Malti Liquidum cum Hypophosphitibus, B.P.C.—(Ext. Malt. Liq. c. Hypophosph.)—Liquid Extract of Malt with Hypophosphites. 4 fluid drachms contains 1 grain of sodium hypophosphite and 1 grain of calcium hypophosphite in liquid extract of malt. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Extractum Malti Liquidum cum Quinina et Strychnina, B.P.C.—(Ext. Malt. Liq. c. Quinin. et Strych.)—Liquid Extract of Malt with Quinine and Strychnine. 4 fluid drachms contains about $\frac{1}{2}$ grain of quinine hydrochloride and $\frac{1}{16}$ grain of strychnine hydrochloride. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Extractum Malti cum Vitaminis, B.P.C.—(Ext. Malt. c. Vitamin.)—Extract of Malt with Vitamins. Solution of vitamin A, 1.0 per cent. w/w, and solution of irradiated ergosterol, 1.5 per cent. w/w, in extract of malt. It is about 3 times as potent as extract of malt and cod-liver oil; 4 millilitres (1 fluid drachm) contains about 3000 units of vitamin A and 225 units of antirachitic activity (vitamin D). Dose.—8 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

Extractum Malti Liquidum et Medullæ Rubræ, B.P.C.—(Ext. Malt. Liq. et Medull. Rub.)—Liquid Extract of Malt and Red Bone Marrow. Liquid extract of malt and extract of red bone marrow, equal parts. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Mistura Ferri cum Malto, B.P.C.—(Mist. Ferr. c. Malt.)—Mixture of Iron with Malt. Each fluid drachm contains 3 grains of soluble iron pyrophosphate with distilled water and liquid extract of malt. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

EXTRACTUM PARATHYROIDEI

(Ext. Parathyroid.)

Parathyroid Extract

Parathyroid extract is an extract prepared from the parathyroid glands, which are situated either alongside or inside the thyroid gland. The glands are dissected free from fat and connective tissue, and frozen until required; they are then immersed in 5 per cent. hydrochloric acid, and the containing vessel is placed in a bath of boiling water. After heating for a few minutes the glands are broken up under the acid, the heating is continued for an hour, and the fat, which separates as a surface layer, is removed. The extract is cooled, and sodium hydroxide is added to bring the reaction to pH 8.0. Hydrochloric acid is then added slowly until a maximum precipitation of protein occurs. The precipitate is separated, redissolved in alkali, reprecipitated by hydrochloric acid, and again separated. The combined liquids form an aqueous extract of the active principle, which can be sterilised by heating. Parathyroid extract is identified by its

power to raise the amount of calcium in the blood of dogs, when injected under the skin.

Standard.—There is no standard for parathyroid extract, and the unit is based on an animal reaction. The methods in common use are based on the rise in blood-calcium produced by injecting the extract into normal dogs, or dogs from which the parathyroid glands have been removed. One unit adopted is defined as one-hundredth part of the amount necessary to raise the blood-calcium of a dog weighing 20 kilograms by 5 milligrams per 100 millilitres.

Action and Uses.—Parathyroid extract raises the amount of calcium in the circulating blood by causing a withdrawal of calcium from the bones. This was discovered from the observation that *osteitis fibrosa*, a disease in which the bones become weak and break because of lack of calcium, is due to a parathyroid tumour from which excessive amounts of parathyroid hormone are secreted in the blood. Parathyroid extract is used to relieve the symptoms of any forms of tetany associated with the lowering of the calcium content of the blood. This may occur after the unavoidable removal of the parathyroids during operations on the thyroid. It is **administered** by hypodermic injection, and the doses are controlled by determinations of the calcium content of the blood, since hypercalcaemia may result from excessive dosage.

Dose.—20 to 40 units.

EXTRACTUM PITUITARII LIQUIDUM

(Ext. Pituit. Liq.)

Pituitary (Posterior Lobe) Extract

Synonyms—Liquor Pituitarii; Solution of Pituitary; Pituitary Extract.

Pituitary (posterior lobe) extract is the complete aqueous extract of the pituitary posterior lobes of freshly-killed oxen, sheep or pigs. The activity present in the lobes rapidly disappears unless the autolytic processes are checked by freezing the tissue. When the lobes are frozen, the active principles are stable; they are also stable in the powdered tissue after dehydration and removal of fat by acetone. The extract is prepared with 0.25 per cent. acetic acid, assayed and adjusted to the required strength and to pH 3, at which reaction it can be sterilised by heat without loss of activity. Tests for identity and purity are described in the British Pharmacopœia. The containers are required to comply with the conditions laid down, and the label must state the number of units per millilitre and the date of manufacture. Pituitary (posterior lobe) extract should not be used when more than eighteen months old; its rate of deterioration is least when the reaction is pH 3.

Standard, B.P.—Pituitary (posterior lobe) extract contains 10 units per millilitre. It complies with biological tests for activity and

sterility, and is assayed biologically by comparing its action on the uterus of a guinea-pig, under stated conditions, with that of a standard preparation which, for Great Britain and Northern Ireland, is kept in the National Institute for Medical Research, London. The potency is expressed in units which have been adopted by international agreement. The unit is defined as the amount of activity present in 0.5 milligram of the standard. Pituitary (posterior lobe) extract, and other aqueous solutions of one or more of the separated active principles of the posterior lobe, are controlled by regulations made under the Therapeutic Substances Act, 1925.

Action and Uses.—The pharmacological action of pituitary (posterior lobe) extract is not yet fully understood. It was formerly believed to be a stimulant of all unstriated muscle (muscle like that of the intestines, not under voluntary control), but it is now known that its action is, in the main, limited to the muscle of certain organs, and in particular that of the uterus and the arterial blood vessels. It has very little direct stimulant action on intestinal muscle, and its effect in paralytic ileus may be secondary to an increased outflow of bile. Pituitary (posterior lobe) extract, when injected, promotes the flow of milk from the mammary gland by its action on the plain muscle. There is, however, no increased secretion of milk. In the parturient uterus, moderate doses of pituitary (posterior lobe) extract increase the rate and force of the natural contractions, which are intermittent; the alternation of contraction and relaxation is not interrupted, as it is by the injection of ergotoxine. By its action on the walls of the arteries, an action which is exerted not only on the large but also on the small vessels, pituitary (posterior lobe) extract raises the blood pressure; this is accompanied by a slowing of the pulse rate. Its main uses are in midwifery, in post-operative ileus, in diabetes insipidus, and to raise the blood pressure of persons suffering from shock.

In midwifery, pituitary (posterior lobe) extract is used mainly after the delivery of the child to prevent hæmorrhage; it appears to cause great constriction of the blood vessels in the uterus at the placental site. It is also used before the birth of the child, when the *os uteri* is fully dilated, to assist the contractions of a sluggish uterus. For this purpose the dose should not exceed 2 units. In midwifery, before the delivery of the child, the dose is 2 units, and for post-partum hæmorrhage, 5 units.

In post-operative intestinal stasis, or paralytic ileus, pituitary (posterior lobe) extract is of value in assisting the intestines to recommence peristalsis, and to cause evacuation of the bowels after an abdominal operation. In diabetes insipidus, the patient excretes a large volume of very dilute urine, and drinks large quantities of water to replace the loss. The injection of pituitary (posterior lobe) extract results in the excretion of a much smaller volume of more concentrated urine. In diabetes insipidus, doses of 10 units or more are often needed. The extract is used to raise the blood pressure in the treatment of surgical shock, but its value for this purpose is doubtful. For intravenous

injection in the treatment of shock, the extract should be diluted with normal saline solution. Pituitary (posterior lobe) extract can be administered by application on pledgets of wool to the back of the nose, where it is absorbed through the nasal mucous membrane, but accuracy of dosage is not possible by this route.

Dose.— 2 to 5 units (0.2 to 0.5 millilitre), by subcutaneous injection.

OXYTOCIC PRINCIPLE OF THE PITUITARY POSTERIOR LOBE is a solution of the separated active principle which possesses the power of stimulating the musculature of the uterus and is almost without effect on the blood pressure.

PRESSOR PRINCIPLE OF THE PITUITARY POSTERIOR LOBE is a solution of the separated active principle which has little action on the uterus but raises the blood pressure, relieves the polyuria of diabetes insipidus and also relieves post-operative intestinal stasis.

PITUITARY (ANTERIOR LOBE) EXTRACT is the active extract of the anterior lobe, commonly made for experimental purposes by allowing the minced fresh tissues to stand overnight with N/40 sodium hydroxide; the next day the reaction is adjusted to pH 7.2, and a clear fluid obtained by using a centrifuge. This crude extract can be purified by precipitating protein with sodium sulphate, and the clear fluid may be sterilised by passing it through a bacteria-proof filter. An extract so prepared has three important properties. When injected, it can accelerate growth in the young animal, or cause the fully grown animal to begin to grow again; it can bring about precocious sexual maturity in young female rats which have just been weaned; it can cause menstruation in monkeys. The phenomenon of precocious sexual maturity in the young animal is manifested by the ripening of egg-follicles in the ovaries, by ovulation and by the formation of corpora lutea. An extract having the properties of stimulating the growth of the ovarian follicles and the corpora lutea, when injected into immature female rats, may be obtained from the urine of pregnant women, which contains, in addition to oestrin, a hormone closely resembling the gonadotropic hormone of the anterior pituitary and called the anterior-pituitary-like hormone. The active substance can be precipitated by phosphotungstic acid in presence of sulphuric acid, after removal of protein from the urine by the addition of sulphosalicylic acid. The phosphotungstic acid precipitate is extracted with dilute ammonia, which dissolves the active substance. The excess of phosphotungstic acid is removed and the active substance precipitated by alcohol, dehydrated by alcohol and ether, and dried. For use, it is dissolved in water and adjusted to pH 7.0 to 7.5. Injection of anterior pituitary sex hormone, in small repeated doses, into immature female rats causes precocious sexual development, shown by enlargement and rupture of the ovarian follicles with discharge of the ova, followed by the development of corpora lutea. At present there is insufficient evidence to say whether these effects are produced by one or by two hormones, but the balance of experimental evidence points to the conclusion that there is only one hormone responsible for both effects, small doses producing ripening of the follicles and large doses producing the formation of corpora lutea. The solution does not produce oestrus in ovariectomised rats (distinction from oestrin), nor does it stimulate the growth of the follicles in hypophysectomised animals. A solution of the anterior pituitary sex hormone, in relatively small doses, has been suggested for use in functional amenorrhoea, and, in larger doses, in metrorrhagia and menorrhagia. It is also employed in the treatment of climacteric haemorrhage and threatened abortion. The potency of the solution is judged by the amount necessary to cause the formation of corpora lutea when injected into immature female rats. The age of the rats and the time at which they normally become sexually mature influence the results of the assay. The technique differs in different laboratories and no international standard has yet been adopted. In addition to the growth-promoting and gonadotropic actions, the anterior lobe of the pituitary gland is believed to elaborate other hormones which exert actions on the thyroid gland, the parathyroid glands, the pancreas and the mammary glands.

EXTRACTUM SUPRARENALI CORTICIS**(Ext. Suprarenal. Cort.)****Extract of Suprarenal Cortex***Synonym*—Cortin.

Extract of suprarenal cortex is an extract containing the specific principle of suprarenal cortex which, when injected, prolongs the life of cats or dogs from which the suprarenal glands have been removed. Fresh minced glands are extracted with alcohol (95 per cent.) and the extract is concentrated by removal of alcohol under reduced pressure between 50° and 60°. The concentrate is extracted with benzene and the benzene removed at a temperature between 45° and 50°. The residue is treated with acetone and the acetone removed at the same temperature. The residue from the acetone solution is further purified by shaking with a mixture of 30 millilitres of light petroleum, 74 millilitres of alcohol (95 per cent.) and 26 millilitres of water; the light petroleum dissolves inert material, while the active material dissolves in the alcohol. The alcoholic solution is concentrated and distilled water is added to the concentrate. When this solution is allowed to stand in the refrigerator, a deposit forms; this is removed by means of a centrifuge, the supernatant fluid is decanted and sterilised by filtration through a bacteria-proof filter. The extract should be free from more than traces of adrenaline. It does not contain vitamin C.

Standard.—The extract may be standardised by its power to keep cats or dogs alive when both suprarenal glands have been removed; an extract efficiently prepared should do this when 1 millilitre is given twice a day by subcutaneous injection.

Action and Uses.—Extract of suprarenal cortex is used in the treatment of Addison's disease, which is associated with degenerative changes in the cortex of the suprarenal gland. The use of suprarenal cortex extract must be regarded as substitution therapy, in much the same way as that of insulin in diabetes mellitus. It supplies presumably a hormone which is deficient or absent in cases of Addison's disease and which appears to be intimately connected with sodium metabolism. Its administration in adequate dosage is followed by disappearance of nearly all the signs and symptoms characteristic of the disease, such as asthenia, anæmia, nausea, wasting, lethargy, pigmentation, etc. It is **administered** by subcutaneous, intramuscular, or intravenous injection. During the acute stage of crisis, 10 to 20 millilitres, or more, should be injected intravenously, together with large doses of normal saline and dextrose to prevent dehydration. Maintenance doses may be given subcutaneously or intramuscularly; the injection should be made slowly, or 1 per cent. of procaine hydrochloride added to the dose in order to minimise pain. Usually a high blood urea is a warning of severe insufficiency and of the need for increased dosage, but a normal blood urea is no guarantee that a crisis is not imminent. Similarly, low blood sugar, high

blood calcium and high blood phosphate are warning signs for increased dosage. It may be necessary to continue indefinitely the administration of the extract daily or several times a week. There is some evidence, however, that adequate doses appear to improve the function of the unaffected remnant of the gland, so that in some cases the maintenance dose can be reduced, and in others the treatment may be discontinued for several months. The dose must be doubled during an infection. In some cases of Addison's disease doses of sodium chloride, from 10 to 15 grammes daily, have been given instead of or to supplement extract of suprarenal cortex. Extract of suprarenal cortex is used also in the treatment of some types of neurasthenia associated with low blood pressure, low blood sugar and subnormal temperature, in doses of 2 millilitres intravenously.

Dose.—5 to 10 millilitres ($1\frac{1}{4}$ to $2\frac{1}{2}$ fluid drachms).

FEL BOVINUM

(Fel Bov.)

Ox Bile

Ox bile is obtained from *Bos taurus* Linn. (Fam. Bovidae), and should be used when fresh. It occurs as a brownish or dark green, somewhat viscid liquid, with a disagreeable odour and an unpleasant, bitter taste. The specific gravity is about 1.02. Ox bile is neutral or faintly alkaline to litmus. When 0.1 gramme is dissolved in 10 millilitres of water, 0.1 gramme of sucrose dissolved in 1 millilitre of the solution, 3 millilitres of phosphoric acid added, and the mixture warmed on a water-bath, a reddish-violet to deep violet colour is produced. Ox bile contains the bile salts, sodium glycocholate and taurocholate, and the bile pigments, bilirubin, biliverdin, etc.; a mucinoid substance (nucleo-protein) is also present, together with small quantities of lecithin, cholesterol, fats, soaps, urea and mineral salts, of which the most important are sodium chloride, and calcium, iron and magnesium phosphates.

Action and Uses.—Ox bile is a cholagogue and laxative. It assists the action of the pancreatic secretion upon fats and promotes their assimilation. It is given medicinally in chronic constipation, in conditions of biliary deficiency and in intestinal dyspepsia,* often with pancreatin. Ox bile increases peristalsis slightly, and an enema is sometimes used, containing $\frac{1}{4}$ to 1 fluid ounce in 2 fluid ounces of warm water, to remove impacted fæces; such an enema is employed in paralytic ileus. Bile assists the action of such purgatives as jalap, aloes and rhubarb. For internal use, *Extractum Fellis Bovini* is preferred; it is best administered in capsules coated with keratin, or treated with solution of formaldehyde, and it may also be given in keratin-coated pills. It is also used as a dry powder, one part of which is equivalent to eight parts of ox bile. Ox bile is employed as a constituent of bacteriological culture media for the isolation of the typhoid group of bacteria.

Preparation

Extractum Fellis Bovini, B.P.—(Ext. Fell. Bov.)—Extract of Ox Bile. *Syn.*—*Fel Bovinum Purificatum*; Purified Ox Bile. Fresh ox bile is evaporated and shaken with alcohol, then set aside until the precipitate has subsided and the clear liquid evaporated to a firm extract. It should be stored in well-closed containers. Dose.—0·3 to 1 gramme (5 to 15 grains).

FERRI ARSENAS

(Ferr. Arsen.)

Iron Arsenate*Synonym*—Arseniate of Iron.

Iron arsenate may be prepared by the following process:—Dissolve 41·5 parts of ferrous sulphate in about 240 parts of boiling distilled water, and 53 parts of anhydrous sodium arsenate in about 200 parts of boiling water, and mix the two solutions; dissolve 9 parts of sodium bicarbonate in a little cold water, add the solution to the hot mixture and stir thoroughly; wash the precipitate formed on a calico filter until free from sulphates, remove most of the water it contains by pressure, and dry at a temperature not exceeding 40°. The product consists of ferrous arsenate, with ferric arsenate and some ferric oxide. It occurs as a greenish, amorphous, tasteless powder.

Insoluble in water; readily soluble in hydrochloric acid.

Standard.—Iron arsenate contains not less than 10 per cent. of ferrous iron calculated as $\text{Fe}_3(\text{AsO}_4)_2$. 0·5 gramme complies with the limit test for sulphates.

Assay.—Dissolve about 2·5 grammes, accurately weighed, in 10 millilitres of dilute sulphuric acid and 30 millilitres of recently boiled and cooled water, and titrate with N/10 potassium permanganate; each millilitre of N/10 potassium permanganate is equivalent to 0·01485 gramme of $\text{Fe}_3(\text{AsO}_4)_2$.

Action and Uses.—The medicinal properties of iron arsenate are principally those of the arsenate ion; the amount of iron in each dose is small. The salt is best **administered** in pill form, being well triturated with a small quantity of lactose and massed with syrup of liquid glucose.

Dose.—0·004 to 0·016 gramme ($\frac{1}{16}$ to $\frac{1}{4}$ grain).

FERRI CARBONAS SACCHARATUS

(Ferr. Carb. Sacch.)

Saccharated Iron Carbonate

Saccharated iron carbonate consists of a mixture of ferrous carbonate, which may be partly oxidised, and glucose. It is prepared, as described

in the British Pharmacopœia, by adding an aqueous solution of ferrous sulphate and liquid glucose to a solution of sodium carbonate; the mixture is diluted, and the precipitate washed, drained, mixed with liquid glucose, and dried at a temperature not exceeding 100°. It occurs as an olive-brown, slightly hygroscopic powder with a faintly chalybeate taste, and gives the reactions of iron, carbonates and dextrose. It should be **stored** in well-closed containers.

Partially **soluble** in water.

Standard, B.P.—Saccharated iron carbonate contains not less than 50 per cent. of ferrous iron, calculated as ferrous carbonate, FeCO_3 . Arsenic limit, 5 parts per million. It complies also with a limit test for sulphate.

Action and Uses.—Saccharated iron carbonate is a non-astringent chalybeate having the general properties of iron salts (see Ferri Sulphas). It is prescribed for anæmia and chlorosis, and is a suitable preparation for administration to children. It may be **administered** in cachets, pills, tablets, or capsules.

Dose.—0·6 to 2 grammes (10 to 30 grains).

FERRI OXIDUM SACCHARATUM.—Saccharated iron oxide may be prepared by precipitating a solution of ferric chloride with sodium carbonate, dissolving the precipitated ferric hydroxide in sucrose and sodium hydroxide solution, evaporating, and mixing the residue with sucrose. It occurs as a reddish-brown powder having a slightly ferruginous taste, and containing about 2·9 per cent. of iron. It is soluble in hot water. Saccharated iron oxide has properties similar to those of saccharated iron carbonate, and may be administered in the same dosage.

Preparations

Pilulæ Ferri Carbonatis Saccharati, B.P.C.—(Pil. Ferr. Carb. Sacch.)—Saccharated Ferrous Carbonate Pills. Each pill contains 3 grains of saccharated ferrous carbonate, and is approximately equivalent to 10 grains of pill of iron carbonate. Dose.—1 to 3 pills.

Tabellæ Ferri Carbonatis, B.P.C.—(Tab. Ferr. Carb.)—Tablets of Iron Carbonate. *Syn.*—Blaud's Tablets. Each tablet is approximately equivalent to 5 grains of pill of iron carbonate. Dose.—1 to 6 tablets.

Tabellæ Ferri Carbonatis et Aloini, B.P.C.—(Tab. Ferr. Carb. et Aloin.)—Tablets of Iron Carbonate and Aloin. *Syn.*—Blaud's Tablets with Aloin. Each tablet is approximately equivalent to 5 grains of pill of iron carbonate and contains also $\frac{1}{10}$ grain of aloin. Dose.—1 to 6 tablets.

FERRI ET AMMONII CITRAS

(Ferr. et Ammon. Cit.)

Iron and Ammonium Citrate

Iron and ammonium citrate is a complex ferric ammonium citrate of uncertain composition. It may be prepared by the following process:—Dilute 100 parts of solution of ferric sulphate with four times its volume of distilled water, and add it to 160 parts of

dilute solution of ammonia previously diluted with 400 parts of distilled water, stirring constantly and briskly, and taking care that ammonia is finally in slight excess, as indicated by the odour; set aside the mixture for two hours, stirring occasionally; collect the precipitated ferric hydroxide, wash with distilled water until free from sulphates, and drain well. Dissolve 40 parts of citric acid in an equal weight of water, heat on a water-bath, add the ferric hydroxide, and stir until it has nearly all dissolved, or until the citric acid is saturated with ferric hydroxide, more being prepared, if necessary, from solution of ferric sulphate. Allow to cool, add 55 parts of dilute solution of ammonia, filter, evaporate to a thin syrup, maintaining a very slight excess of ammonia, and scale on porcelain tiles or sheets of glass at a temperature not exceeding 40°. It occurs in thin, dark red, transparent, deliquescent scales, with an astringent taste. It gives the reactions of ammonium salts and of citrates, and the residue after gentle ignition gives the reactions of iron. It should be **stored** in well-closed containers and protected from light.

Soluble in water (2 in 1); almost insoluble in alcohol (90 per cent.).

Standard, B.P.—Iron and ammonium citrate contains not less than 20·5 per cent. and not more than 22·5 per cent. of Fe. Arsenic limit, 5 parts per million. It complies also with a limit test for sulphate.

Action and Uses.—Iron and ammonium citrate has the general properties of iron salts, and is one of the most useful and most frequently prescribed of such preparations. It is one of the least astringent compounds of iron, and is often well borne when astringent preparations of iron disagree. It is used in the treatment of the microcytic hypochromic anæmias, and the effective dose may often be as large as 2 grammes (30 grains) given three times a day. It is best **administered** in mixture form, flavoured with syrup of orange and chloroform water. Without chloroform water or spirituous tinctures, solutions of iron and ammonium citrate do not keep well. For the preparation of solutions for hypodermic injection, the green variety (*Ferri et Ammonii Citras Viridis*) is usually employed. Iron and ammonium citrate is **in-compatible** with mineral acids, fixed alkalis and vegetable astringents.

Dose.—0·3 to 1 gramme (5 to 15 grains).

FERRI CITRAS.—Iron citrate may be prepared by dissolving freshly precipitated ferric hydroxide in a solution of citric acid, evaporating and scaling. It occurs in thin, transparent scales of a garnet-red colour and contains about 16 per cent. of iron. It should be stored in well-stoppered bottles and protected from light. It is slowly soluble in water, more readily soluble in hot water, and insoluble in alcohol. Iron citrate has properties similar to those of iron and ammonium citrate. It may be dispensed in cachets, and is specially suitable for use in acid solutions. **Dose.**—0·3 to 1 gramme (5 to 15 grains).

FERRI ET AMMONII TARTRAS.—Iron and ammonium tartrate may be prepared by dissolving freshly precipitated ferric hydroxide in a solution of ammonium tartrate and tartaric acid, evaporating and scaling. It occurs in thin, transparent, garnet-red to reddish-brown, odourless scales, having a sweetish, slightly ferruginous

taste; it is slightly deliquescent and contains about 13 per cent. of iron. It is very soluble in water, and insoluble in alcohol. Iron and ammonium tartrate has properties similar to those of iron and ammonium citrate. Dose.—0·3 to 1 gramme (5 to 15 grains).

Preparation

Vinum Ferri Citratis, B.P.C.—(Vin. Ferr. Cit.)—Iron Citrate Wine. Iron and ammonium citrate dissolved in orange wine; 4 fluid drachms contains about 4 grains of iron and ammonium citrate. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

This wine was included in the British Pharmacopœia, 1914.

FERRI ET AMMONII CITRAS VIRIDIS

(Ferr. et Ammon. Cit. Vir.)

Green Iron and Ammonium Citrate

Green iron and ammonium citrate is made in the same way as iron and ammonium citrate, but a larger proportion of citric acid is used and only sufficient ammonia is added to produce a green solution. It occurs in green, deliquescent scales. Its solution is slightly acid in reaction. In other respects it has the characters of iron and ammonium citrate. It should be **stored** in well-closed containers and protected from light.

Soluble in water (2 in 1).

Standard.—Green iron and ammonium citrate, determined by the method of the British Pharmacopœia for Ferri et Ammonii Citras, contains not less than 14 per cent. and not more than 16 per cent. of Fe. Arsenic limit, 5 parts per million. Lead limit, 50 parts per million. 0·2 gramme, dissolved in 5 millilitres of water and boiled for one minute with 2 millilitres of hydrochloric acid, complies with the limit test for sulphates. 1 gramme dissolved in 25 millilitres of water requires not more than 4 millilitres of N/2 sodium hydroxide for neutralisation to phenolphthalein (limit of acidity).

Action and Uses.—Green iron and ammonium citrate is a suitable form for the hypodermic administration of iron. Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. They should be stored protected from light. A 4 per cent. solution in sterilised water may be injected deeply, in doses of 0·5 to 1 millilitre (8 to 15 minims), every second or third day. The solution must be neutralised previously by adding ammonia until the mixture gives no red colour with methyl red or phenol red. The value of iron administered by injection is very doubtful; it appears to be absorbed after intramuscular injection even more slowly than after oral administration. There is, in fact, definite clinical evidence that the oral administration of iron in large doses is more effective than iron administered by injection in the treatment of hypochromic anæmias. The effective

dose of *Injectio Ferri* to cure an anæmia of ordinary severity appears to be 4 millilitres (equivalent to 14 milligrams of metallic iron) twice daily for about six weeks. The minimal toxic dose is the equivalent of about 48 milligrams of metallic iron. There is, moreover, evidence that harmful effect on the kidneys can be produced by injections of iron salts.

Dose.—0·3 to 0·6 gramme (5 to 10 grains).

Preparations

Injectio Ferri, B.P.—(*Inj. Ferr.*)—Injection of Iron. A sterile solution containing a double citrate of iron and ammonium. 2 millilitres contains the equivalent of about 0·007 gramme of iron, or of about 0·033 gramme of iron and ammonium citrate, and 30 minims contains the equivalent of about $\frac{1}{10}$ grain of iron or of about $\frac{1}{2}$ grain of iron and ammonium citrate. **Dose.**—1 to 2 millilitres ($\frac{1}{4}$ to $\frac{1}{2}$ fluid drachm), by intramuscular injection.

Injectio Ferri et Arseni, B.P.C.—(*Inj. Ferr. et Arsen.*)—Injection of Iron and Arsenic. It is of the same strength as injection of iron but contains also arsenic trioxide; 1 millilitre contains 0·0013 gramme, and 15 minims contains about $\frac{1}{80}$ grain, of arsenic trioxide. **Dose.**—0·5 to 1 millilitre (8 to 15 minims), by intramuscular injection.

FERRI ET AMMONII CITRO-ARSENIS

(*Ferr. et Ammon. Citro-Arsen.*)

Iron and Ammonium Citro-Arsenite

Synonyms.—*Ferri Citro-arsenis Ammoniatatus*; Ammoniated Citro-arsenite of Iron; Soluble Iron Arsenite.

Iron and ammonium citro-arsenite is a double salt of ferrous arsenite and ammonium citrate. It may be prepared by adding an ammoniacal solution of arsenic trioxide to a solution of green iron and ammonium citrate, evaporating on glass plates and scaling. In the process of scaling, part of the arsenic trioxide is oxidised to the arsenic condition. It occurs in green or yellowish-green, deliquescent scales, containing about 14 per cent. of iron and the equivalent of about 1·4 per cent. of arsenic trioxide.

Very **soluble** in water.

Action and Uses.—Iron and ammonium citro-arsenite is given by intramuscular injection in the treatment of anæmia. Solutions of the salt have been employed in leucæmia. It is preferably injected into the muscles of the gluteal region. *Injectio Ferri et Arseni* is a suitable form for administration by injection. Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration; they should be stored protected from light.

Dose.—0·0015 to 0·03 gramme ($\frac{1}{40}$ to $\frac{1}{2}$ grain); maximum daily dose, 0·06 gramme (1 grain).

FERRI ET MANGANI CITRAS

(Ferr. et Mang. Cit.)

Iron and Manganese Citrate

Iron and manganese citrate may be prepared by dissolving freshly precipitated ferric hydroxide and hydrated manganese oxide in solution of citric acid, evaporating the solution, scaling and drying. It occurs in reddish-brown scales and should be **stored** in well-closed containers.

Soluble in water.

Standard.—Iron and manganese citrate contains not less than 14 per cent. of Fe, and not less than 7 per cent. of Mn. Arsenic limit, 5 parts per million. Lead limit, 50 parts per million.

Assay.—For iron. Proceed by the method of the British Pharmacopœia for Ferri et Ammonii Citras, using about 0.7 gramme, accurately weighed.

For manganese. Dissolve 0.1 gramme in 25 millilitres of dilute nitric acid and boil gently until the solution is clear and oxides of nitrogen are removed. Add 12 millilitres of N/10 silver nitrate and 1 gramme of ammonium persulphate, continue heating for thirty seconds after oxidation begins and bubbles of oxygen rise freely, cool, and titrate with N/100 sodium arsenite until the pink colour disappears; each millilitre of N/100 sodium arsenite is equivalent to 0.0011 gramme of Mn.

Action and Uses.—Iron and manganese citrate is used in the treatment of secondary anaemia and chlorosis. It has been suggested that, as is the case with copper, the presence of manganese may increase the haemoglobin-forming properties of the iron. Iron and manganese citrate is usually **administered** in solution.

Dose.—0.2 to 1 gramme (3 to 15 grains).

FERRI ET POTASSII TARTRAS

(Ferr. et Pot. Tart.)

Iron and Potassium Tartrate

Synonyms.—Ferrum Tartaratum; Tartarated Iron.

Iron and potassium tartrate may be prepared by the following process:—Dilute 100 parts of solution of ferric sulphate with four times its volume of distilled water, and add to it 160 parts of solution of ammonia diluted with 400 parts of distilled water, to precipitate ferric hydroxide as directed under Ferri et Ammonii Citras. Mix the well-drained precipitate of ferric hydroxide intimately with 1.25 parts of potassium acid tartrate, set aside for twenty-four hours and then heat the mixture to a temperature not exceeding 60°; add gradually 200 parts of distilled water, stir constantly until nothing more

will dissolve, and filter the solution. Finally, evaporate the liquid to a thin syrup at a temperature not exceeding 60° and scale on porcelain tiles or sheets of glass at a temperature not exceeding 40° . It occurs in thin, transparent, deep garnet-red scales, which are somewhat sweetish and ferruginous in taste. The aqueous solution, acidified with hydrochloric acid, yields a blue precipitate with potassium ferrocyanide solution. 1 gramme in 10 millilitres of water, boiled with a slight excess of potassium hydroxide solution, produces a reddish-brown precipitate, and the filtered solution, acidified with acetic acid, yields, on cooling, a crystalline deposit.

Slowly **soluble** in water (1 in 1); very sparingly soluble in alcohol (90 per cent.).

Standard.—Iron and potassium tartrate, determined by the method of the British Pharmacopœia for *Ferri et Ammonii Citras*, contains not less than 20 per cent. of Fe. Arsenic limit, 5 parts per million. Lead limit, 50 parts per million. 0.25 gramme dissolved in 5 millilitres of water and boiled with 2 millilitres of hydrochloric acid complies with the limit test for sulphates.

Action and Uses.—Iron and potassium tartrate is a mild chalybeate, similar in its properties to iron and ammonium citrate.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

FERRI ET QUININÆ CITRAS

(*Ferr. et Quinin. Cit.*)

Iron and Quinine Citrate

Iron and quinine citrate is a complex ammonium quinine ferric citrate and may be prepared by the following process:—Dilute 90 parts of solution of ferric sulphate with four times its volume of distilled water, and add it to about 144 parts of dilute solution of ammonia diluted with 360 parts of distilled water, to precipitate ferric hydroxide as directed under *Ferri et Ammonii Citras*. Mix 20 parts of quinine sulphate with 160 parts of distilled water, add 30 parts of dilute sulphuric acid and, when the salt is dissolved, precipitate the quinine by the addition of a slight excess of solution of ammonia; collect the precipitate and wash it with 600 parts of distilled water. Dissolve 61.5 parts of citric acid in an equal weight of water, heat on a water-bath, add the well-drained ferric hydroxide, stir until dissolved, then add the precipitated quinine and stir until dissolved. Allow to cool and add, in small quantities at a time, 30 parts of dilute solution of ammonia diluted with 40 parts of distilled water, stirring briskly and allowing the quinine which separates with each addition of ammonia to dissolve before the next addition is made. Then filter, evaporate to a thin syrup and scale on porcelain tiles or sheets of glass at a temperature not exceeding 40° . It occurs in thin, greenish-yellow, deliquescent

scales, with a bitter, chalybeate taste. The aqueous solution has an acid reaction and gives a precipitate of quinine when rendered alkaline by the addition of solution of ammonia. It gives the reactions of ammonium salts and of citrates, and the residue after gentle ignition gives the reactions of iron. It should be **stored** in well-closed containers and protected from light.

Soluble in water (2 in 1).

Standard, B.P.—Iron and quinine citrate contains not less than 14·5 per cent. and not more than 15·5 per cent. of anhydrous quinine, and not less than 12 per cent. and not more than 14 per cent. of Fe. Arsenic limit, 5 parts per million. It complies also with a limit test for sulphate.

Action and Uses.—Iron and quinine citrate is a bitter chalybeate, having the general properties of iron and quinine, and is much used as a tonic and stomachic. It may be **administered** in mixtures flavoured with syrup of orange or syrup of lemon and chloroform water, or in pills massed quickly with a sufficient quantity of diluted alcohol. When prescribed with arsenic, the acid solution of arsenic should be used. Iron and quinine citrate is **incompatible** with alkalis, alkali carbonates and citrates, and with vegetable astringents.

Dose.—0·3 to 1 gramme (5 to 15 grains).

Preparation

Vinum Ferri et Quininae, B.P.C.—(Vin. Ferr. et Quinin.)—Iron and Quinine Wine. Iron and quinine citrate dissolved in sherry-type wine; 4 fluid drachms contains about 4 grains of iron and quinine citrate. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

FERRI ET STRYCHNINÆ CITRAS

(Ferr. et Strych. Cit.)

Iron and Strychnine Citrate

Iron and strychnine citrate may be prepared by dissolving freshly precipitated ferric hydroxide and strychnine in citric acid, neutralising with ammonia, evaporating at a low temperature, and scaling. It occurs in thin, transparent, green scales, with a bitter, chalybeate taste, and is deliquescent in moist air. The aqueous solution is slightly acid to litmus and, although not immediately precipitated by ammonia, is rendered darker in colour. It yields a blue colour or precipitate only when acidified with hydrochloric acid and then treated with solution of potassium ferrocyanide.

Readily **soluble** in water; partly soluble in alcohol.

Standard.—Iron and strychnine citrate contains not less than 0·95 per cent. and not more than 1·05 per cent. of strychnine, and not less than 12 and not more than 14 per cent. of Fe. Arsenic limit, 5 parts per

million. 0·2 gramme, dissolved in 5 millilitres of water and boiled for one minute with 2 millilitres of hydrochloric acid, complies with the limit test for sulphates.

Assay.—For strychnine. Dissolve about 2·5 grammes, accurately weighed, in 45 millilitres of water, add 10 millilitres of dilute solution of ammonia and extract the alkaloid completely with successive portions of chloroform. Evaporate the chloroform nearly to dryness, add 1 millilitre of alcohol and evaporate to dryness; dry at 100° and weigh the strychnine.

For iron. Evaporate the aqueous liquid from the assay for strychnine and complete the assay by the method of the British Pharmacopœia for iron in *Ferri et Quininae Citras*.

Action and Uses.—Iron and strychnine citrate is used in mixture form as a bitter chalybeate in atonic dyspepsia and in anæmia.

Dose.—0·06 to 0·2 gramme (1 to 3 grains).

FERRI FORMAS

(*Ferr. Form.*)

Iron Formate

Synonym—Ferric Formate.

Iron formate, $\text{Fe}_3(\text{OH})_2(\text{H}\cdot\text{COO})_7, 4\text{H}_2\text{O}$, may be prepared by shaking freshly precipitated, moist ferric hydroxide with an excess of 25 per cent. aqueous solution of formic acid, collecting the crystals which separate, and drying in air. It occurs as fine needles or as a gritty powder, having a characteristic copper-red colour. Saturated solutions are liable to decompose in contact with air, with deposition of ferric hydroxide or basic formates.

Soluble in water (about 1 in 18), dehydrated alcohol (about 1 in 20).

Action and Uses.—Iron formate has the hæmatinic properties of other iron salts.

Dose.—0·06 to 0·3 gramme (1 to 5 grains).

FERRI GLYCEROPHOSPHAS

(*Ferr. Glycerophosph.*)

Iron Glycerophosphate

Synonym—Ferric Glycerophosphate.

Iron glycerophosphate may be obtained by dissolving freshly precipitated ferric hydroxide in glycerophosphoric acid in the presence of

alkali citrate, evaporating the solution and drying on glass plates at a temperature not exceeding 40°. It occurs as yellow or greenish-yellow scales.

Slowly **soluble** in water.

Standard.—Iron glycerophosphate contains not less than 13 per cent. and not more than 16 per cent. of Fe. Residue on ignition, not less than 42 per cent. Arsenic limit, 5 parts per million. Lead limit, 50 parts per million. 2 grammes dissolves in 5 millilitres of warm water, and the solution remains practically clear on dilution with 100 millilitres of cold water.

Assay.—Dissolve 1 gramme, accurately weighed, in 20 millilitres of water and 9 millilitres of hydrochloric acid, boil for fifteen seconds and cool; add 3 grammes of potassium iodide and titrate with N/10 sodium thiosulphate; each millilitre of N/10 sodium thiosulphate is equivalent to 0.005584 gramme of Fe.

Action and Uses.—Iron glycerophosphate has been recommended in neurasthenic conditions, also in secondary anæmias. The glycerophosphate portion is regarded as having no action of value and there is no reason to suppose that it possesses advantages over the simple phosphates. Iron glycerophosphate is contained in compound syrup of glycerophosphates, and may also be administered in pills or cachets. It is sometimes given hypodermically in doses of 0.03 gramme ($\frac{1}{2}$ grain). Solutions for **injection** may be sterilised by tyndallisation, by filtration, or by heating at 100° for thirty minutes. They should be stored protected from light.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

FERRI HYPOPHOSPHIS

(Ferr. Hypophosph.)

Iron Hypophosphite

Synonym—Ferric Hypophosphite.

Iron hypophosphite may be prepared by adding a solution of sodium hypophosphite to a solution of ferric chloride containing as little free acid as possible, washing, and drying at a moderate heat. It occurs as a white or greyish-white, odourless and nearly tasteless powder. On ignition, it evolves spontaneously inflammable hydrogen phosphide gas and leaves a residue of ferric pyrophosphate.

Slightly **soluble** in water, more readily in presence of hypophosphorous acid, and, when freshly prepared, in a warm concentrated solution of alkali citrate forming a green solution.

Standard.—Iron hypophosphite contains not less than 97 per cent. and not more than the equivalent of 101 per cent. of $\text{Fe}(\text{H}_2\text{PO}_2)_3$,

calculated on the salt dried at 100°. Loss on drying at 100°, not more than 5 per cent.

Assay.—Dissolve about 1 gramme, accurately weighed, in hydrochloric acid and dilute to 100 millilitres; transfer 10 millilitres to a stoppered bottle, add 20 millilitres of hydrochloric acid, 2 grammes of potassium iodide and 50 millilitres of N/10 iodine; allow to stand in the dark for four hours and then titrate the excess of iodine with N/10 sodium thiosulphate; each millilitre of N/10 iodine is equivalent to 0.005019 gramme of $\text{Fe}(\text{H}_2\text{PO}_2)_3$.

Action and Uses.—Iron hypophosphite has the hæmatinic properties of iron salts, and is used in combination with other salts of hypophosphorous acid in wasting diseases, but has no advantage over iron salts generally. It is sometimes administered in pills or cachets, and in the form of solution it is a constituent of compound syrup of hypophosphites.

Dose.—0.06 to 0.2 gramme (1 to 3 grains).

Preparations

Liquor Ferri Hypophosphitis, B.P.C.—(Liq. Ferr. Hypophosph.)—Solution of Iron Hypophosphite. *Syn.*—Liquor Ferri Hypophosphitis Fortis; Strong Solution of Iron Hypophosphite. It contains the equivalent of from 8.5 to 10.5 per cent. w/v of ferric hypophosphite. *Dose.*—0.6 to 2 millilitres (10 to 30 minims).

Syrupus Ferri Hypophosphitis, B.P.C.—(Syr. Ferr. Hypophosph.)—Syrup of Iron Hypophosphite. Solution of iron hypophosphite, 1 in 5, in syrup; each fluid drachm contains about 1 grain of ferric hypophosphite. *Dose.*—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

FERRI IODIDUM

(Ferr. Iod.)

Iron Iodide

$\text{FeI}_2 = 309.7$

Synonym—Ferrous Iodide.

Iron iodide may be prepared by mixing 6 parts of iron with 17 parts of iodine and 20 parts of water, controlling the heat developed as combination takes place, in order to avoid loss of iodine, and, when the reaction is complete, heating until the solution becomes pale green. The solution is filtered while hot and rapidly evaporated in a bright iron vessel until it solidifies on cooling. When solid, it should be transferred at once to a hot, dry, stoppered bottle. It occurs as a steel-grey or reddish-brown, crystalline mass which melts at about 177°, giving off vapours of iodine. It readily becomes oxidised and should be **stored** in small, well-stoppered bottles.

Readily **soluble** in water, forming a green-coloured solution; soluble in glycerin and alcohol.

Action and Uses.—Ferrous iodide has the general properties of iron and of iodine. It is used especially in tuberculous and syphilitic conditions and is best **administered** in the form of Syrupus Ferri Iodidi. If required in solid form, it may be dispensed in pills made with the freshly prepared salt by rubbing with powdered liquorice and massing with syrup of liquid glucose.

Dose.—0·06 to 0·3 gramme (1 to 5 grains).

Preparations

Liquor Ferri Iodidi, B.P.C.—(Liq. Ferr. Iod.)—Solution of Ferrous Iodide. It contains from 53·1 to 54·2 per cent. w/v of FeI_2 , and when diluted with seven times its volume of syrup, the product is equivalent to Syrupus Ferri Iodidi B.P. **Dose.**—0·12 to 0·5 millilitre (2 to 8 minims).

Syrupus Ferri Iodidi, B.P.—(Syr. Ferr. Iod.)—Syrup of Ferrous Iodide. *Syn.*—Syrupus ferrosi iodidi concentratus I.A. It is prepared from iron, iodine, dilute hypophosphorous acid, distilled water and syrup, and contains 5 per cent. w/w of FeI_2 (limits, 4·75 to 5·25). 8 millilitres contains about 0·56 gramme of ferrous iodide, equivalent to about 0·1 gramme of iron; 2 fluid drachms contains about $7\frac{1}{2}$ grains of ferrous iodide, equivalent to about $1\frac{1}{2}$ grains of iron. It may be prepared by diluting 1 volume of solution of ferrous iodide with sufficient syrup to yield 8 volumes. It should be stored in well-filled, well-closed bottles of clear, white glass and exposed to light. **Dose.**—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Syrupus ferrosi iodidi dilutus I.A. contains 0·5 per cent. w/w of ferrous iodide.

FERRI LACTAS

(Ferr. Lact.)

Iron Lactate

Synonym—Ferrous Lactate.

Iron lactate, $(\text{CH}_3\cdot\text{CHOH}\cdot\text{COO})_2\text{Fe} \cdot 3\text{H}_2\text{O}$, may be prepared by digesting iron filings with lactic acid until interaction ceases, filtering and crystallising, or by decomposing a solution of calcium lactate with a solution of ferrous sulphate, filtering, removing residual calcium sulphate from the filtrate by means of alcohol, again filtering, evaporating and crystallising. It occurs as a greenish-white, crystalline powder, or in small, needle-shaped crystals and crystalline masses. It has a characteristic, but not strongly marked, odour, and a sweet, mildly chalybeate taste. Its solutions have a slightly acid reaction. On heating, iron lactate becomes brown, then black, and froths, evolving white, acrid vapours, and finally leaving a residue of ferric oxide. Iron lactate should be **stored** in well-stoppered bottles protected from light.

Soluble in water (1 in 40), boiling water (1 in 12), freely soluble, with formation of a green colour, in solutions of alkali citrates; almost insoluble in alcohol, although it may be crystallised from hot diluted alcohol.

Standard.—Iron lactate yields on ignition not less than 26·5 and not more than 28·5 per cent. of residue. Arsenic limit, 5 parts per million. 0·5 gramme complies with the limit test for sulphates. A 2 per cent. solution produces no opalescence on the addition of lead acetate solution (limit of tartaric, citric and malic acids). Boil 0·5 gramme dissolved in 20 millilitres of water with 5 millilitres of dilute solution of ammonia and filter; the filtrate, after evaporation and ignition, yields a residue which weighs not more than 0·005 gramme (limit of calcium and alkali salts). Dissolve 1 gramme in 5 millilitres of water and add 5 millilitres of hydrochloric acid and 1 gramme of potassium iodide; the iodine liberated requires for decolourisation not more than 1·5 millilitres of N/10 sodium thiosulphate (limit of ferric iron).

Action and Uses.—Iron lactate has the general properties of iron salts (see *Ferri Sulphas*); it is very readily assimilated and is one of the least astringent forms of iron. The powder may be administered in cachets, combined, if so desired, with bismuth, pepsin, or *nux vomica*. It is given to children as *Syrupus Calcii Lactophosphatis cum Ferro*.

Dose.—0·12 to 0·6 gramme (2 to 10 grains).

Preparation

Syrupus Calcii Lactophosphatis cum Ferro, B.P.C.—(*Syr. Calc. Lactophosph. c. Ferr.*)—Syrup of Calcium Lactophosphate with Iron. Each fluid drachm contains about $\frac{1}{2}$ grain of iron lactate, with potassium citrate and distilled water, in syrup of calcium lactophosphate. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

FERRI OXIDUM PRÆCIPITATUM FUSCUM

(*Ferr. Oxid. Præcip. Fusc.*)

Brown Precipitated Ferric Oxide

Synonyms.—*Ferri Peroxidum*; *Ferri Peroxidum Hydratum*; *Ferrugo*; *Brown Hydrated Oxide of Iron*.

Brown precipitated ferric oxide is prepared by precipitation from a solution of ferric sulphate with solution of ammonia or of a fixed alkali, washing the precipitate until nearly free from sulphates, and drying at a temperature not exceeding 100°. It occurs as a brown powder containing from 80 to 90 per cent. of ferric oxide. It dissolves completely, although slowly, in hydrochloric acid diluted with an equal volume of water.

Standard.—Brown precipitated ferric oxide loses, on ignition at a dull red heat, not less than 10 per cent. and not more than 20 per cent. of its weight. Arsenic limit, 5 parts per million. The solution obtained by extracting 0·25 gramme with water complies with the limit test for sulphates. When 1 gramme is dissolved in hydrochloric acid, excess of ammonia added and the precipitate removed by filtration, the filtrate

is colourless (limit of copper), and is not rendered turbid by the addition of hydrogen sulphide solution (limit of zinc). The solution in a mixture of equal volumes of hydrochloric acid and water does not give a blue colour or precipitate with potassium ferricyanide solution (absence of ferrous salts).

Action and Uses.—Brown precipitated ferric oxide is employed medicinally for the same purposes as red oxide of iron.

Dose.—0.3 to 1 gramme (5 to 15 grains).

FERRI OXIDUM CALCINATUM.—Calcined iron oxide, commonly known as Ferri Sesquioxidum, may be obtained by roasting precipitated oxide of iron, or by roasting ferrous sulphate. When freshly prepared, it contains about 97 per cent. of ferric oxide, but, as usually met with, it contains about 94 per cent. It is not readily soluble in hydrochloric acid, but will dissolve on prolonged boiling. Impure ferruginous earths and other forms of ferric oxide used in the arts are known as Armenian bole ("Bole Armen"), ochre, sienna, Venetian red, colcothar, caput mortuum, vitrioli, tripoli, crocus ferri, crocus martis, polishing crocus and jewellers' rouge.

FERRI OXIDUM MAGNETICUM.—Magnetic iron oxide, commonly known as ferroso-ferric oxide, or black oxide of iron, occurs as a crystalline ore. The product obtained by precipitation from solution of ferrous and ferric salts is of indefinite composition and contains small and variable amounts of ferrous iron. It is insoluble in water or alcohol and soluble in warm diluted acids.

Preparation

Emplastrum Ferri, B.P.C.—(Emp. Ferr.)—Iron Plaster. *Syn.*—Emplastrum Roborans; Strengthening Plaster. Brown precipitated ferric oxide, about 9 per cent., with Burgundy pitch and plaster of lead.

FERRI OXIDUM PRÆCIPITATUM RUBRUM

(Ferr. Oxid. Præcip. Rub.)

Red Precipitated Ferric Oxide

Synonyms—Ferri Carb.; Ferri Subcarb.; Red Hydrated Oxide of Iron.

Red precipitated ferric oxide is prepared by precipitating a solution of ferrous sulphate with sodium carbonate, washing the precipitate until nearly free from sulphates, and drying at a temperature not exceeding 100°. It undergoes almost complete oxidation during the process of washing and drying, and occurs as a dull red powder. It is completely soluble in hydrochloric acid diluted with an equal volume of water, but only with difficulty in weaker acid. There is usually considerable interference during solution, owing to traces of carbonate, and the resulting solution gives a copious blue precipitate with potassium ferricyanide, due to traces of ferrous salt.

Standard.—Red precipitated ferric oxide loses, on ignition at a dull red heat, not less than 10 per cent. and not more than 20 per cent. of its weight. Arsenic limit, 5 parts per million. The solution obtained by extracting 0.25 gramme with water complies with the limit test for

sulphates. When 1 gramme is dissolved in hydrochloric acid, excess of ammonia added, and the precipitate removed by filtration, the filtrate is colourless (limit of copper), and is not rendered turbid by the addition of hydrogen sulphide solution (limit of zinc).

Action and Uses.—Red precipitated ferric oxide is employed as a hæmatinic in the treatment of secondary anæmia. It may be used as an antidote to arsenic, but the freshly precipitated hydroxide is preferable. It is also used for tinting zinc compounds in the preparation of calamine.

Dose.—0·3 to 1 gramme (5 to 15 grains).

FERRI PERCHLORIDUM

(Ferr. Perchlor.)

Ferric Chloride

Synonym—Iron Perchloride.

Ferric chloride may be prepared by the evaporation of a slightly acid solution of ferric chloride, and setting aside until a crystalline mass forms which is at once transferred to a well-stoppered bottle protected from light. It occurs as an orange-coloured, very deliquescent, crystalline mass, having a slight odour of hydrochloric acid and a very astringent, metallic taste. It melts at about $35\cdot5^\circ$, and at a higher temperature is partly decomposed and partly volatilised. Anhydrous ferric chloride ($\text{FeCl}_3 = 162\cdot2$), formed as a sublimate by heating metallic iron in a stream of chlorine, occurs in dark greenish-brown crystals which are exceedingly deliquescent.

Readily **soluble** in water, alcohol, ether and glycerin.

Standard.—Ferric chloride, determined by the method of the British Pharmacopœia for *Liquor Ferri Perchloridi*, contains not less than 57 per cent. and not more than 63 per cent. of FeCl_3 . The solution obtained by dissolving 12·5 grammes in sufficient water to produce 50 millilitres complies with the tests for purity of *Liquor Ferri Perchloridi*. Lead limit, 50 parts per million.

Action and Uses.—Ferric chloride has the general properties of iron salts, and is powerfully astringent. It is usually **administered** as *Liquor Ferri Perchloridi*, but the alcoholic solution (*Tinctura Ferri Perchloridi*) is often preferred. Ferric chloride acts as a powerful styptic when applied locally. As an astringent paint for the throat, a solution (1 in 8) in diluted glycerin is prepared; for use as a throat spray, an aqueous solution (1 in 60) is employed. The chloride is used in the preparation of styptic wool and styptic lint; they contain about 15 per cent. of ferric chloride. *Liquor Ferri Dialysati* is a non-irritating

hæmatinic without astringency, and is given where astringent salts of iron tend to derange the stomach. It should be prescribed undiluted, the dose being added to water at the time of taking; or it may be prescribed with two parts of glycerin, which forms a stable solution, sometimes known as *Glycerinum Ferri Dialysati*. It is an excellent antidote for poisoning by arsenic, being given for that purpose in doses of 30 millilitres (1 fluid ounce). *Liquor Ferri Oxychloridi* possesses a very mild astringency, and is much more stable than *Liquor Ferri Dialysati*. It is employed as a hæmatinic, and is best diluted with glycerin and water (1 part and 3 parts).

Liquor Ferri Perchloridi Fortis is employed chiefly in the preparation of the weaker solution and of the tincture. It is used locally as a styptic to arrest bleeding from small wounds. Mixed with 3 parts of glycerin it is used as a paint for the throat; on account of the acidity of this mixture, however, a solution of the solid ferric chloride in glycerin is often preferred. Iron perchloride is **incompatible** with alkalis, iodides, astringent infusions and mucilage of acacia.

Dose.—0·03 to 0·12 gramme ($\frac{1}{2}$ to 2 grains).

Preparations

Antidotum Arsenum, B.P.C.—(Antidot. Arsen.)—Arsenic Antidote. It contains freshly precipitated ferric hydroxide and light magnesium oxide. Dose.—120 millilitres (4 fluid ounces)

Glycerinum Ferri Perchloridi, B.P.C.—(Glycer. Ferr. Perchlor.)—Glycerin of Ferric Chloride. Solution of ferric chloride and glycerin, equal parts.

Liquor Ferri Dialysati, B.P.C.—(Liq. Ferr. Dialysat.)—Solution of Dialysed Iron. A colloidal solution containing the equivalent of from 3 to 4 per cent w/v. of Fe. Dose. 0·6 to 2 millilitres (10 to 30 minims).

Liquor Ferri Oxychloridi, B.P.C.—(Liq. Ferr. Oxychlor.)—Solution of Ferric Oxychloride. *Syn.*—Soluble Peroxide of Iron; Solution of Chloroxide of Iron; Solution of Basic Ferric Chloride. It contains the equivalent of about 3 per cent. w/v. of iron. Dose—0·6 to 2 millilitres (10 to 30 minims).

Liquor Ferri Perchloridi, B.P.—(Liq. Ferr. Perchlor.)—Solution of Ferric Chloride. An aqueous solution containing 15 per cent w/v of FeCl_3 (limits, 14·25 to 15·75), equivalent to about 5 per cent. w/v of metallic iron. Arsenic limit, 2·5 parts per million. It complies also with limit tests for copper and zinc, and sulphate. 1 millilitre contains 0·15 gramme of ferric chloride, corresponding to about 0·05 gramme of iron; 15 minims contains about $2\frac{1}{2}$ grains of ferric chloride, equivalent to about $\frac{1}{2}$ grain of iron. It may be prepared by diluting 1 volume of strong solution of ferric chloride with sufficient distilled water to produce 4 volumes. Dose.—0·3 to 1 millilitre (5 to 15 minims).

Liquor Ferri Perchloridi Fortis, B.P.C.—(Liq. Ferr. Perchlor. Fort.)—Strong Solution of Ferric Chloride. It contains from 58·5 to 61·5 per cent. w/v of FeCl_3 , corresponding to about 20 per cent. of Fe; it is four times the strength of *Liquor Ferri Perchloridi, B.P.*

This solution was included in the British Pharmacopæia, 1914.

Tinctura Ferri Perchloridi, B.P.C.—(Tinct. Ferr. Perchlor.)—Tincture of Ferric Chloride. It is of the same strength as solution of ferric chloride but contains 25 per cent. v/v of alcohol (90 per cent.). Dose.—0·3 to 1 millilitre (5 to 15 minims).

This tincture was included in the British Pharmacopæia, 1914.

FERRI PHOSPHAS**(Ferr. Phosph.)****Iron Phosphate**

Iron phosphate may be obtained by the interaction of ferrous sulphate, sodium phosphate and sodium bicarbonate in aqueous solution. It consists of a mixture of hydrated ferrous phosphate and ferric phosphate, and some hydrated oxides of iron. It occurs as a slate-blue, amorphous powder, which is liable to darken in colour on exposure to air owing to oxidation and should be **stored** in well-closed containers.

Insoluble in water; readily soluble in hydrochloric acid.

Standard.—Iron phosphate, determined by the method of the British Pharmacopœia for Ferri Carbonas Saccharatus, contains not less than 47 per cent. of ferrous salts, calculated as ferrous phosphate, $\text{Fe}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$; each millilitre of N/10 potassium dichromate is equivalent to 0.01672 gramme of $\text{Fe}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$. Arsenic limit, 5 parts per million.

Action and Uses.—Iron phosphate is a mild ferruginous salt, with only slight astringent properties, and is used in rickets, the anæmias of children, tuberculous disease and neurasthenic conditions. It is **administered** in the form of Syrupus Ferri Phosphatis, Syrupus Ferri Phosphatis Compositus and Syrupus Ferri Phosphatis cum Quinina et Strychnina. Syrupus Ferri Phosphatis cum Quinina et Strychnina is incompatible with Syrupus Ferri Iodidi. Iron phosphate may also be dispensed in cachets, pills, or tablets.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

Preparations

Liquor Ferri Phosphatis, B.P.C.—(Liq. Ferr. Phosph.)—Solution of Ferrous Phosphate. It contains iron equivalent to from 14.1 to 14.7 per cent. w/v of $\text{Fe}_3(\text{PO}_4)_2$. Dose.—0.25 to 0.5 millilitre (4 to 8 minims).

Liquor Ferri Phosphatis Compositus, B.P.C.—(Liq. Ferr. Phosph. Co.)—Compound Solution of Ferrous Phosphate. It contains from 3.5 to 3.7 per cent. w/v of Fe, calculated as $\text{Fe}_3(\text{PO}_4)_2$, and from 5.4 to 5.8 per cent. w/v of calcium, calculated as $\text{Ca}_3(\text{PO}_4)_2$. When diluted with three times its volume of syrup it yields a compound syrup similar to that of the British Pharmacopœia. Dose.—0.5 to 2 millilitres (8 to 30 minims).

Pilule Ferri Phosphatis cum Quinina et Strychnina, B.P.C.—(Pil. Ferr. Phosph. c. Quin. et Strych.)—Iron Phosphate Pills with Quinine and Strychnine. *Syn.*—Pilule Trium Phosphatum; Easton's Pills; Pilule Ferri et Quininae et Strychninae Phosphatum. Each pill contains $1\frac{1}{8}$ grains of saccharated iron phosphate, about $\frac{1}{4}$ grain of quinine sulphate and $\frac{1}{10}$ grain of strychnine hydrochloride, and is approximately equivalent to $\frac{1}{2}$ fluid drachm of syrup of ferrous phosphate with quinine and strychnine. Dose.—1 or 2 pills.

Syrupus Ferri Phosphatis, B.P.C.—(Syr. Ferr. Phosph.)—Syrup of Ferrous Phosphate. It contains iron equivalent to from 1.7 to 1.9 per cent. w/v of $\text{Fe}_3(\text{PO}_4)_2$; 4 millilitres contains about 0.072 gramme, and 1 fluid drachm contains 1 grain, of anhydrous ferrous phosphate. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This syrup, prepared directly from iron, 0.86 per cent. w/v, phosphoric acid (specific gravity, 1.5), 6.25 per cent. w/v, syrup, 70 per cent. v/v, and distilled water, was included in the British Pharmacopœia, 1914.

Syrupus Ferri Phosphatis Compositus, B.P.—(Syr. Ferr. Phosph. Co.)—Compound Syrup of Ferrous Phosphate. *Syn.*—Parrish's Food; Parrish's Syrup; Chemical Food. It contains iron equivalent to 0.9 per cent. w/v of anhydrous ferrous phosphate, $\text{Fe}_2(\text{PO}_4)_2$ (limits, 0.85 to 0.95), and calcium equivalent to 1.4 per cent. w/v of tricalcium phosphate, $\text{Ca}_3(\text{PO}_4)_2$ (limits 1.3 to 1.5), with potassium and sodium phosphates, cochineal, sucrose, triple orange-flower water and distilled water. 8 millilitres contains the equivalent of about 0.7 gramme of anhydrous ferrous phosphate or about 0.034 gramme of iron, and the equivalent of about 0.11 gramme of tricalcium phosphate; 2 fluid drachms contains the equivalent of about $1\frac{1}{2}$ grains of anhydrous ferrous phosphate or about $\frac{1}{2}$ grain of iron, and the equivalent of about $1\frac{1}{2}$ grains of tricalcium phosphate. It should be stored in well-filled bottles. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

This syrup was included in the British Pharmaceutical Codex, 1923.

Syrupus Ferri Phosphatis cum Quinina et Strychnina, B.P.—(Syr. Ferr. Phosph. c. Quinin. et Strych.)—Syrup of Ferrous Phosphate with Quinine and Strychnine. *Syn.*—Easton's Syrup. It contains iron equivalent to 1.8 per cent. w/v of anhydrous ferrous phosphate, $\text{Fe}_2(\text{PO}_4)_2$ (limits, 1.62 to 1.98), 1.09 per cent. w/v of anhydrous quinine (limits, 1.04 to 1.2), and 0.0246 per cent. w/v of strychnine (limits, 0.022 to 0.027), with syrup, glycerin and distilled water. 4 millilitres contains the equivalent of 0.072 gramme of anhydrous ferrous phosphate or about 0.034 gramme of iron, about 0.059 gramme of quinine sulphate, and about 0.0012 gramme of strychnine hydrochloride; 1 fluid drachm contains the equivalent of about 1 grain of anhydrous ferrous phosphate or about $\frac{1}{2}$ grain of iron, about $\frac{1}{2}$ grain of quinine sulphate and about $\frac{1}{10}$ grain of strychnine hydrochloride. The proportion of strychnine is approximately one half the proportion of strychnine contained in the corresponding preparation of the British Pharmacopœia, 1914. It should be stored in completely-filled, well-closed containers and protected from light. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Syrupus Triplex, B.P.C.—(Syr. Trip.)—Triple Syrup. Equal parts of compound syrup of ferrous phosphate, compound syrup of hypophosphites and syrup of ferrous phosphate with quinine and strychnine. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tabellæ Ferri Phosphatis cum Quinina et Strychnina, B.P.C.—(Tab. Ferr. Phosph. c. Quinin. et Strych.)—Tablets of Ferrous Phosphate with Quinine and Strychnine. *Syn.*—Tabellæ Trium Phosphatum; Easton's Tablets; Tabellæ Eastonii; Tabellæ Ferri et Quininæ et Strychninæ Phosphatum. Each tablet contains about $2\frac{1}{2}$ grains of saccharated iron phosphate, $\frac{1}{2}$ grain of quinine sulphate and about $\frac{1}{10}$ grain of strychnine hydrochloride, and is approximately equivalent to 1 fluid drachm of syrup of ferrous phosphate with quinine and strychnine. Dose.—1 tablet.

Tabellæ Phosphatum et Hypophosphitum Compositæ, B.P.C.—(Tab. Phosph. et Hypophosph. Co.)—Compound Tablets of Phosphates and Hypophosphites. *Syn.*—Triple Syrup Tablets. Each tablet contains saccharated iron phosphate, calcium, potassium and sodium phosphates, calcium, manganese, potassium and iron hypophosphites, strychnine and quinine sulphate, and is equivalent to 1 fluid drachm of a mixture of equal volumes of compound syrup of hypophosphites, compound syrup of ferrous phosphate and syrup of ferrous phosphate with quinine and strychnine. Dose.—1 tablet.

FERRI PHOSPHAS SACCHARATUS

(Ferr. Phosph. Sacch.)

Saccharated Iron Phosphate

Saccharated iron phosphate is prepared by dissolving 20 parts of fluid glucose in 400 parts of boiling distilled water, and dissolving 120

parts of ferrous sulphate in the solution. Sodium phosphate, 110 parts, is then dissolved in 400 parts of boiling distilled water, to which the solution of ferrous sulphate is added, stirring constantly. A solution of sodium carbonate (50 parts in 400 parts of boiling distilled water) is then added and mixed thoroughly. The supernatant liquid is decanted, the precipitate washed with two successive quantities, each of 2000 parts of boiling distilled water, then mixed with 20 parts of liquid glucose, dried at a temperature not exceeding 100° and reduced to a fine powder. The product contains hydrated ferrous phosphate, with ferric phosphate and some iron oxide. It occurs as a slate-blue powder. It should be **stored** in well-closed containers.

Partly **soluble** in water; soluble in hydrochloric acid.

Standard.—Saccharated iron phosphate, determined by the method of the British Pharmacopœia for Ferri Carbonas Saccharatus, contains not less than 60 per cent. of ferrous salts, calculated as ferrous phosphate, $\text{Fe}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$; each millilitre of N/10 potassium dichromate is equivalent to 0.01672 gramme of $\text{Fe}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$. Arsenic limit, 5 parts per million.

Action and Uses.—Saccharated iron phosphate is mildly ferruginous with only slightly astringent properties, and is used in the treatment of rickets, the anæmias of children, tuberculous disease and neurasthenic conditions. It may be dispensed in cachets, pills, or tablets.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

FERRI PYROPHOSPHAS SOLUBILIS

(Ferr. Pyrophosph. Solub.)

Soluble Iron Pyrophosphate

Synonyms—Soluble Ferric Pyrophosphate; Sodio-citro-ferric Pyrophosphate.

Soluble iron pyrophosphate may be prepared by dissolving sodium pyrophosphate in a strong solution of an equal weight of ferric citrate, or by dissolving ferric pyrophosphate in a strong solution of sodium citrate, evaporating the solution, at a temperature not exceeding 60°, to a thick syrup, spreading on glass plates and scaling. It occurs in apple-green, transparent scales, becoming dark and discoloured on exposure to light, without odour, and having an acidulous, slightly saline taste. A solution of the salt produces no precipitate with potassium ferrocyanide solution, unless the solution is acidified. When 0.1 gramme is fused with 0.1 gramme each of potassium nitrate and sodium carbonate, and the residue boiled with 10 millilitres of water and filtered, the filtrate, after being nearly neutralised with dilute nitric acid, yields a yellow precipitate with silver nitrate solution. It should be **stored** in well-stoppered, amber-coloured bottles. Similar compounds containing

potassium or ammonium in place of all or part of the sodium are prepared and have similar properties.

Freely and completely **soluble** in water; insoluble in alcohol.

Standard.—Soluble iron pyrophosphate contains not less than 10 per cent. of Fe. The filtrate obtained by dissolving 1 gramme in 10 millilitres of water, boiling with sodium hydroxide solution and filtering, on acidifying with hydrochloric acid, cooling, adding magnesium ammonio-sulphate solution and excess of solution of ammonia, produces a precipitate which, when collected, does not turn yellow on the addition of a few drops of silver nitrate solution (limit of phosphate).

Assay.—Dissolve 1 gramme, accurately weighed, in 14 millilitres of water, add 6 millilitres of hydrochloric acid and boil for fifteen seconds; cool, add 3 grammes potassium iodide and titrate the liberated iodine with N/10 sodium thiosulphate; each millilitre of N/10 sodium thiosulphate is equivalent to 0.005584 gramme of Fe.

Action and Uses.—Iron pyrophosphate has the general properties of iron salts. It may be administered in mixture form or in cachets. Solutions in water are fairly permanent and may be mixed with solutions of the hypophosphites, with extract of malt, or with cod-liver oil emulsion. A sterilised solution is suitable for hypodermic use, the daily dose being from 0.06 to 0.12 gramme (1 to 2 grains).

Dose.—0.12 to 0.5 gramme (2 to 8 grains).

FERRI PYROPHOSPHAS.—Iron pyrophosphate, $\text{Fe}_4(\text{P}_2\text{O}_7)_3$, may be prepared by the interaction of sodium pyrophosphate and ferric sulphate, and occurs as a white powder. It is affected by light and should be stored in well-stoppered, amber-coloured bottles. Insoluble in water; slightly soluble in water containing carbon dioxide in solution and readily soluble in alkali citrates, forming green solutions. When iron pyrophosphate is prescribed, the soluble form (Ferri Pyrophosphas Solubilis) is always required. Dose.—0.12 to 0.5 gramme (2 to 8 grains).

Preparations

Extractum Malti Ferratum, B.P.C.—(Ext. Malt. Ferrat.)—Ferrated Extract of Malt. It contains 1.5 per cent. of soluble iron pyrophosphate in extract of malt. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Mistura Ferri cum Malto, B.P.C.—(Mist. Ferr. c. Malt.)—Mixture of Iron with Malt. Each fluid drachm contains 3 grains of soluble iron pyrophosphate in distilled water and liquid extract of malt. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

FERRI, QUININÆ ET STRYCHNINÆ CITRAS

(Ferr. Quinin. et Strych. Cit.)

Iron, Quinine and Strychnine Citrate

Iron, quinine and strychnine citrate may be prepared in the same manner as iron and quinine citrate, but with the addition of 1 per cent. of strychnine. It occurs in thin, transparent, deliquescent, greenish or

golden-yellow scales which are intensely bitter and mildly ferruginous in taste.

Soluble in water (1 in 2).

Standard.—Iron, quinine and strychnine citrate contains not less than 14·5 and not more than 15·5 per cent. of anhydrous quinine, not less than 0·95 and not more than 1·05 per cent. of strychnine and, when determined by the method of the British Pharmacopœia for Ferri et Quininae Citras, not less than 12 and not more than 14 per cent. of Fe. Arsenic limit, 5 parts per million.

Assay.—For strychnine. Dissolve 2·5 grammes, weighed accurately, in 45 millilitres of water, add 10 millilitres of dilute solution of ammonia and completely extract the alkaloids by shaking with successive quantities of chloroform. Evaporate the chloroform, dry at 100°, weigh the residue of quinine and strychnine, and proceed by the British Pharmacopœia process for the determination of strychnine in Syrupus Ferri Phosphatis cum Quinina et Strychnina.

For quinine. Subtract the weight of the strychnine from the weight of the residue of quinine and strychnine.

Action and Uses.—Iron, quinine and strychnine citrate is used as a bitter ferruginous tonic in the same way as iron and quinine citrate. The two preparations are identical in appearance, and care should be taken in storing and distinguishing the strychnine compound. It may be **administered** in mixture form, in pills massed by means of alcohol, or in capsules.

Dose.—0·12 to 0·3 gramme (2 to 5 grains).

FERRI SULPHAS

(Ferr. Sulph.)

Ferrous Sulphate

Ferrous sulphate may be prepared by dissolving iron in dilute sulphuric acid and crystallising. If precipitated from a warm, concentrated, slightly acidified, aqueous solution by the addition of alcohol, it is obtained in a granular condition, in which form it is less prone to oxidation. It occurs as transparent, green crystals or as a pale, bluish-green, granular, crystalline powder, with an astringent, metallic taste. Ferrous sulphate loses six molecules of water at about 38°; at higher temperatures in air, basic sulphates are produced. It should be **stored** in well-closed containers. The names, green vitriol and green copperas, are sometimes used for crude ferrous sulphate.

Soluble in water (1 in 1·5); insoluble in alcohol (90 per cent.).

Standard, B.P.—Ferrous sulphate contains not less than 99 per cent. of $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$. Arsenic limit, 2 parts per million. It complies

also with a limit test for absence of oxysulphate and with limit tests for copper, lead and acidity.

Action and Uses.—Iron compounds are particularly indicated in those forms of anæmia which are associated with a low colour index—the so-called microcytic hypochromic anæmias. These include simple achlorhydric anæmia, chlorosis, anæmia resulting from hæmorrhage, simple anæmia of pregnancy and the nutritional anæmia of infancy. The normal iron content of the body is about 3 grammes and, in health, the iron present in the food is absorbed in small quantities from the duodenum and in smaller quantities from the jejunum; it passes into the blood and to the liver, where it is built up with proteins to form a complex organic body which is liberated, as required, for the production of hæmoglobin. In anæmias due to loss of blood, recovery occurs without the exhibition of any drug, but iron accelerates the cure. Iron has a tonic action in all chronic cachectic conditions, such as malaria, syphilis and tuberculosis; that is, it tends to improve impaired activities of the body. In any condition in which deficiency of hæmoglobin exists, as in cardiac or renal disease, iron is also indicated. It is not so valuable in the treatment of pernicious anæmia, but is occasionally of great use when combined with arsenic.

It is generally agreed that the ferrous salts are the most satisfactory of the iron preparations for effecting hæmoglobin formation, and next in value are the scale preparations and reduced iron, which are capable of yielding ferrous ions in solution; ferric salts are relatively ineffective. It has been estimated that during the successful cure of anæmia of moderate severity, the quantity of hæmoglobin formed daily is equivalent to from 20 to 50 milligrams of metallic iron. In order to permit the absorption of this amount, the dose of the soluble salts should be equivalent to at least 100 milligrams of iron, and that of the insoluble salts ten times as much. Large doses of iron are therefore often necessary to produce a satisfactory cure of the anæmia, but there is evidence that ferrous sulphate is effective in doses of 20 grains daily. Pill of iron carbonate is often given in doses of 45 to 60 grains daily. Small doses of salts of copper or manganese are often prescribed with iron preparations on the assumption that they act as catalysts for the production of hæmoglobin. When intolerance is shown to iron given by the mouth, the drug may be injected intramuscularly; suitable preparations are the green iron and ammonium citrate and *Injectio Ferri*, but relatively large doses are necessary (see *Ferri et Ammonii Citras Viridis*). **Externally**, iron salts are powerfully astringent and styptic, the perchloride being most commonly employed for these properties.

Ferrous sulphate is **administered** in solution, often with magnesium sulphate, quinine sulphate and dilute sulphuric acid, as a tonic to promote appetite and improve the general condition, and in the treatment of amenorrhœa and anæmia. Its unpleasant taste is best covered with chloroform or peppermint water. In pill form, ferrous sulphate is often combined with arsenic, extract of *nux vomica* or extract of *belladonna*;

aloes is usually added to counteract the tendency to cause constipation. Large doses of ferrous sulphate, 200 grains daily, are sometimes given in pill form, the exsiccated salt being used. Large doses given in solution irritate the stomach and may have an emetic action. Iron preparations are administered on a full stomach. Dilute solutions of ferrous sulphate (0.5 to 1 per cent.) are used for astringent urethral and vaginal injections; an ointment (2 per cent.) has been used for hæmorrhoids.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

Preparations

Liquor Ferri Persulphatis, B.P.C.—(Liq. Ferr. Persulph.)—Solution of Ferric Sulphate. An aqueous solution of ferric sulphate containing the equivalent of from 14 to 15 per cent. w/v of Fe.

This solution was included in the British Pharmacopœia, 1914.

Mistura Ferri Composita, B.P.C.—(Mist. Ferr. Co.)—Compound Iron Mixture. *Syn.*—Griffith's Mixture. Each fluid ounce contains ferrous carbonate, equivalent to about 3 grains of ferrous sulphate, with potassium carbonate, myrrh, acacia, liquid glucose, spirit of nutmeg and rose water. **Dose.**—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

This mixture was included in the British Pharmacopœia, 1914.

FERRI SULPHAS EXSICCATUS

(Ferr. Sulph. Exsic.)

Exsiccated Ferrous Sulphate

Exsiccated ferrous sulphate is ferrous sulphate from which part of the water of crystallisation has been removed by drying at 40°. It occurs as a greyish-white powder. It should be **stored** in well-closed containers.

It is slowly, but almost completely, **soluble** in freshly boiled and cooled water.

Standard, B.P.—Exsiccated ferrous sulphate contains not less than 80 per cent. of FeSO_4 . Arsenic limit, 4 parts per million. It also complies with a test for solubility in acidified water.

Action and Uses.—Exsiccated ferrous sulphate is especially suitable for the preparation of pills which are intended to dissolve slowly in the stomach. Such pills are best made with syrup of liquid glucose, a rather soft mass being prepared quickly and cut into pills before hardening occurs. It may be given in doses of up to 9 grains or more daily.

Dose.—0.03 to 0.2 gramme ($\frac{1}{2}$ to 3 grains).

Preparations

Pilula Aloes et Ferri, B.P.—(Pil. Aloes et Ferr.)—Pill of Aloes and Iron. Exsiccated ferrous sulphate, about 10 per cent., and aloes, about 20 per cent., with cinnamon, cardamom, ginger and syrup of liquid glucose. 0.5 gramme contains

about 0.05 gramme of exsiccated ferrous sulphate, corresponding to about 0.015 gramme of iron; 8 grains contains about $\frac{1}{4}$ grain of exsiccated ferrous sulphate, corresponding to about $\frac{1}{4}$ grain of iron. Dose.—0.25 to 0.5 gramme (4 to 8 grains).

Pilula Ferri Carbonatis, B.P.—(Pil. Ferr. Carb.)—Pill of Iron Carbonate. *Syn.*—Blaud's Pill; Pilula Ferri; Iron Pill. It is prepared with exsiccated ferrous sulphate, exsiccated sodium carbonate, tragacanth, acacia, liquid glucose and water, and contains not less than 20 per cent. of ferrous iron, calculated as FeCO_3 . 2 grammes contains about 0.2 gramme, and 30 grains about 3 grains of iron. Dose.—0.3 to 2 grammes (5 to 30 grains).

Pilulæ Ferri Carbonatis Compositæ, B.P.C.—(Pil. Ferr. Carb. Co.)—Compound Iron Carbonate Pills. *Syn.*—Blaud's Pill with Aloin and Cascara. Each pill contains $\frac{1}{10}$ grain of aloin, $\frac{1}{2}$ grain of dry extract of cascara sagrada and 5 grains of pill of iron carbonate. Dose.—1 to 3 pills.

Pilulæ Ferri Carbonatis cum Arseno et Strychnina, B.P.C.—(Pil. Ferr. Carb. c. Arsen. et Strych.)—Pills of Iron Carbonate with Arsenic and Strychnine. *Syn.*—Blaud's Pills with Arsenic and Strychnine. Each pill contains $\frac{1}{100}$ grain of arsenic trioxide, $\frac{1}{100}$ grain of strychnine hydrochloride and 5 grains of pill of iron carbonate. Dose.—1 or 2 pills.

Pilulæ Ferri Carbonatis et Arseni, B.P.C.—(Pil. Ferr. Carb. et Arsen.)—Pills of Iron Carbonate and Arsenic. *Syn.*—Blaud's Pills with Arsenic. Each pill contains $\frac{1}{10}$ grain of arsenic trioxide and 5 grains of pill of iron carbonate. Dose.—1 pill.

Pilulæ Ferri et Arseni, B.P.C.—(Pil. Ferr. et Arsen.)—Iron and Arsenic Pills. *Syn.*—Pilulæ Ferri Arsenicales. Each pill contains 3 grains of exsiccated ferrous sulphate and $\frac{1}{10}$ grain of arsenic trioxide. Dose.—1 pill.

FERRI VALERIANAS

(Ferr. Valer.)

Iron Valerianate

Synonyms—Ferric Valerianate; Ferric Valerate.

Iron valerianate may be obtained by decomposing, in the cold, a solution of ferric sulphate or chloride with a solution of sodium valerianate, collecting the precipitate, washing with a little water, and drying at a temperature not exceeding 20°. It occurs as a dark red or brown, amorphous powder, having a slight odour and taste of valerianic acid.

Insoluble in water; entirely and readily soluble in alcohol; it is decomposed by boiling water, ferric oxide ultimately remaining.

Standard.—Iron valerianate yields on ignition not less than 24 per cent. of residue. Arsenic limit, 5 parts per million.

Action and Uses.—Iron valerianate, which combines the properties of the valerianates and iron, is given in hysterical conditions. It is prescribed in pills, usually with quinine and zinc valerianates, as in *Pilulæ Ferri Valerianatis Compositæ*.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

Preparation

Pilulæ Ferri Valerianatis Compositæ, B.P.C.—(Pil. Ferr. Valer. Co.)—Compound Iron Valerianate Pills. *Syn.*—Pilulæ Trium Valerianatum. Each pill contains 1 grain each of the valerianates of iron, quinine and zinc. *Dose.*—1 or 2 pills.

FERRUM

(Ferr.)

Iron

Fe = 55·84

Iron is metallic iron in the form of fine, bright wire about 0·1 millimetre in diameter (No. 42 Standard Wire Gauge). It contains usually about 99·5 per cent. of Fe, with minute quantities of carbon, sulphur, silicon, phosphorus and arsenic, and has a specific gravity of 7·6 to 8·14.

Standard, B.P.—Arsenic limit, 200 parts per million.

Action and Uses.—The medicinal properties of preparations of iron are described under Ferri Sulphas. Iron wire is employed in the preparation of certain solutions, syrups and wines.

Preparations

Syrupus Ferri Bromidi, B.P.C.—(Syr. Ferr. Brom.)—Syrup of Ferrous Bromide. Each fluid drachm contains about $4\frac{1}{2}$ grains of ferrous bromide. *Dose.*—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Syrupus Ferri Bromidi cum Quinina, B.P.C.—(Syr. Ferr. Brom. c. Quinin.)—Syrup of Ferrous Bromide with Quinine. Quinine dihydrobromide, 2 per cent. w/v, with dilute hydrobromic acid and distilled water, in syrup of ferrous bromide; each fluid drachm contains about $1\frac{1}{10}$ grains of quinine dihydrobromide and 4 grains of ferrous bromide. *Dose.*—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Syrupus Ferri Bromidi cum Quinina et Strychnina, B.P.C.—(Syr. Ferr. Brom. c. Quinin. et Strych.)—Syrup of Ferrous Bromide with Quinine and Strychnine. Strychnine, about 0·03 per cent. w/v, and quinine dihydrobromide, 2 per cent. w/v, with dilute hydrobromic acid and distilled water in syrup of ferrous bromide; each fluid drachm contains about $\frac{1}{10}$ grain of strychnine, $1\frac{1}{10}$ grains of quinine dihydrobromide and 4 grains of ferrous bromide. *Dose.*—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Vinum Ferri, B.P.C.—(Vin. Ferr.)—Iron Wine. Sherry-type wine in which iron has been macerated until the liquid contains from 0·125 to 0·300 per cent. w/v of Fe. *Dose.*—4 to 16 millilitres (1 to 4 fluid drachms).

This wine, prepared with sherry, was included in the British Pharmacopæia, 1914.

FERRUM REDACTUM

(Ferr. Redact.)

Reduced Iron

Reduced iron is a mixture of metallic iron and ferric oxide, which

may be obtained by heating ferric oxide to dull redness in a porcelain or iron tube in a current of dry hydrogen until water vapour ceases to issue from the tube, which is allowed to cool slowly while hydrogen is still passed through it. Over-heating during manufacture produces a coarse preparation owing to agglomeration of the particles. Reduced iron occurs as a fine greyish-black powder, free from metallic lustre and gritty particles. It dissolves almost completely in dilute mineral acids, with evolution of hydrogen and formation of a solution of a ferrous salt, a slight residue of carbon and silicon usually remaining. Heated to redness in air, it glows strongly and is converted into ferroso-ferric oxide, Fe_3O_4 . It should be **stored** in well-closed containers.

Insoluble in water and alcohol.

Standard, B.P.—Reduced iron contains not less than 80 per cent. of metallic iron. Arsenic limit, 200 parts per million.

Action and Uses.—Reduced iron is administered in the treatment of anæmia due to a deficiency of hæmoglobin. It is less suitable in cases associated with achlorhydria. It may be given in cachets, lozenges, or pills. Reduced iron is best made into pills by adding powdered liquorice and massing with syrup of liquid glucose or glycerin of tragacanth. Pills prepared with vegetable extracts, such as gentian, hyoscyamus and taraxacum, frequently split, owing to the evolution of hydrogen by reaction between the metallic iron and acids present in the extracts. Large doses, up to 2 grammes ($\frac{1}{2}$ drachm), are sometimes prescribed.

Dose.—0·06 to 0·6 gramme (1 to 10 grains).

Preparation

Trochisci Ferri Redacti, B.P.C.—(Troch. Ferr. Redact.)—Reduced Iron Lozenges. Each lozenge contains 1 grain of reduced iron.

This lozenge, containing 0·06 gramme of reduced iron, was included in the British Pharmacopœia, 1914.

FICARIA

(Ficar.)

Pilewort

Synonym—Lesser Celandine.

Pilewort consists of the fresh herb, *Ranunculus Ficaria* Linn. (Fam. Ranunculaceæ), a common, spring-flowering, perennial herb, indigenous to Great Britain.

The stem is decumbent; the leaves are mostly radical, with stout petioles and cordate laminæ, and are glabrous with a crenate margin. The peduncles are stout, slightly longer than the radicle leaves, single-flowered and sometimes also bear one or two small leaves: the

flowers are bright yellow, glossy and about one inch in diameter, with eight to twelve petals and three sepals; at the base of each petal is a nectary covered with a small scale. The leaves are less acrid than those of other species of *Ranunculus* and after boiling are edible. Several of the roots enlarge to oblong club-shaped tubercles which are very acrid and bitter. Nothing definite is known about the constituents, but the fresh plant probably **contains** traces of an acrid principle resembling, or identical with, anemonin.

Action and Uses.—Pilewort is an old remedy for hæmorrhoids. It is used in the form of ointment and suppositories. The latter are prepared by melting together 4 parts of the ointment and 1 part of spermaceti, and dividing the mass into suppositories each weighing 4 or 6 grammes (1 to 1½ drachms).

Preparation

Unguentum Ficaræ, B.P.C.—(Ung. Ficar.)—Pilewort Ointment. Benzoinated lard in which pilewort, 30 per cent., has been digested.

FICUS

(Fic.)

Fig

Fig is the dried succulent syconus of *Ficus Carica* Linn. (Fam. Moraceæ), a tree indigenous to Western Asia and cultivated in most warm and temperate climates. When the fruits are ripe, they are collected and dried in the sun. The varieties are known in commerce as “natural,” “pulled” or “pressed” figs. “Natural” figs are those which are packed loose and retain to some extent their original shape. “Pulled” figs have been kneaded and pulled to make them supple. “Pressed” figs have been closely packed in boxes so that they are compressed into discs.

The fig is a soft, fleshy, brown or yellowish fruit of irregular shape, up to about 5 centimetres in length and breadth; the outer part is tough and the large central hollow is lined by numerous drupels, each with a stone about 0.5 millimetre long. Externally, the fruit is sometimes covered with a saccharine efflorescence; at the summit is a small opening surrounded by bracts and at the base is a short, stalk-like portion. The odour is pleasantly fruity and the taste sweet.

Fig **contains** about 50 per cent. of sugar (principally invert sugar, but also some sucrose). Small quantities of citric, acetic and malic acids are also present.

Action and Uses.—Fig is nutritious and demulcent, and is used medicinally for its mildly laxative action, in the form of confections and syrups, usually with senna and carminatives.

Preparations

Syrupus Ficorum, B.P.C.—(Syr. Fic.)—Syrup of Figs. A solution of sucrose in an aqueous decoction of fig. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Syrupus Ficorum Compositus, B.P.C.—(Syr. Fic. Co.)—Compound Syrup of Figs. *Syn.*—Syrupus Ficorum Aromaticus; Aromatic Syrup of Figs. Compound tincture of rhubarb, 1 in 20, liquid extract of senna, 1 in 10, and elixir of cascara sagrada, 1 in 20, in syrup of figs. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

FILIX MAS

(*Filix Mas*)

Male Fern

Synonym—Aspidium.

Male fern consists of the rhizome and frond-bases of *Dryopteris Filix-mas* (Linn.) Schott (Fam. Polypodiaceæ), a fern indigenous to Great Britain. It is collected late in the autumn, divested of its roots and dead portions and carefully dried, and is used within one year from the date of collection.

Male fern occurs in pieces from 7 to 15 centimetres or more in length and about 5 centimetres wide, oblique in direction and ending in a large bud showing circinate veneration. The rhizome proper is about 2 centimetres in diameter and is entirely covered with the hard, persistent, ascending, semi-cylindrical, dark brown bases of the fronds. Both rhizome and frond-bases, which show a phyllotaxis of 5 : 8, are densely covered withramenta. The bases of the fronds are green internally, and the rhizome is yellowish-green. The transversely cut surface shows, both in each frond base and in the rhizome, a circle of about 7 to 9 pale yellowish, vascular strands of various sizes. Male fern has a slight odour and a taste which is at first sweetish and astringent, becoming later, bitter and nauseous.

The diagnostic **microscopical** characters are the abundant cellulose parenchyma of the ground tissue, filled with small starch grains up to 18 microns in diameter and showing intercellular spaces into which project shortly-stalked, pear-shaped, glandular trichomes; the yellowish-brown, fibrous sclerenchyma of the hypodermis; the large, lignified, prismatic, scalariform tracheids with pointed ends, from the xylem of the stele; the two-celled marginal teeth of theramenta, which are devoid of glands except at the base, where there are usually two.

Male fern **contains** a yellow, amorphous substance of an acid nature, termed filmarone, to which the properties of male fern as a vermifuge are attributed. In solution, it slowly decomposes into filicic acid and aspidinol, both of which also occur preformed in the drug. Filicic acid is crystalline and melts at 213° to 215°; aspidinol crystallises in white needles melting at 143°, and is sparingly soluble in benzene and light

petroleum. Other constituents of the drug are albaspidin (melting-point, 148°), and flavaspidic acid which exists in two modifications, the α -form melting at 92° and the β -form melting at 156° ; filicitannic acid is also present. Filicin is the name given to an amorphous modification of filicic acid, said to be an anhydride, as well as to the ether-soluble product obtained in the assay of the extract.

Substitutes.—The lady fern, *Athyrium Filixfœmina* Roth., and the shield fern, *Dryopteris spinulosa* O. Kuntze, occur occasionally as substitutes. The former is distinguished by the presence of only two large, dumb-bell shaped, vascular strands in each frond-base and by the absence of internal glandular trichomes in the parenchyma of the rhizome and frond-bases. The rhizome of *D. spinulosa* very closely resembles that of the male fern; it may be distinguished by theramenta, which bear unicellular glandular trichomes on the margins. It contains albaspidin and yields an active extract.

Standard, B.P.—Male fern contains not more than 2 per cent. of foreign organic matter, and crystals of calcium oxalate are absent. Ash, not more than 6 per cent. Acid-insoluble ash, not more than 2 per cent.

Male fern, in powder (Pulvis Filicis : Pulv. Filic.), contains the constituents and possesses the diagnostic microscopical characters of Filix, and complies with the limits for ash and acid-insoluble ash of the unground drug.

Action and Uses.—Male fern is a tænicide and, although occasionally used in powder form, is generally employed as Extractum Filicis to expel tape-worm, to all varieties of which it is a direct poison. In very large doses it is a violent irritant, giving rise to acute gastro-enteritis. Cases are on record in which considerable absorption has taken place and blindness has followed. Extract of male fern is **administered** in mixture form or in capsules. It can be emulsified with one-sixth its volume of tincture of senega, an equal weight of powdered acacia, or half its weight of compound powder of tragacanth. The treatment is best commenced with 2 grammes (30 grain) doses of sodium bicarbonate, three or four times a day for seventy-two hours; the patient should have no solid food for two days, then from 16 to 24 grammes (4 to 6 drachms) of magnesium sulphate is given late at night; a few hours after purgation the extract should be given, followed in not less than four to five hours by a full dose of a saline purgative. Occasionally extract of male fern is used for removal of hook-worms. It is also used for the treatment of liver-fluke in sheep. In cases of **poisoning** by male fern, a mild saline purgative should be given, followed by demulcent drinks and stimulants; heat should be applied externally.

Dose.— 4 to 12 grammes (1 to 3 drachms).

Preparation

Extractum Filicis, B.P.—(Ext. Filic.)—Extract of Male Fern. *Syn.*—Extractum Filicis Liquidum; Liquid Extract of Male Fern; Oleoresina Aspidii. It is extracted with ether and adjusted, if necessary, with olive oil to contain 25 per cent. w/w of filicin (limits, 24 to 26). It should be stored in well-closed containers and thoroughly stirred before use. *Dose.*— 3 to 6 millilitres ($\frac{1}{2}$ to $1\frac{1}{2}$ fluid drachms).

FLUORESCEINUM SOLUBILE

(Fluoresc. Solub.)

Soluble Fluorescein

Soluble fluorescein is the di-sodium salt of fluorescein, which is obtained by fusing phthalic anhydride and resorcinol at about 200° in the presence of a trace of sulphuric acid. The solid mass is purified by extraction with water, and the fluorescein obtained from the residue by dissolving in caustic alkali and precipitating the filtered solution with acid. Soluble fluorescein occurs as an odourless and almost tasteless orange-red powder. The aqueous solution is red when viewed by transmitted light; by reflected light it exhibits a strong green fluorescence which is visible in extreme dilutions. The fluorescence is destroyed by the addition of acid, but reappears when the solution is again made alkaline. Filter-paper which has absorbed a few drops of a 1 in 200 solution of soluble fluorescein is dyed yellow; if the paper is exposed to bromine vapour for one minute and then to the vapour of ammonia, the colour changes to a deep pink. Soluble fluorescein may be distinguished from acriflavine by the absence of a precipitate on the addition of sodium salicylate solution to a 1 in 500 solution.

Soluble in water (1 in 1), alcohol (90 per cent.) (1 in 5).

Standard, B.P.—Soluble fluorescein loses, on drying at 105°, not more than 5 per cent. of its weight. It complies also with limit tests for zinc, sulphate and chloride.

Action and Uses.—Soluble fluorescein is employed as a diagnostic agent in ophthalmic practice for delineating corneal lesions, etc., and for the detection of minute foreign bodies in the eye. Guttæ Fluoresceinæ is used for this purpose; the solution does not stain the normal cornea, but ulcers or parts deprived of epithelium become green, and foreign bodies appear surrounded by a green ring.

Soluble fluorescein in 2 to 5 per cent. solution, with the addition of 2 per cent. of sodium bicarbonate and 0.5 per cent. of glycerin, is used for external application as a spray over areas to be exposed to X-rays in the treatment of malignant disease. Solutions of similar strength, with or without added sodium bicarbonate, are used for intravenous injection in doses of 20 millilitres (300 minims), or doses of 1 to 3 grammes (15 to 45 grains) are given orally in the form of powders or in capsules. Solutions for **injection** may be sterilised by tyndallisation at 70° for one hour on three successive days.

EOSINUM.—Eosin (Colour Index No. 768) is the sodium or potassium salt of tetrabromofluorescein. It is a reddish-brown powder which is soluble in water forming a red liquid with a green fluorescence. Ethyl eosin, or eosin, spirit-soluble (Colour Index No. 770), is the potassium salt of the ethyl ester of tetrabromofluorescein. Eosin, blue-shade (Colour Index No. 771) is the potassium or sodium salt of dibromo-dinitrofluorescein. Eosin is used as a colouring agent for solution-tablets.

Preparation

Guttæ Fluoresceinæ, B.P.C.—(Gutt. Fluoresc.)—Fluorescein Eye Drops. *Syn.*—**Liquor Fluoresceinæ.** Soluble fluorescein, 2 per cent. w/v, in sterilised water.

FÆNICULUM

(Fœnic.)

Fennel

Synonyms—Fœniculi Fructus; Fennel Fruit.

Fennel consists of the dried, ripe fruits of cultivated plants of *Fœniculum vulgare* Mill. (Fam. Umbelliferæ). The plant is indigenous to the countries bordering the Mediterranean Sea, but is cultivated in the South of France, Saxony and Russia.

The fruits are up to about 10 millimetres long and 4 millimetres wide, and are usually entire cremocarps, with the pedicels attached. The cremocarp is oblong, laterally compressed, greenish-brown or yellowish-brown, glabrous and crowned by a short, bifid stylopod. Each mericarp has five prominent, yellowish, primary ridges and, when cut transversely, shows in the pericarp 2 commissural vittæ, and 4 dorsal vittæ which occur between the primary ridges, through each of which there runs a vascular strand. The small embryo is embedded in the upper end of the abundant oily endosperm, which is not grooved on the commissural surface. The odour is aromatic and the taste aromatic and camphoraceous.

The diagnostic **microscopical** characters are the epidermis of the pericarp, composed of quadrangular to polygonal cells with an unstriated cuticle; the lignified and reticulate parenchyma of the mesocarp; the polygonal, thick-walled cells of the endosperm, containing fixed oil, aleurone grains and minute rosettes of calcium oxalate; the inner epidermis of the pericarp with cells frequently showing a parquetry arrangement; the brown vittæ; the absence of starch.

Fennel **contains** from 3 to 4 per cent. of volatile oil. It yields to cold water from about 22 to 27 per cent. of extractive. The acid-insoluble ash is about 1.5 per cent.

Varieties.—Saxon fennel fruits are about 8 to 10 millimetres in length; they yield a volatile oil of which over 20 per cent. may consist of fenchone. Russian, Galician and Rumanian fennel closely resemble each other; they are usually shorter than the Saxon variety and yield a volatile oil containing a slightly smaller proportion of fenchone.

Substitutes.—The French sweet fennel, or Roman fennel, yields only about 2 per cent. of oil, which is practically free from fenchone. French fennel resembles the Saxon in appearance, but has a decidedly sweet anise odour. Japanese fennel is small (3 to 4 millimetres in length) and has an odour intermediate between that of the French and Saxon varieties; the oil contains about 10 per cent. of fenchone. Indian fennel is 6 to 7 millimetres long and has yielded 0.72 to 1 per cent. of oil containing 6.7 per cent. of fenchone. French bitter fennel is darker in colour, scurfy in the furrows and has less prominent ridges. Exhausted or partially exhausted fennel is deficient in oil and therefore deficient in odour; it may often be distinguished by its darker colour.

Standard, B.P.—Fennel contains not more than 2 per cent. of foreign organic matter. Ash, not more than 12 per cent.

Fennel, in powder (*Pulvis Fœniculi* : *Pulv. Fœnic.*), contains the constituents and possesses the diagnostic microscopical characters of *Fœniculum*, and complies with the limit for ash of the unground drug.

Action and Uses.—By virtue of the volatile oil which it contains, fennel has aromatic and carminative properties. It is a constituent of compound liquorice powder and is used in this and other powders to allay their tendency to gripe. Fennel water is sometimes mixed with sodium bicarbonate and syrup, and the mixture given to infants for the relief of flatulence.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

Preparations

Aqua Fœniculi Concentrata, B.P.C.—(*Aq. Fœnic. Conc.*)—Concentrated Fennel Water. Oil of Fennel, 1 in 50. One part added to 39 parts of distilled water yields a preparation which is approximately equivalent in strength to distilled fennel water, but contains 1.5 per cent. v/v of alcohol (90 per cent.). Dose.—0.3 to 1 millilitre (5 to 15 minims).

Aqua Fœniculi Destillata, B.P.C.—(*Aq. Fœnic. Dest.*)—Distilled Fennel Water. Fennel, 1 in 10. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

This water was included in the British Pharmacopœia, 1914, under the name of Aqua Fœniculi.

FÆNUM-GRÆCUM

(*Fœnum-Græc.*)

Fœnugreek

Fœnugreek consists of the seeds obtained from *Trigonella Fœnum-græcum* Linn. (Fam. Leguminosæ), an annual herb largely cultivated in India, Egypt and Morocco. The seeds are contained in long, narrow, sickle-shaped pods from which they are separated, when ripe, by threshing. Fœnugreek is exported chiefly from Mogadore and Bombay.

The seeds are rhomboidal in outline, brownish-yellow in colour, about 5 to 7 millimetres long and 2 millimetres thick. On one of the narrow sides is a depression in which both hilum and micropyle are situated, and from which a deep furrow runs diagonally, dividing the radicle pocket from the remainder of the seed. The endosperm is horny and translucent; it surrounds the radicle and two yellowish accumbent cotyledons, and swells considerably in water. The odour is characteristic and the taste disagreeable.

The diagnostic **microscopical** characters are the palisade epidermis of the seed coat, the cells of which are about 5 times as long as they are wide, conical at the upper extremity and rounded at the base; the hour-glass cells of the sub-epidermal layer, having bar-like thickenings on the radial walls, giving them a basket-like appearance; the polygonal

cells of the endosperm containing mucilage; the cells of the cotyledons containing aleurone grains and fixed oil.

Fœnugreek **contains** mucilage, about 28 per cent. (in the endosperm), fixed oil, about 6 per cent., and proteins, about 22 per cent. It also contains the bases, trigonelline and choline, and a flavone pigment.

Standard.—Fœnugreek contains not more than 2 per cent. of foreign organic matter. Ash, not more than 5 per cent. Cold water extractive, not less than 30 per cent.

Fœnugreek, in powder (*Pulvis Fœnum-Græci*: *Pulv. Fœnum-Græc.*), contains the constituents and possesses the diagnostic microscopical characters of *Fœnum-Græcum*, and complies with the limits for ash and cold water extractive of the underground drug.

Action and Uses.—Fœnugreek is used in veterinary medicine, and occasionally in curry powders.

FORMAMOL

(*Formam.*)

Formamol

Synonym—Hexamethylenetetramine Anhydromethylenecitrate.

Formamol may be prepared by combining anhydromethylenecitric acid with hexamine. It occurs in the form of colourless crystals, or as a white, crystalline powder, having an acid taste. It is slowly decomposed by dilute acids, and more readily by alkalis, with liberation of formaldehyde.

Soluble in water (1 in 5); sparingly soluble in alcohol; nearly insoluble in ether.

Action and Uses.—Formamol is given in infections of the genito-urinary tract and gall-bladder. It acts in the same way as hexamine. It is best administered with acetates and citrates, and may be given in cachets or tablets, which should be swallowed with a large draught of water.

Dose.—0.5 to 1 gramme (8 to 15 grains).

FRANGULA

(*Frang.*)

Frangula

Synonyms—Alder Buckthorn Bark; Frangula Bark.

Frangula consists of the bark of the stem and branches of *Rhamnus Frangula* Linn. (Fam. *Rhamnaceæ*), a shrub widely distributed over

Europe. It is collected in the spring, and should mature for at least a year before being employed medicinally.

The bark varies considerably in appearance, according to the age of the branch or stem from which it has been taken. Young bark, which is to be preferred, occurs in single or double quills about 1 centimetre wide and of papery texture, with an outer surface of smooth, dark-purplish cork, bearing numerous transversely-elongated, whitish lenticels; when gently scraped, the crimson colour of the inner layers becomes evident. The inner surface is brown, finely striated longitudinally, and the fracture is short in the cork and cortex, and fibrous in the phloem. Older bark is rougher externally, thicker, and usually occurs in single quills or channelled pieces. The smoothed, transverse surface shows a narrow, crimson or purple cork and a yellowish-brown cortex and phloem. The colour of the powder is changed from greenish-yellow to a deep purple-red by solution of caustic potash. The bark is odourless, but has a sweetish or slightly bitter taste. **Microscopically**, the cells of the cork contain purplish-red contents; in the cortex are large cells filled with mucilage; in the phloem are numerous medullary rays 1 to 2 cells wide, and tangential groups of fibres, with prismatic crystals of calcium oxalate in files of cells forming a crystal sheath around each group; throughout are rosette-crystals of calcium oxalate and a few very small starch grains. Stone cells are absent.

Frangula **contains** the crystalline glycoside, frangulin, which on hydrolysis gives rhamnose and frangula-cmodin (1 : 6 : 8-trihydroxy-3-methylanthraquinone).

Substitutes.—The bark of *R. saxatilis* Jacq. contains a dull red, instead of crimson, colouring matter in the cork and has sclerenchymatous cells in the outer bark. The bark of *Alnus glutinosa* Medic. also exhibits sclerenchymatous cells.

Standard.—Frangula contains not more than 2 per cent. of foreign organic matter.

Action and Uses.—Frangula bark has properties similar to those of cascara sagrada. It is used as a mild purgative, principally in the form of a liquid extract.

FUCUS

(Fucus)

Bladderwrack

Synonyms—Seawrack; Kelpware.

Bladderwrack is the dried plant, *Fucus vesiculosus* Linn. (Fam. Fucaceæ), a seaweed very common on the coast of Great Britain. For medicinal use the plant is freshly gathered from the rocks on which it grows, and dried.

The drug consists of the nearly black, thin, flattened, branching thallus, which is about 18 millimetres wide and sometimes as much as 1 metre in

length. When quite dry it is hard and brittle, and becomes softer and cartilaginous when moist. It has an entire margin and bears air vesicles in pairs. Some of the branches terminate in thickened enlargements, in which the reproductive organs are situated. The odour is characteristic of seaweed, and the taste is saline, mucilaginous and mawkish.

Bladderwrack **contains** a gelatinous substance, algin, and mannitol. A small variable amount of iodine is present, which is said to exist in the seaweed in the form of an organic compound.

Substitutes.—*Fucus serratus* Linn. is also commonly found on the sea-shore; it may be distinguished from bladderwrack by its serrated margin and the absence of air vesicles. *Ascophyllum nodosum* (Linn.) le Jol. has single vesicles.

Action and Uses.—Bladderwrack, by virtue of its iodine content, influences the activity of the thyroid gland. It has been used to reduce certain types of obesity. Bladderwrack is **administered** in the form of Extractum Fuci and Extractum Fuci Liquidum. The solid extract is suitable for the preparation of pills; the liquid extract is used in mixture form, generally with alkali iodides and sometimes in combination with liquid extract of thyroid. A decoction of the fresh plant has been used **externally** as a liniment for joint affections.

Preparations

Extractum Fuci, B.P.C.—(Ext. Fuci)—Extract of Bladderwrack. A soft extract.
Dose - 0.2 to 0.6 gramme (3 to 10 grains)

Extractum Fuci Liquidum, B.P.C.—(Ext. Fuci Liq.)—Liquid Extract of Bladderwrack 1 in 1. Dose - 4 to 8 millilitres (1 to 2 fluid drachms).

GALANGA

(Galang.)

Galangal

Synonyms—East Indian Root; Lesser Galangal.

Galangal consists of the dried rhizome of *Alpinia officinarum* Hance (Fam. Zingiberaceæ), cultivated in the South-East of China and on the neighbouring island of Hainan, to which it is indigenous.

The rhizome occurs in hard, branching, nearly cylindrical pieces varying from 4 to 8 centimetres in length and from 10 to 20 millimetres in thickness, and of a reddish-brown colour. It is marked with the fine, light yellow annuli of the leaf-bases, which encircle it at intervals of from 3 to 10 millimetres. The fracture is hard and fibrous. The smoothed, transverse section is generally paler than the exterior and exhibits a stele, which occupies about one-third of the total diameter. In both cortex and stele, numerous, scattered, deep red, resin cells occur. The taste is pungent and spicy, and the odour is agreeable, recalling that of ginger.

Galangal **contains** from about 0.5 to 1.5 per cent. of volatile oil, to

which the aroma is due, a pungent oily body, galangol, and three tasteless, yellow, crystalline bodies, namely, kæmpferide (1:3-dihydroxy-4-methoxyflavanol), galangin and the monomethylether of galangin (dihydroxyflavanol). The drug yields to alcohol (90 per cent.) about 10 per cent. of extractive.

Substitutes.—The rhizome of *Alpinia Galanga* Willd., greater galangal, should not be confused with that of *A. officinarum*. The former is occasionally imported from Java and may be distinguished by its larger size, orange-brown cork and pale buff interior.

Standard.—Galangal contains not more than 2 per cent. of foreign organic matter. Acid-insoluble ash, not more than 3 per cent.

Galangal, in powder (Pulvis Galangæ : Pulv. Galang.), contains the constituents of Galanga, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Galangal is aromatic and carminative. It is used in the form of infusion or decoction (1 in 20) for flatulence and dyspepsia.

Dose.—1 to 2 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ drachm).

GALBANUM

(Galban.)

Galbanum

Galbanum is a gum-resin obtained from *Ferula galbaniflua* Boiss. and Buhse (Fam. Umbelliferae), and probably other species of *Ferula*, indigenous to Persia. A portion of the drug appears to be collected from the natural exudation of the stem, but the larger part is obtained by cutting off the stem at the base of the plant, allowing the exudate to harden and removing successive slices of the root at intervals.

Galbanum occurs in distinct tears, in small masses of agglutinated tears, or in lump form. The tears are rounded or irregular in shape, usually from 5 to 10 millimetres in diameter, yellowish-brown or orange-brown externally, with a rough and often dirty surface. The fracture is granular, the exposed surface being pale yellowish in colour and opaque, though sometimes translucent and bluish-green. The tears are readily softened by pressure between the finger and thumb. The odour is characteristic and not unpleasantly aromatic, but the taste is bitter and rather disagreeable. Lump galbanum consists of yellowish, bluish-green or brownish tears embedded in a brownish mass mixed with slices of the root and some foreign matter. When 0.2 gramme of galbanum is powdered with 2 grammes of sand, the mixture boiled with 5 millilitres of alcohol (90 per cent.) for one or two minutes and the cooled, filtered tincture added to 5 millilitres of alcohol (90 per cent.) mixed with 0.5 millilitre of solution of ammonia, a blue fluorescence is produced (presence of free umbelliferone).

Galbanum **contains** a volatile oil (about 5 to 20 per cent.), resin

(about 50 to 70 per cent.), gum (about 20 per cent.), moisture (from 1 to 10 per cent.) and mineral matter. The resin consists of umbelliferone combined with galbaresinotannol, together with traces of free umbelliferone. The volatile oil contains α - and β -pinene, myrcene, a ketone, $C_{10}H_{16}O$, cadinene and cadinol. The drug yields about 40 per cent. of substances insoluble in alcohol (90 per cent.).

Varieties—Levant galbanum yields a volatile oil which is lævorotatory. Persian galbanum is softer than the Levant variety, and contains the fruits and portions of the stalks of the plant; it has a more terebinthinate odour and yields a volatile oil which is dextrorotatory.

Standard.—Galbanum yields not more than 7 per cent. of ash.

Action and Uses.—Galbanum is employed as a stimulant expectorant in chronic bronchitis. It has been used externally in the form of plaster (Emplastrum Galbani) for inflammatory swellings. On account of its disagreeable taste and odour galbanum is administered in pill form, generally with asafetida, as *Pilulæ Galbani Compositæ*, a combination which is prescribed in some hysterical conditions.

Dose.—0.3 to 1 gramme (5 to 15 grains).

Preparation

Pilulæ Galbani Compositæ, B.P.C.—(Pil. Galban. Co.)—Compound Pills of Galbanum. *Syn.*—Compound Pills of Asafetida. Each pill contains 1 grain each of asafetida, galbanum and myrrh. Dose.—1 or 2 pills.

GALLA

(Gall.)

Gall

Synonyms—Galls; Nutgall; Aleppo Galls; Blue Galls; *Gallæ Ceruleæ*.

Gall consists of the excrescences on the twigs of *Quercus infectoria* Olivier (Fam. Fagaceæ) resulting from the stimulus given to the tissues of the young twig by the deposition of an egg of the gall-wasp, *Cynips gallæ tinctoriæ* Olivier (Fam. Cynipidæ). It is collected in Asiatic Turkey and brought to Aleppo, and is known in commerce as Aleppo, Turkey, or Levant galls.

The excrescences are nearly spherical, 12 to 18 millimetres in diameter and dark bluish-green or olive-green in colour; near the base they are smooth, but the upper portion is tuberculated. They are hard and heavy and sink in water; they gradually absorb water, becoming enlarged and softened. Internally, they are brownish-white and show a central cavity, which is surrounded by a hard layer and contains a larva or pupa of *Cynips gallæ tinctoriæ*. In some galls a channel is bored from the central cavity almost to the external surface, and in it may be a young imago. The drug is odourless and the taste astringent and subsequently somewhat sweet.

The diagnostic **microscopical** characters are the fairly numerous sclerenchymatous cells from the region surrounding the central cavity;

the lignin bodies and scanty starch grains from the region within the sclerenchyma; the abundant, thick-walled and pitted parenchyma, containing numerous flakes of tannin and both cluster and prismatic crystals of calcium oxalate; the presence of only a few small vessels.

Gall **contains** gallotannic acid, about 50 to 70 per cent. Small quantities of gallic acid (2 to 4 per cent.), ellagic acid, sugar, starch, inorganic matter (about 2 per cent.), moisture (about 10 per cent.), and a monobasic hydroxycarboxylic acid termed cyclogallipharic acid are also present.

Substitutes and Adulterants.—"White" galls are brownish or yellowish-brown externally and show a small, circular perforation from which the insect has escaped; they are somewhat lighter and are less esteemed than "blue" galls, although the content of gallotannic acid is about the same. English galls formed on *Quercus Robur* Linn. by *Cynips Kollari* are brown, smooth, globular and usually perforated; they float on water, in which they do not become softened or swollen; they contain about 15 to 20 per cent. of gallotannic acid. Chinese or Japanese galls are formed by *Aphis chinensis* Bell on *Rhus semialata* Murray (Fam. Anacardiaceæ) and contain about 70 per cent. of gallotannic acid. They are irregularly formed with large, conical projections, being from 3 to 7 centimetres long; they have a covering of thick, grey, velvety down, which masks their reddish-brown colour.

Action and Uses.—Gall is powerfully astringent owing to the large proportion of gallotannic acid it contains. Preparations of gall are usually applied externally, although Tinctura Gallæ is occasionally administered internally as an astringent. Unguentum Gallæ and Unguentum Gallæ cum Opio, are valuable astringents for use in painful hæmorrhoids. For similar use, suppositories are prepared containing 0.3 gramme (5 grains) of powdered gall, with or without 0.06 gramme (1 grain) of powdered opium, or 0.03 gramme ($\frac{1}{2}$ grain) of cocaine. Preparations of gall are **incompatible** with the salts of iron, lead, copper and silver.

Dose.—0.6 to 1.2 grammes (10 to 20 grains).

Preparations

Tinctura Gallæ, B.P.C.—(Tinct. Gall.)—Tincture of Gall. 1 in 8. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Unguentum Gallæ, B.P.C.—(Ung. Gall.)—Gall Ointment. Gall, 20 per cent., in benzoinated lard.

This ointment was included in the British Pharmacopœia, 1914.

Unguentum Gallæ cum Opio, B.P.C.—(Ung. Gall. c. Opio)—Gall and Opium Ointment. Syn.—Unguentum Gallæ Compositum. Powdered opium, 7.5 per cent., in gall ointment.

This ointment was included in the British Pharmacopœia, 1914.

GELATINUM

(Gelat.)

Gelatin

Gelatin is obtained by boiling animal tissues, such as skin, tendons, ligaments and bones, with water, skimming and straining the resulting

liquid, evaporating the solution at a low temperature and drying by exposure to the air. The crude gelatin thus obtained is highly coloured and odorous and is subjected to a process of purification. Gelatin does not pre-exist as such in the animal tissues, but is formed by the prolonged action of boiling water on collagen, which is the substance of which the white fibres of connective tissues are composed and is probably an anhydride of gelatin.

Gelatin occurs in colourless or pale yellowish, translucent sheets or shreds, with only a slight odour and taste. It is permanent in air when dry, but putrefies rapidly when moist or in solution. Gelatin which has been softened by immersion in cold water dissolves when the water is heated, forming a viscous liquid which sets to a jelly on cooling. This property is much less marked after prolonged heating of the solution and is quickly destroyed by heating to 140° in sealed tubes, the gelatin being altered to gelatose, paragelatose, or gelatones. The gelatinising power of different samples varies considerably, and it is, therefore, often desirable to use the same brand of gelatin for the same preparation. A very pure gelatin may be prepared by soaking the best grade of the commercial substance for several days in successive quantities of water, by which treatment saline and other soluble bodies are removed. The gelatin is then dissolved in hot water and filtered while hot into alcohol. The white, thready masses thus precipitated are re-dissolved in hot water, the precipitation in alcohol repeated and the product subsequently dried. Thus prepared, gelatin yields only about 0.6 per cent. of ash.

The solubility of gelatin in acetic acid distinguishes it from chondrin, a mixture of glutin and mucinoid substances obtained from hyaline cartilage by boiling with water and precipitating from the aqueous solution with acetic acid. An aqueous solution of gelatin yields no precipitate with acids, except tannic acid, is not affected by lead acetate, ferric chloride, nor by the majority of metallic salts which precipitate the proteins, but is precipitated by chlorine water or bromine water, mercuric chloride, platinic chloride and trinitrophenol. It is completely precipitated by saturation with ammonium sulphate, magnesium sulphate or zinc sulphate. When potassium dichromate is added to the hot aqueous solution, the jelly which forms on cooling becomes insoluble in warm water after exposure to light; formaldehyde renders gelatin hard and insoluble after drying. When used as an article of food, gelatin must contain not more than 2 parts of arsenic and 20 parts of lead per million and must be free from copper and zinc.

Soluble in hot water, a cold mixture of glycerin and water and acetic acid; insoluble in alcohol (90 per cent.), ether and chloroform.

Standard, B.P.--Gelatin in 2 per cent. w/v hot aqueous solution is odourless and sets to a transparent or translucent jelly on cooling. Ash, not more than 2 per cent. Sulphur dioxide limit, 1000 parts per million. It complies also with a test for limit of acidity.

Action and Uses.—Gelatin has been used as a nutrient, but its value for this purpose has been much exaggerated. Experiment has shown, however, that it is well utilised as a protein when given in conjunction with milk proteins. Gelatin is used internally, chiefly as a hæmostatic. Injected hypodermically, 1 or 2 per cent. w/v in physiological sodium chloride solution, it has been used to promote the formation of clot in aneurisms and to arrest hæmorrhage from the lungs or kidneys. Stronger solutions (5 per cent.) have been used by rectal injection for purpura and hæmoptysis. Solutions for **injection** may be prepared by dissolving the washed gelatin in sterilised distilled water, after which they should be sterilised by heating in an autoclave at 120° for thirty minutes, care being taken to ensure that the whole of the solution is maintained at that temperature for thirty minutes. Solutions of gelatin for rectal, subcutaneous, or local use must be sterilised with the most rigorous care, since tetanus has in some instances arisen from their use, and some specimens of gelatin contain tetanus spores.

Gelatin is largely used as a demulcent and emollient in the preparation of pastilles for the local application of medicaments to the throat. A similar basis containing a smaller proportion of gelatin is used in the preparation of pessaries and urethral bougies and to solidify glycerin for use as a suppository. A gelatin-glycerin basis is also used for the preparation of nasal bougies (see Buginaria). Tannin, owing to the facility with which it combines with gelatin, is better prescribed with oil of theobroma in bougies, suppositories and pessaries. Pastes of gelatin with glycerin, of the type of Unna's paste, are prepared containing zinc oxide, resorcinol, or other medicaments. Gelatin is used in the preparation of culture media for use in bacteriology; certain bacteria have the power of liquefying the jelly.

Gelatin capsules afford a suitable means of administering many disagreeable substances in a convenient and readily soluble form. When solution is required to take place only in the intestine, the capsules may be coated with keratin or dipped in solution of formaldehyde. Sinclair's glue is an adhesive preparation made by dissolving 50 parts of gluc, 2 parts of glycerin, 2 parts of calcium chloride and 1 part of thymol in 50 parts of water. It is used in place of adhesive plaster for affixing extension apparatus to limbs in cases of fracture or joint disease. The preparation is melted on the water-bath and painted on the skin, the extension straps are pressed firmly in while the glue is still soft, and a bandage is then applied. Sinclair's glue gives more secure fixation than adhesive plaster, especially if the patient is febrile. Further, it can be used in cases where adhesive plaster is ineffective, as, for instance, for fixing extension apparatus directly to the sole of the foot.

Preparation

Glycogelatinum, B.P.C.—(Glycogel.)—Glycogelatin. Gelatin, 1 in 5, with sucrose, citric acid and flavouring agents.

GELSEMINA

(Gelsemin.)

Gelsemine

Gelsemine is an alkaloid obtained from gelsemium. It occurs in white, microscopic crystals. It has a strongly alkaline reaction and is dextrorotatory in chloroform solution. With concentrated sulphuric acid it gives a yellowish, and with concentrated nitric acid, a green colouration. Sulphuric acid with an oxidising agent gives a violet colouration, which becomes green after some time. The pure alkaloid melts at 178° .

Soluble with difficulty in water, more easily in alcohol, very easily soluble in ether and chloroform.

Action and Uses.—Gelsemine has the same action as gelsemium. Applied to the eye, it produces dilatation of the pupil, lasting about two days, and causes some irritation. Its use as a mydriatic has been abandoned. It is used in the treatment of trigeminal neuralgia and is **administered** in pills, frequently in combination with butylchloral hydrate. In cases of **poisoning** the antidotes described under Gelsemium should be employed.

Dose.—0.0005 to 0.002 gramme ($\frac{1}{200}$ to $\frac{1}{50}$ grain).

GELSEMINÆ HYDROCHLORIDUM. — Gelsemine hydrochloride, $\text{C}_{20}\text{H}_{22}\text{O}_2\text{N}_2, \text{HCl}$, occurs in the form of prismatic crystals or as a white crystalline powder. It is soluble in water, but not readily soluble in alcohol. Dose.—0.0005 to 0.002 gramme ($\frac{1}{200}$ to $\frac{1}{50}$ grain).

GELSEMIUM

(Gelsem.)

Gelsemium

Synonyms—Gelsemii Radix; Yellow Jasmine Root.

Gelsemium consists of the dried rhizome and roots of *Gelsemium sempervirens* Ait. (Fam. Loganiaceæ), a climbing plant indigenous to the Southern United States, and obtained chiefly from Virginia, North and South Carolina, and Tennessee.

The rhizome usually occurs in straight, almost cylindrical pieces, 5 to 20 centimetres in length and 3 to 30 millimetres in thickness. Attached to the rhizome are frequently small fibrous or large roots and sometimes small portions of the slender aerial stems of a dark purplish colour. The rhizome externally is light yellowish-brown, longitudinally wrinkled, with purple, reticulated lines on the older pieces; internally, it is light brown or pale yellow. The drug is tough and the fracture

splintery. The smoothed, transverse surface exhibits a conspicuously radiate structure, narrow, yellowish xylem wedges with small vessels alternating with straight, whitish medullary rays. The centre of the rhizome is usually occupied by a small, disintegrated pith. The root closely resembles the rhizome, but is somewhat tortuous and of a uniform, light brown colour. The scraped or broken surface exhibits a marked blue fluorescence when exposed to ultra-violet light. The taste is slightly bitter and the odour faintly aromatic.

The diagnostic **microscopical** characters are the thin-walled cork cells; the small amount of cortical parenchyma, containing spheroidal starch grains up to 8 microns in diameter; the prisms of calcium oxalate, up to 30 microns long, found in the medullary rays of the phloem; the abundant xylem elements; the lignified cells of the xylem medullary rays, containing small starch grains; the occasional pericyclic fibres from the pieces of aerial stem.

Gelsemium **contains** the crystalline alkaloid, gelsemine, and the amorphous mixture of alkaloids usually called gelseminine. The latter has much the greater physiological activity. There are also present scopoletin (gelsemic acid) and pentatriacontane, emodinmonomethyl ether, ipuranol and a mixture of fatty acids. Gelsemium yields to alcohol (60 per cent.) about 16 per cent. of extractive.

Standard.—Gelsemium contains not more than 2 per cent. of foreign organic matter

Action and Uses.—Gelsemium paralyses the nerve centres first, and the motor nerve endings only after very large doses have been given. It should be used with care, since untoward symptoms sometimes result from comparatively small doses. Excessive doses cause giddiness, double vision, and loss of power, with slowing and subsequent cessation of respiration. Gelsemium is employed in migraine and neuralgia, especially neuralgia of the fifth nerve, and also in rheumatism and in ovarian and uterine pain. It is **administered** in the form of tincture, which may be given in mixture form with the bromides or with butylchloral hydrate. Extract of gelsemium is prescribed in pills, frequently with butylchloral hydrate. In cases of **poisoning** by gelsemium or its alkaloids, the stomach pump should be used or an emetic given, followed by a hypodermic injection of atropine and administration of stimulants, artificial respiration being employed if necessary.

Dose.—0.016 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

Preparations

Extractum Gelsemii, B.P.C.—(Ext. Gelsem.)—Extract of Gelsemium. A soft extract. Dose.—0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains).

Tinctura Gelsemii, B.P.C.—(Tinct. Gelsem.)—Tincture of Gelsemium, 1 in 10. Dose.—0.3 to 1 millilitre (5 to 15 minims).

This tincture was included in the British Pharmacopœia 1914.

GENTIANA

(Gentian.)

Gentian*Synonyms*—Gentianæ Radix; Gentian Root.

Gentian consists of the dried rhizome and root of *Gentiana lutea* Linn. (Fam. Gentianaceæ), a herbaceous perennial indigenous to Central Europe and Spain, and imported chiefly from Marseilles. The rhizome and root are collected in the autumn and dried. The fresh rhizome and root is yellowish-white internally, but becomes darker by slow drying, during which the characteristic odour of the drug is developed.

Gentian occurs in sub-cylindrical pieces, which may be entire or split longitudinally and may vary in length from about 15 to 20 or more centimetres and in thickness up to about 2.5 centimetres, occasionally reaching as much as 4 to 8 centimetres at the crown. The outer surface of both rhizome and root is yellowish-brown to dark brown; the root is longitudinally wrinkled and the rhizome, which is occasionally branched, frequently terminates in a bud and bears numerous, encircling leaf-scars, which appear as transverse annulations. When moist the drug is tough and flexible, but when dry it is brittle and breaks with a short fracture; the smoothed, transverse surface is reddish-yellow and shows a well-marked, dark cambium ring, separating a somewhat wide bark from a large parenchymatous xylem which shows no distinctly radiate structure. The odour is characteristic and the taste at first sweet and afterwards intensely bitter.

The diagnostic **microscopical** characters are the abundant, somewhat thick-walled parenchyma, containing small globules of oil and sometimes groups of minute needles of calcium oxalate, about 3 to 6 microns in length; small numbers of reticulate, annular and spiral vessels; groups of yellowish-brown cork cells; occasional small starch grains; the absence of stone cells and fibres.

Gentian **contains** the bitter principles, gentiin and gentiamarin. Gentiin is crystalline and glycosidal; gentiamarin is amorphous. In addition to these substances, gentian root also contains a yellow, crystalline phenol (gentisin or gentianic acid), and the trisaccharide, gentianose, together with pectin and oil.

Substitutes.—The roots of various other species of *Gentiana* are found in commerce. The most important are *G. purpurea* Linn. from Switzerland, *G. pannonica* Scop. from Austria and *G. punctata* Linn. from Austria. These are all smaller than the root of *G. lutea*, the root of *G. purpurea*, which most nearly resembles it, attaining only about half the size; the crown of this root has a peculiar, branched appearance due to the presence of the bases of several aerial stems covered below with scaly leaves. White gentian of Continental commerce is derived from *Laserpitium latifolium* Linn., that of English commerce possibly from *G. Burseri* Lapeyr. Highly fermented gentian root may yield to cold water as little as 13 per cent. of extractive.

Standard, B.P.—Gentian contains not more than 2 per cent. of

foreign organic matter. Water-soluble extractive, not less than 33 per cent. Ash, not more than 6 per cent.

Gentian, in powder (*Pulvis Gentianæ* : *Pulv. Gentian.*), contains the constituents and possesses the diagnostic microscopical characters of Gentiana, and complies with the limits for water-soluble extractive and ash of the unground drug.

Action and Uses.—Gentian is a bitter and is used to improve the appetite and to stimulate gastric secretion, which it does reflexly through the sense of taste, and is therefore most effective if given shortly before meals. It is usually **administered** in the form of infusion, compound infusion, or compound tincture. The compound infusion is a suitable vehicle for alkaline, or acid digestive tonics.

Dose.—0.6 to 2 grammes (10 to 30 grains).

AZADIRACHTA.—Indian azadirach, neem bark, or margosa bark, is the dried stem bark of *Melia Azadirachta* Linn. (Fam. Meliaceæ), a tree indigenous to India, Ceylon and the Malay Archipelago. The bark occurs in channelled, tough, fibrous pieces, attaining to as much as 10 millimetres in thickness. Externally, it has a brownish-grey colour, and a rough, scaly or fissured surface. Internally, it is yellowish, conspicuously laminated, and coarsely fibrous. The smoothed, transverse surface is minutely chequered; pale, narrow medullary rays and tangential bands of parenchyma alternate with darker groups of bast fibres. Under the microscope, the latter are seen to be surrounded by lignified parenchymatous cells. Indian azadirach contains a bitter, amorphous resin, a crystalline, bitter alkaloid (margosine), margosic acid, a crystalline substance, and tannin. It is employed in India and the Eastern Colonies as an equivalent of gentian or quassia and is administered usually in the form of tincture or infusion.

Preparations

Extractum Gentianæ, B.P.—(*Ext. Gent.*)—Extract of Gentian. A soft aqueous extract. Dose.—0.12 to 0.5 gramme (2 to 8 grains).

Infusum Gentianæ Compositum Concentratum, B.P.—(*Inf. Gent. Co. Conc.*)—Concentrated Compound Infusion of Gentian. Gentian and dried bitter-orange peel, about 1 in 10, and lemon peel, about 1 in 5, extracted with alcohol (25 per cent.). This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh compound infusion of gentian and differs also in containing a small proportion of alcohol. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

A concentrated infusion, prepared with dilute chloroform water, alcohol (90 per cent.) and tinctures of orange and lemon, was included in the British Pharmaceutical Codex, 1923.

Infusum Gentianæ Compositum Recens, B.P.—(*Inf. Gent. Co. Rec.*)—Fresh Compound Infusion of Gentian. Gentian and dried bitter-orange peel, 1 in 80, and lemon peel, 1 in 40. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Mistura Gentianæ Acida, B.P.C.—(*Mist. Gent. Acid.*)—Acid Gentian Mixture. Each fluid ounce contains 12 minims of dilute nitro-hydrochloric acid, with syrup of orange, compound infusion of gentian and chloroform water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Mistura Gentianæ Alkalina, B.P.C.—(*Mist. Gent. Alk.*)—Alkaline Gentian Mixture. *Syn.*—*Mistura Gentianæ cum Soda.* Each fluid ounce contains 15 grains of sodium bicarbonate and 5 grains of ammonium carbonate, with syrup of orange and compound infusion of gentian. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Tinctura Gentianæ Composita, B.P.—(Tinct. Gent. Co.)—Compound Tincture of Gentian. Gentian, 1 in 10, with dried bitter-orange peel and cardamom, prepared by maceration with alcohol (45 per cent.). Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

GLUCOSUM LIQUIDUM

(Glucos. Liq.)

Liquid Glucose

Synonym—Corn Syrup.

Liquid glucose consists of a mixture of dextrose, maltose, dextrin and water, and may be prepared by the hydrolysis of starch. The starch is treated with dilute sulphuric acid and steam is passed through the mixture, or the starch and dilute acid are treated with steam under pressure. The acid is neutralised with calcium carbonate and the solution decolourised and evaporated under reduced pressure. It occurs as a colourless or almost colourless, odourless, viscid syrup with a sweet taste. Liquid glucose undergoes direct fermentation, reduces Fehling's solution, and is decomposed by alkalis, becoming brown in colour. It also reduces ammoniacal silver nitrate and an alkaline solution of mercuric cyanide. It is dextrorotatory. Medicinal glucose or dextrose monohydrate, and commercial grades of solid glucose are referred to under Dextrosum.

Miscible with water in all proportions, forming a clear solution; partly soluble in alcohol (90 per cent.).

Standard, B.P.—Liquid glucose has a refractive index at 20° of not less than 1.490. Ash, after ignition with sulphuric acid followed by re-ignition with sulphuric acid, not more than 0.6 per cent. Arsenic limit, 2 parts per million. Lead limit, 2 parts per million. Sulphur dioxide limit, 450 parts per million. It complies also with a limit test for acidity.

Action and Uses.—Liquid glucose is used in place of dextrose for oral or rectal administration. It should not be used, however, for subcutaneous, intravenous, or intrathecal injection. Liquid glucose is also used as a pill excipient, either alone or in the form of Syrupus Glucosi Liquidi. It is specially suitable for use in preparing pills containing ferrous carbonate, since it tends to prevent oxidation of the ferrous salt.

Preparation

Syrupus Glucosi Liquidi, B.P.—(Syr. Glucos. Liq.)—Syrup of Liquid Glucose. *Syn.*—Syrupus Glucosi, Syrup of Glucose. Liquid glucose, 33.3 per cent. w/w, with syrup.

GLYCERINUM

(Glycer.)

Glycerin*Synonym*—Glycerol.

Glycerin, $\text{CH}_2\text{OH}\cdot\text{CHOH}\cdot\text{CH}_2\text{OH}$, is a trihydric alcohol obtained by the hydrolysis of fats and fixed oils by means of alkalis or superheated steam. It occurs as a clear, colourless, odourless, hygroscopic, syrupy liquid, with a sweet taste followed by a sensation of warmth. When exposed to a low temperature for some time, it solidifies to a mass of colourless crystals, melting at about 20° . When heated with potassium bisulphate it gives off irritating vapours of acrolein. When mixed with borax and introduced into a bunsen flame, the flame is tinged green. It should be **stored** in well-closed containers.

Miscible with water and alcohol (90 per cent.); insoluble in ether, chloroform and fixed oils.

Standard, B.P.—Glycerin has a specific gravity of 1.260 to 1.265 (corresponding to from 98 per cent. to 100 per cent. of $\text{C}_3\text{H}_8\text{O}_3$). Refractive index at 20° , 1.470 to 1.473. Ash, not more than 0.01 per cent. Arsenic limit, 4 parts per million. Lead limit, 1 part per million. It becomes not more than faintly yellow and not pink when strongly heated, and on further heating volatilises and burns with little or no charring, and with no odour of burnt sugar. The 10 per cent. w/v aqueous solution is neutral to litmus. It complies also with a test for absence of certain reducing substances, and with limit tests for readily carbonisable substances, fatty acids, iron and copper.

Action and Uses.—Given internally, glycerin is demulcent, laxative, antiseptic and, to some extent, nutritious. It is commonly employed as a sweetening agent in mixtures, especially with ferric chloride and preparations of cascara or cinchona; it renders galenical preparations of the latter drugs more miscible with water. Glycerin is also employed as an ingredient of cough linctuses. In the form of pastilles, prepared with a gelatin basis and flavoured with fruit pastes or essences, or medicated with astringents or antiseptics, it is the most commonly used emollient for the throat. Limited amounts of glycerin may be used in place of sugar to sweeten the food of diabetic patients. Applied **externally**, glycerin acts as an emollient, somewhat resembling the oils in its action, although more irritating. Applied undiluted to mucous membranes, glycerin takes up moisture from the mucous secretions and increases the penetrative action of any drugs held in solution. Injections of sterile glycerin, in quantities ranging from a few millilitres up to 200 millilitres, either into the uterine cavity or into the cervical canal, are used in the prevention and treatment of puerperal infection.

Diluted with one or two volumes of water or rose water, glycerin is

useful as an emollient to the skin; it is the basis of numerous toilet creams and jellies and, in the form of *Glycerinum Amyli*, it may be applied to chilblains and chapped hands, and in the treatment of eczema and prurigo. Administered per rectum, glycerin promotes peristalsis by reflex action, local irritation being caused by the absorption of moisture from the mucous surfaces. As an ingredient of *Cataplasma Kaolini*, it is used for the relief of local congestion and inflammation. It may also be applied on a tampon, often with ichthammol, for congestion of the cervix uteri. Glycerin may be **sterilised** by heating at 150° for one hour. It is largely used as a preservative, especially in solutions of digestive ferments and other gland secretions, in calf lymph and in "aqueous" or non-alcoholic tinctures.

Dose.—4 to 8 millilitres (1 to 2 drachms); 2 to 8 millilitres ($\frac{1}{2}$ to 2 drachms), by rectal injection

ETHER-ÆTHYLENEGLYCOLMONOÆTHYLICUS.—Ethyleneglycol monoethylether, $C_2H_5O \cdot CH_2 \cdot CH_2OH$, may be obtained by refluxing ethylene glycol with sodium hydroxide and diethyl sulphate. It occurs as a colourless, almost odourless, non-toxic liquid, with a specific gravity of 0.934 to 0.938, and a boiling-range of 128° to 137°; the pure substance boils at 134.8°. It is miscible with water and hydrocarbons and is used as a solvent in the manufacture of lacquers and varnishes

ETHER-DIÆTHYLENEGLYCOLMONOÆTHYLICUS.—Diethyleneglycol monoethylether, or hydroxyethoxyethyl ether, $C_2H_5O \cdot CH_2 \cdot CH_2 \cdot O \cdot CH_2 \cdot CH_2OH$, may be prepared by the action of ethylene oxide on the sodium compound of ethyleneglycol monoethylether. It occurs as a colourless, hygroscopic liquid miscible with water and having a specific gravity at 20° of 1.02 to 1.03 and a boiling-range of 180° to 200°. The pure substance boils at 198°. It is used in the manufacture of lacquers as a solvent for gums, resins and cellulose nitrate, and is also used in the preparation of certain textile soaps and in dye printing.

GLYCOL ÆTHYLENICUM.—Ethylene glycol, or glycol, $CH_2OH \cdot CH_2OH$, may be obtained by the hydrolysis of ethylene chlorhydrin, which is formed by direct combination of ethylene and chlorine in the presence of water. It is a colourless, odourless liquid, with a sweetish taste and properties intermediate between those of alcohol and glycerin. It is somewhat viscous, very hygroscopic, and miscible with water or alcohol. It has a specific gravity of about 1.116 to 1.118 and a boiling-point of about 197°. It is used occasionally as a solvent

TRIACETINUM.—Triacetin is glyceryl triacetate, $C_3H_5(OOC \cdot CH_3)_3$, and occurs as a colourless, non-hygroscopic liquid, with a specific gravity of about 1.16 and a boiling-point of about 258°. It is slightly soluble in water, immiscible with paraffin hydrocarbons but completely miscible with aromatic hydrocarbons. It is widely used as a plasticiser in the manufacture of lacquers and varnishes.

Preparations

Suppositorium Glycerini, B.P.—(Supp. Glycer.)—Suppository of Glycerin
It contains 70 per cent. w/w of glycerin

Suppositorium Glycerini Saponatum, B.P.C.—(Supp. Glycer. Sap.)—Glycerin Soap Suppository. Glycerin, about 90 per cent. w/w, with sodium stearate

GLYCYRRHIZA

(Glycyrrh.)

Liquorice*Synonyms*—Glycyrrhizæ Radix; Liquorice Root.

Liquorice consists of the root and subterranean stem, chiefly stolon, of various species of *Glycyrrhiza* (Fam. Leguminosæ), the more important being *G. glabra* Linn., *G. glabra* var. *glandulifera* (Waldst. et Kit.) Regel et Herder, and *G. glabra* var. *violacea* (Boiss.) Boiss. *G. glabra* is a tall, erect, herbaceous perennial, widely distributed over Southern Europe; it is cultivated to a small extent in England, but is imported chiefly from Sicily, Spain and Syria. Liquorice is used in either the peeled or unpeeled condition.

Liquorice occurs in nearly cylindrical pieces about 1 to 2 centimetres in diameter and up to about 1 metre in length; it is sometimes cut into lengths of about 10 to 12 centimetres. When unpeeled, the external surface is longitudinally wrinkled, covered with a reddish-brown or purplish-brown corky layer, and bears small, circular root-scars and, upon the pieces of stolon, occasional small, dark buds; the outer surface of the peeled drug is smooth, yellow and fibrous; the fracture is fibrous in the bark and splintery in the wood. The smoothed, transversely cut surface shows a distinct cambium line at a depth of about one-third of the radius, separating the yellowish-grey bark from the finely radiate yellow wood which extends to the centre except in pieces of stolon, the latter showing a small pith. The narrow xylem wedges are finely porous, and opposite each is a strand of phloem in which the groups of fibres are visible as a radial row of dark points. When the drug is moistened with sulphuric acid, 66 per cent. v/v, a yellow colouration develops. The drug has a faint, characteristic odour, and a sweet taste which is almost free from bitterness.

The diagnostic **microscopical** characters are the thick-walled, lignified fibres in groups of 10 to 50 from both phloem and xylem, often accompanied by rows of small, rectangular cells each containing a prism of calcium oxalate; the large vessels of the xylem, bearing closely arranged bordered pits; the numerous starch grains, mostly about 10 microns in diameter; in the unpeeled drug, the brownish, polygonal-tubular cork cells.

Liquorice **contains** glycyrrhizin, a sweet, white, crystalline powder, consisting of the calcium and potassium salts of glycyrrhizic acid. The acid forms colourless crystals, melting at about 205°; it imparts a sweet taste to water in a dilution of 1 to 20,000, and the quantity present has been variously estimated at from 2 to 7 per cent. On hydrolysis, the acid yields glycyrrhetic and glycuronic acids. The drug also contains dextrose, sucrose, starch (about 30 per cent.), proteins, fat, resin and pteragin (about 1 per cent.)

Varieties.—Russian liquorice is obtained from *G. glabra* var. *glandulifera* which grows abundantly in Southern Russia; it consists mainly of root and is usually imported in the peeled condition. The pieces are often much larger than those of

G. glabra and may be split longitudinally. The cork, when present, is somewhat purplish in colour and frequently scaly. The taste is sweet but has a slight bitterness. Persian liquorice is obtained from *G. glabra* var. *violacea* and is usually imported unpeeled; it resembles unpeeled Russian root in appearance. Anatolian and Syrian liquorice are derived from *G. glabra*; they are usually unpeeled, the pieces are sometimes of a very large size, up to as much as 8 centimetres in diameter. Manchurian liquorice, possibly from *G. uralensis* Fisch., has a pale chocolate-brown, readily exfoliated cork, a lacunous wood and conspicuously wavy medullary rays. It contains glycyrrhizin, but is practically free from sugars. Liquorice of Indian origin, derived from *G. glabra*, closely resembles that imported from Spain but is usually cut into lengths of about 10 centimetres.

Standard, B.P.—Liquorice yields not less than 20 per cent. of water-soluble extractive. Ash of the peeled drug, not more than 6 per cent.; of the unpeeled drug, not more than 10 per cent. Acid-insoluble ash, not more than 2.5 per cent.

Liquorice, in powder (*Pulvis Glycyrrhizæ* : *Pulv. Glycyrrh.*), is the powder of the peeled drug. It contains the constituents and possesses the diagnostic microscopical characters of *Glycyrrhiza*, and complies with the standard for the unground, peeled drug.

Action and Uses.—Liquorice is a demulcent and mild expectorant. A decoction of liquorice with linseed or althæa is a domestic remedy for cough and bronchitis. Powdered liquorice is used as a flavouring agent in *Pulvis Glycyrrhizæ Compositus*; for medicinal use the solid and liquid extracts are usually administered. *Extractum Glycyrrhizæ*, with sedatives and expectorants, enters into the composition of cough lozenges and pastilles. The liquid extract is used in cough mixtures and to disguise the taste of nauseous medicines, especially the alkali iodides, ammonium chloride, quinine, creosote and liquid extract of cascara. It should, however, be prescribed only in alkaline or neutral solution. Powdered liquorice is frequently used as an absorbent pill excipient.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

ABRI RADIX.—Abrus root, or Indian liquorice, is the root of *Abrus precatorius* Linn. (Fam. Leguminosæ). It has poisonous properties similar to those of the seeds and should not be used as a sweetening agent.

GLYCYRRHIZINUM AMMONIATUM.—Ammoniated glycyrrhizin is prepared from the aqueous extract of liquorice and occurs as a reddish-brown powder or in scales. It is sometimes used as a flavouring agent instead of the liquid extract.

Preparations

Extractum Glycyrrhizæ, B.P.—(*Ext. Glycyrrh.*)—Extract of Liquorice. A soft aqueous extract. Dose.—0.6 to 2 grammes (10 to 30 grains).

Extractum Glycyrrhizæ Liquidum, B.P.—(*Ext. Glycyrrh. Liq.*)—Liquid Extract of Liquorice. An aqueous extract adjusted to a specific gravity of 1.200 and preserved with alcohol. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Pulvis Glycyrrhizæ Compositus, B.P.—(*Pulv. Glycyrrh. Co.*)—Compound Powder of Liquorice. Peeled liquorice and senna leaf, of each 16 per cent., with fennel, sublimed sulphur and sucrose. Dose.—4 to 8 grammes (1 to 2 drachms).

Trochisci Glycyrrhizæ, B.P.C.—(*Troch. Glycyrrh.*)—Liquorice Lozenges. *Syn.*—Brompton Cough Lozenges. Each lozenge contains 3 grains of extract of liquorice and $\frac{1}{4}$ minim of oil of anise.

GOSSYPH CORTEX

(Gossyp. Cort.)

Cotton Root Bark*Synonym*—Gossypii Radicis Cortex.

Cotton root bark consists of the dried root bark of *Gossypium herbaceum* Linn. and of other cultivated species of *Gossypium* (Fam. Malvaceæ), perennial plants indigenous to India, and cultivated in India, Egypt and the United States of America.

The root bark occurs in thin, tough and fibrous strips, often channelled or quilled, up to 30 centimetres long, to which long, thin, tapering rootlets are attached at intervals. The outer surface is covered with rough, cinnamon-brown cork, longitudinally striated or wrinkled, easily separated and revealing a paler cortex; the inner surface is whitish, silky and finely striated longitudinally. The fracture is tough and fibrous. The smoothed, transverse section shows a phloem laminated from the presence of alternating layers of fibres and sieve tissue; the outer laminæ, when separated, exhibit on their surfaces minute brownish spots due to resin cells. The odour is distinct and the taste somewhat acid and astringent.

Cotton root bark **contains** a pale yellow or colourless acid resin, which is present to the extent of about 8 per cent., and becomes bright reddish-brown from absorption of oxygen. From an alcoholic extract of the bark, dihydroxybenzoic acid, salicylic acid and two substances of a phenolic nature have been separated, together with betaine, a fatty alcohol, phytosterol, ceryl alcohol and a mixture of fatty acids. The bark also contains a considerable amount of sugar.

Standard.—Cotton root bark contains not more than 5 per cent. of wood and other foreign organic matter. Acid-insoluble ash, not more than 2 per cent.

Cotton root bark, in powder (Pulvis Gossypii Corticis : Pulv. Gossyp. Cort.), contains the constituents of Gossypii Cortex, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Cotton root bark has been used as an emmenagogue in dysmenorrhœa and as an abortifacient. It is **administered** in the form of decoction, liquid extract and tincture.

Preparations

Decoctum Gossypii Corticis, B.P.C.—(Dec. Gossyp. Cort.)—Decoction of Cotton Root Bark. 1 in 5. Dose.—15 to 60 millilitres ($\frac{1}{2}$ to 2 fluid ounces).

This decoction was included in the British Pharmacopœia, 1914, under the name of Decoctum Gossypii Radicis Corticis.

Extractum Gossypii Corticis Liquidum, B.P.C.—(Ext. Gossyp. Cort. Liq.)—Liquid Extract of Cotton Root Bark. 1 in 1. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This liquid extract was included in the British Pharmacopœia, 1914, under the name of Extractum Gossypii Radicis Corticis Liquidum.

Tinctura Gossypii Corticis, B.P.C.—(Tinct. Gossyp. Cort.)—Tincture of Cotton Root Bark. 1 in 4. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

GRANATI FRUCTUS CORTEX

(Granat. Fruct. Cort.)

Pomegranate Rind

Pomegranate rind consists of the dried pericarp separated from the fruit of *Punica Granatum* Linn. (Fam. Punicaceæ), a shrub or small tree cultivated in the countries bordering the Mediterranean Sea.

The rind occurs in thin, curved, irregular pieces, some of which carry the lower part of, or the entire, five-toothed, woody, tubular calyx, which is about 10 to 15 millimetres in diameter and encloses the remains of the style and stigma; other pieces show the scar, about 5 millimetres in diameter, left by the stalk, or a piece of stalk may be attached. The rind is about 1·5 millimetres thick and is coriaceous or woody; the outer surface is granular and brownish-yellow or reddish in colour; the inner surface is marked with angular depressions made by the seeds and with ridges marking the positions of the disseminations. The rind is odourless and has an astringent taste.

Pomegranate rind **contains** about 28 per cent. of gallotannic acid, together with a yellow colouring matter, but the alkaloids which characterise the bark of the root and stem have not been detected in the rind. The ash is about 4 per cent.

Action and Uses.—Pomegranate rind is a powerful astringent. It may be **administered** in the form of decoction in the treatment of diarrhoea and dysentery and has been used as a douche in leucorrhœa.

Dose.—1 to 2 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ drachm).

GRANATI RADICIS CORTEX

(Granat. Rad. Cort.)

Pomegranate Root Bark

Synonyms—Granati Cortex; Granatum; Pomegranate.

Pomegranate root bark consists of the dried bark of the stem and root of *Punica Granatum* Linn. (Fam. Punicaceæ), a shrub or small tree cultivated in the countries bordering the Mediterranean Sea.

The root bark occurs in channelled or curved pieces and the stem bark in straighter and more regular pieces, varying usually from 5 to 10 centimetres in length and from 1 to 3 centimetres in width. The outer surface of the root bark is rough, dull earthy in appearance and often

exhibits conchoidal depressions where portions of the outer layer have exfoliated owing to the formation of cork. The outer surface of the stem bark is smoother, with shallow, longitudinal, corky furrows, but only a few conchoidal depressions, and it is marked with the minute dark apothecia of lichens. The inner surface of both barks is smooth and yellowish, often with brown patches. The fracture is short and granular, and the smoothed, transverse section is nearly white, with numerous, fine, tangential and radial lines. Pomegranate root bark has an astringent and slightly bitter taste.

The diagnostic **microscopical** characters are the occasional patches of lignified cork cells, strongly thickened on the inner walls; the very numerous cluster-crystals of calcium oxalate, arranged singly in the parallel, tangential rows of cells of the phloem parenchyma; the numerous, uniseriate, secondary medullary rays; the occasional, large, thick-walled stone-cells, occurring singly or in groups of 2 or 3; the small, scattered starch grains, about 2 to 8 microns wide; the absence of fibres.

Pomegranate root bark **contains** several volatile alkaloids of which pelletierine and pseudo-pelletierine (N-methylgranatnine) are present in greatest proportion. Pure pelletierine alkaloid is a colourless liquid which rapidly absorbs oxygen and becomes brown and resinous. The question whether it occurs in an optically active form in the plant is still undecided. The optically inactive base boils at $106^{\circ}/21$ mm. Pseudo-pelletierine is crystalline, melts at 48.5° and boils at 246° . Other alkaloids present in smaller quantities are *isopelletierine*, *methylisopelletierine* and α -N-methylpiperidyl-2-propane- β -one. The base known as methylpelletierine is perhaps identical with *methylisopelletierine*. The bark also contains about 22 per cent. of gallotannic acid. The total alkaloid present varies, in good samples, from 0.5 to 0.9 per cent., stem bark containing about 0.5 per cent. of alkaloids. The drug yields from 5 to 13 per cent. of ash.

Standard.—Pomegranate root bark contains not more than 2 per cent. of wood or other foreign organic matter.

Pomegranate root bark, in powder (*Pulvis Granati Radicis Corticis*; *Pulv. Granat. Rad. Cort.*), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—Pomegranate root bark is very astringent and unpleasant to the taste owing to the large quantity of tannin present. It is used in the form of decoction (1 in 5) to expel tape-worm, a dose of 60 millilitres (2 fluid ounces) being given every two hours for four doses. Pomegranate root bark is not purgative; its use as a vermifuge must, therefore, be preceded and followed by a brisk purge, such as castor oil. Poisonous symptoms from the absorption of pelletierine have occurred; these take the form of giddiness, confusion of thought, and great muscular weakness.

Dose.— 1 to 2 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ drachm).

GRINDELIA

(Grindel.)

Grindelia*Synonyms*—Grindelia Robusta; Gum Plant.

Grindelia consists of the dried leaves and flowering tops of *Grindelia camporum* Greene (Fam. Compositæ), a perennial herb growing in the plains to the south-west of the Rocky Mountains. The leaves and tops are collected when the plants are flowering and fruiting, and dried. It should be **stored** in a cool, dry place.

The stems are smooth, rounded, and yellow or rose-tinted. The leaves are pale green, 2 to 5 centimetres long, oblong or spatulate, with a serrate margin; they are rigid, brittle, sessile or amplexicaul, and have a glabrous, minutely dotted surface. The capitula are up to 2 centimetres in diameter, yellow, hard and resinous, with several rows of lanceolate-acuminate, imbricated, recurved bracts, within which is a single row of yellow, ligulate florets and a central group of tubular, disc florets, each of the ovaries or compressed fruits being bi-auriculate at the summit and crowned by a pappus, consisting of one or two stiff, thick bristles. All parts are more or less covered with resin, especially the capitula. The odour is slight and the taste balsamic.

The diagnostic **microscopical** characters are the isobilateral structure of the leaves; the multicellular, sessile, broadly ovoid, glandular trichomes, 45 to 100 microns in diameter, occurring in depressions in the epidermis, and containing minute calcium oxalate rosettes in the epithelial cells; the numerous, lignified, bast fibres and small vessels, and pollen grains characteristic of the Compositæ.

Grindelia **contains** amorphous resins (more than 20 per cent.). Other constituents are hentriacontane, a crystalline phytosterol, various glycerides, *l*-dextrose, tannin, colouring matter and a trace of volatile oil. It yields to alcohol (90 per cent.) about 20 to 25 per cent. of extractive.

Standard.—Grindelia contains not more than 10 per cent. of stem of a diameter greater than 2 millimetres or other foreign organic matter. Acid-insoluble ash, not more than 2 per cent.

Grindelia, in powder (Pulvis Grindeliæ : Pulv. Grindel.), contains the constituents and possesses the diagnostic microscopical characters of Grindelia, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—The action of grindelia probably depends upon the depression of sensory nerve endings. It is used in spasmodic asthma, whooping cough, bronchitis and hay fever. It is also employed in heart disease to slow and regulate the pulse, and has been used in cystitis and in catarrh of the urinary passages. It is **administered** in the form of liquid extract, the rather nauseous taste of which may be masked with chloroform or glycerin. A lotion made by diluting the liquid extract

(1 in 10) is used in the treatment of dermatitis caused by the poison ivy (*Rhus toxicodendron*).

Preparation

Extractum Grindeliæ Liquidum, B.P.C.—(Ext. Grindel. Liq.)—Liquid Extract of *Grindelia*. 1 in 1. Dose.—0·6 to 1·2 millilitres (10 to 20 minims).

This liquid extract was included in the British Pharmacopœia, 1914.

GUAIACI LIGNUM

(Guaiac. Lign.)

Guaiacum Wood

Synonym—Lignum Vitæ.

Guaiacum wood is the heartwood of *Guaiacum officinale* Linn. and of *G. sanctum* Linn. (Fam. Zygophyllaceæ), evergreen trees, the former indigenous to the West Indian Islands and the north coast of South America, the latter indigenous to South Florida and the Bahama Islands.

The heartwood is dull greenish-brown in colour, dense, and heavier than water. The freshly smoothed, transverse surface shows alternating, concentric, light and dark brown bands (spring and autumn wood), traversed by the fine lines of the numerous, closely arranged medullary rays. The wood splits unevenly longitudinally owing to the irregular course of the fibres. The drug, when warmed, has an aromatic odour, and the taste is slightly acid. Guaiacum wood frequently occurs in chips or turnings, the latter light brown, becoming green on exposure to light. The sap wood, which should not be present in appreciable quantity, is lighter, and pale yellowish-brown in colour.

The diagnostic **microscopical** characters are the numerous thick-walled, tortuous fibres; the medullary rays, which are one cell wide and from 4 to 6 cells high; the large vessels, and the brown resin present in the vessels and in the cells of the parenchyma and medullary rays; the prisms of calcium oxalate in the wood parenchyma.

Guaiacum wood **contains** from 18 to 25 per cent. of resin, consisting of guaiaretic, guaiaconic and guaiacic acids; to guaiaconic acid is due the blue colouration produced by oxidising agents. It also contains two bodies, guaiacsaponic acid and guaiacsaponin, as well as a substance resembling gutta percha, termed guaiaгутtin.

Action and Uses.—Guaiacum wood is not much used in medicine; it is an ingredient of Decoctum Sarsæ Compositum.

GUAIACI RESINA

(Guaiac. Res.)

Guaiacum Resin

Guaiacum resin may be obtained from the wood of *Guaiacum officinale* Linn. or of *G. sanctum* Linn. (Fam. Zygophyllaceæ) by

extraction with alcohol or by the purification of the crude resin which is obtained by heating the wood. Guaiacum resin should be **stored** in well-stoppered, amber-coloured bottles.

The resin occurs in rounded or ovoid tears, frequently covered with a dull green powder, or in large blocks, the latter being the usual form. It breaks easily, with a clear, glassy fracture, thin pieces being transparent and exhibiting a colour varying from yellowish-green to reddish-brown. The powder is grey, but becomes green on exposure to light and air. It has a slightly acrid taste and, when warmed, an aromatic odour. A solution in alcohol is coloured blue on the addition of ferric chloride solution.

Guaiacum resin **contains** the resin acids, α - and β -guaiaconic acids (about 70 per cent.), guaiaretic acid (about 11 per cent.) and a small proportion of guaiacic acid. It also contains guaiac β -resin (15 per cent.) and small quantities of guaiac-yellow, vanillin and guaiacsaponin. α -Guaiaconic acid is readily converted by oxidising agents (ferric chloride, ozone, hydrogen peroxide, chromic acid, etc.) into a deep blue substance termed guaiac-blue.

Soluble in alcohol, ether, chloroform, creosote, and in solutions of the alkalis and of chloral hydrate.

Standard.—Guaiacum resin leaves not more than 4 per cent. of ash. 1 gramme of the resin, in powder, shaken for five minutes with 5 millilitres of light petroleum yields a colourless filtrate which does not become green when shaken with an equal volume of dilute copper acetate solution (absence of colophony). Not more than 10 per cent. is insoluble in alcohol (90 per cent.).

Action and Uses.—Guaiacum resin is a mild laxative and diuretic. For its supposed action upon the mucous membrane of the throat, it is used in the form of lozenge and pastille. In acute tonsillitis it is given in powder or as *Mistura Guaiaci*. Guaiacum resin is employed in chronic rheumatism and gout; it sometimes relieves the pain and inflammation, and if taken between the attacks may lessen the tendency to recurrence. It is said to be of some service in dysmenorrhœa, 0.6 gramme (10 grains) being given three times daily. It can be administered in powder, cachets, or capsules. *Tinctura Guaiaci Ammoniata* is used in mixture form, and should be prescribed with mucilage of tragacanth (1 part in 8 parts of mixture) to suspend the resin. A freshly prepared tincture of guaiacum is employed with ozonic ether as a test for blood. Lozenges or cachets of guaiacum and sulphur are used in chronic rheumatism; *Confectio Guaiaci Composita* is a domestic remedy used for the same purpose.

Dose.—0.3 to 1 gramme (5 to 15 grains).

Preparations

Confectio Guaiaci Composita, B.P.C.—(Conf. Guaiac. Co.)—Compound Confection of Guaiacum. *Syn.*—Chelsea Pensioner. Guaiacum resin, 1 per cent., rhubarb, 2 per cent., and sublimed sulphur, 14.5 per cent., with potassium acid tartrate, nutmeg and purified honey. Dose.—4 to 8 grammes (1 to 2 drachms).

Mistura Guaiaci, B.P.C.—(Mist. Guaiac.)—Guaiacum Mixture. Each fluid ounce contains about 11 grains of guaiacum resin, with sucrose, tragacanth and cinnamon water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

This mixture was included in the British Pharmacopœia, 1914.

Tabellæ Guaiaci et Sulphuris, B.P.C.—(Tab. Guaiac. et Sulphur.)—Tablets of Guaiacum and Sulphur. Each tablet contains 3 grains of sublimed sulphur and 3 grains of guaiacum resin. Dose.—1 to 3 tablets.

Tinctura Guaiaci, B.P.C.—(Tinct. Guaiac.)—Tincture of Guaiacum. *Syn.*—Tincture of Guaiac. 1 in 5. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tinctura Guaiaci Ammoniata, B.P.C.—(Tinct. Guaiac. Ammon.)—Ammoniated Tincture of Guaiacum. Guaiacum resin, 1 in 5, strong solution of ammonia, about 1 in 13, with oil of nutmeg and oil of lemon. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopœia, 1914.

Trochisci Guaiaci Resinæ, B.P.C.—(Troch. Guaiac. Res.)—Guaiacum Resin Lozenges. Each lozenge contains 3 grains of guaiacum resin.

This lozenge, containing 0.2 gramme of guaiacum resin, was included in the British Pharmacopœia, 1914.

GUAIACOL

(Guaiacol)

Guaiacol

Guaiacol consists chiefly of the monomethylether of *o*-dihydroxybenzene, $C_6H_4(OCH_3)OH$, and may be obtained by fractional distillation of wood-tar creosote, or produced synthetically by heating a mixture of equimolecular proportions of catechol, potassium hydroxide and potassium methylsulphate in a closed vessel at 170° to 180° . It occurs as a colourless, oily, highly refractive liquid or as colourless crystals. It has a penetrating odour and a caustic taste. On the addition of a trace of ferric chloride to a saturated aqueous solution of guaiacol, a blue colour is produced which rapidly changes to brown, the solution becoming turbid. Guaiacol in liquid form may be distinguished from creosote by shaking with ten times its volume of sulphuric acid; the colour produced is yellow and not reddish-brown.

Soluble in water (1 in 80); miscible with alcohol (90 per cent.), ether and fixed and volatile oils.

Standard, B.P.—Guaiacol has a specific gravity (liquid form) of 1.116 to 1.125 and a melting-point (crystals) of about 28° . Not less than 95 per cent. distils between 200° and 210° . Residue when heated on a water-bath, not more than 0.1 per cent. It complies also with tests for the absence of organic impurities and hydrocarbons.

Action and Uses.—Guaiacol is an antiseptic and deodorant, and is used in place of creosote for internal administration in phthisis. It is better tolerated than creosote, but its action as an antiseptic is less powerful. It is less toxic, but a better antiseptic, than phenol. It is apt to irritate the gastric mucous membrane, and in large doses it depresses

the basal ganglia of the brain, and may, like acetanilide, cause collapse. Besides its antiseptic action on the alimentary canal, guaiacol is also antipyretic, the temperature being lowered in the same way as by phenacetin or sodium salicylate. Guaiacol appears in the urine as sulphonate and glycuronate, the latter reduces copper salts and may be mistaken for sugar; a small proportion is oxidised in the system.

Many esters of guaiacol are employed in medicine. These are usually tasteless, and they generally pass through the stomach unchanged, but are decomposed in the intestine with liberation of guaiacol. Guaiacol is commonly **administered** dissolved in oil and enclosed in gelatin capsules which may contain from 0.06 to 0.3 millilitre (1 to 5 minims), or more, in each. It may advantageously be given dissolved in cod-liver oil, either floating on water, as an emulsion, or in capsules. Pills of guaiacol are prepared with soap and powdered liquorice as excipients, in the same manner as creosote pills. It is also administered in combination with iodine as an iodised tincture of guaiacol.

Guaiacol is applied **externally**, diluted with oil or hydrous wool fat (1 in 5 to 1 in 10), to the skin over rheumatic joints, and in orchitis, tuberculosis, pneumonia, pleurisy and neuralgia. Dissolved in olive oil (5 per cent.), it is used as an intra-laryngeal injection in phthisis, as a throat paint and as a hypodermic injection. The hypodermic administration is said, however, to have no advantage over the oral method and may cause collapse.

Dose.—0.3 to 0.6 millilitre (5 to 10 minims).

GUAIACOLIS BENZOAS.—Guaiacol benzoate is a colourless, crystalline powder which is administered in cachets containing 0.2 to 0.6 gramme (3 to 10 grains) as an intestinal antiseptic.

GUAIACOLIS CINNAMAS.—Guaiacol cinnamate occurs as white crystals. It is administered in incipient phthisis in doses of 0.3 to 1 gramme (5 to 15 grains).

GUAIACOLIS VALERIANAS.—Guaiacol valerianate is a liquid administered in capsules containing 0.12 to 1 millilitre (2 to 15 minims) as an intestinal antiseptic.

Preparation

Nebula Guaiacolis et Mentholis, B.P.C.—(Neb. Guaiacol. et Menthol.)—Guaiacol and Menthol Spray. Guaiacol, 2 per cent. w/v, and menthol, 4 per cent. w/v, in light liquid paraffin.

GUAIACOLIS CARBONAS

(Guaiacol. Carb.)

Guaiacol Carbonate

Guaiacol carbonate, $(\text{CH}_3\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{O})_2\text{CO}$, is the carbonic ester of guaiacol, and may be obtained by passing carbonyl chloride slowly into guaiacol previously dissolved in sodium hydroxide solution, washing the

precipitate and crystallising from alcohol. It occurs as a white, crystalline powder, almost without taste and odour. The salt is decomposed by alcoholic potassium hydroxide solution, and guaiacol is liberated from the solution on the addition of excess of acid.

Soluble in alcohol (1 in 70); insoluble in water.

Standard.—Guaiacol carbonate melts between 85° and 88°. Ash, not more than 0.1 per cent. The saturated alcoholic solution is neutral to moistened litmus paper and on the addition of ferric chloride solution no bluish-green colour is produced (absence of free guaiacol). When dissolved in 20 parts of sulphuric acid, not more than a faint yellow colour is produced (limit of foreign organic matter).

Action and Uses.—Guaiacol carbonate is a non-irritating form in which to administer guaiacol in fermentative diarrhoea, typhoid fever and phthisis. It passes through the stomach unchanged, but liberates guaiacol in the intestine, where it is absorbed; its use in phthisis is due to the fact that it is an antiseptic and tends to diminish the amount of secondary infection. In rheumatoid arthritis, good results have followed its use in combination with potassium iodide.

Dose.—0.3 to 1 gramme (5 to 15 grains).

GUARANA

(Guaran.)

Guarana

Synonyms—Paullinia; Brazilian Cocoa.

Guarana is prepared from the seeds of *Paullinia Cupana* H.B. and K. (Fam. Sapindaceæ), a climbing plant indigenous to Brazil and Uruguay. The seeds, collected when ripe, are washed and roasted to loosen them from a papery shell, from which they are partially freed by heating; the kernels are crushed, made into a paste with water, and divided into masses of varying size which are dried in the sun or by the heat of a slow fire.

The drug usually occurs in hard, heavy, cylindrical pieces from 10 to 30 centimetres long and 25 to 40 millimetres thick. The outer surface is almost smooth and is chocolate-brown in colour; internally are pale, irregular fragments embedded in a dark reddish mass. It has a slightly bitter taste but no marked odour.

The diagnostic **microscopical** characters of guarana, which yields a reddish-brown powder, are the numerous, rounded or polygonal, parenchymatous cells filled with more or less gelatinised starch; the fragments of the dark brown epidermis of the seed, consisting of palisade cells which in surface view have wavy outlines; the parenchymatous cells, with beaded or coarsely pitted walls, of the inner portion of the seed coat.

Guarana **contains** from 3·5 to 5 per cent. of caffeine, catechutannic acid, starch, and a little fat.

Standard.—Guarana contains not less than 3·5 per cent. of caffeine, calculated as anhydrous.

Guarana, in powder (*Pulvis Guaranzæ* : *Pulv. Guaran.*), contains the constituents and possesses the diagnostic microscopical characters of Guarana, and complies with the standard for the unground drug.

Assay.—To 6 grammes, finely powdered, add 120 millilitres of chloroform, shake and, after allowing to stand five minutes, add 6 millilitres of dilute solution of ammonia, and shake the mixture continuously during one hour. Allow the mixture to stand over-night, again shake intermittently during thirty minutes, and allow to settle. Filter off 100 millilitres of the chloroform solution, equivalent to 5 grammes of the drug, and evaporate to dryness. Treat the residue with 10 millilitres of warm N/5 sulphuric acid, cool, filter into a separator, and wash the dish and filter with successive small portions of water. Make the solution alkaline with sodium hydroxide solution and extract the caffeine immediately by shaking with successive portions of chloroform, washing each portion with about 10 millilitres of water contained in a second separator. Evaporate the chloroform, dry at 100°, and weigh the residue of anhydrous caffeine.

Action and Uses.—Guarana is used for the same purposes as caffeine; it is especially employed for sick headache, and is sometimes used as an astringent in diarrhœa and dysentery. It may be **administered** in powder form in a cachet, or mixed with water to form a draught. Elixir of guarana is a pleasant liquid form of the drug; tincture of guarana is suitable for use in mixture form.

Dose.—0·6 to 4 grammes (10 to 60 grains).

Preparations

Elixir Guaranzæ, B.P.C.—(*Elix. Guaran.*)—Elixir of Guarana. Tincture of guarana, 4 in 5, with oil of cinnamon, syrup and alcohol (60 per cent.). Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Tinctura Guaranzæ, B.P.C.—(*Tinct. Guaran.*)—Tincture of Guarana. 1 in 4. Dose—4 to 8 millilitres (1 to 2 fluid drachms).

GUTTA PERCHA

(*Gutt. Perch.*)

Gutta Percha

Gutta percha consists of the dried, purified latex of *Paladium oblongifolium* Burck, *P. borneense* Burck, *Payena Leerii* Kurz, *P. Treubii* Burck and other species (Fam. Sapotacæ), large trees indigenous to the Malay Archipelago. The latex is commonly collected by felling the trees and cutting transverse or oblique channels in the bark,

in which it collects and coagulates. The crude product is kneaded under hot water and made into flattened cakes, which are further purified by rolling, shredding and kneading.

Gutta percha occurs in lumps or blocks of variable, but often large, size; externally, it is of a brown or greyish-brown colour; internally, it is reddish-yellow or reddish-grey with a laminated or fibrous appearance. It has a characteristic odour and is flexible although only slightly elastic. It is partly soluble in benzene, oil of turpentine and carbon disulphide, and almost entirely soluble in chloroform.

Gutta percha **contains** the hydrocarbon gutta, $(C_5H_8)_n$, which, when pure, is white and minutely crystalline, a number of albanes, which are crystalline and soluble in boiling alcohol, fluavils, also crystalline but soluble in cold alcohol, and albanans, which are insoluble in alcohol. In addition to these substances, small quantities of tannin, salts and an unstable substance, guttan, are present.

Uses.—Gutta percha is used for the preparation of solution of gutta percha, which is employed as a substitute for collodion, and with which chrysarobin, resorcinol, and other medicaments may be incorporated for application to the skin. Spread in thin sheets, as gutta percha tissue, it is used as a covering for moist dressings and poultices to delay evaporation or to prevent soiling the linen. A prepared gutta percha is used as a temporary filling in dentistry.

Chicle, or chicle gum, is the dried latex of *Achras Sapota* Linn. (Fam. Sapotaceæ), indigenous to Mexico, Central America, and the north of South America. It occurs in large blocks varying in colour from grey to brick red, with darker spots and veins. The crude latex is washed and kneaded in hot water, yielding a product of a greyish-white colour. It has a granular, powdery fracture, but becomes plastic when worked between the fingers. When chewed, chicle should be almost tasteless and form a plastic mass which should not adhere to the teeth. The constituents of chicle are similar to those of gutta percha, but there is a larger proportion of resin and less gutta. Mixtures of varying proportions of rubber, resins and waxes occur in commerce under the name of chicle gum, but may be distinguished from genuine chicle by their tough and smooth texture. Chicle is used in the manufacture of chewing-gum.

Preparations

Liquor Gutta Percha, B.P.C.—(Liq. Gutt. Perch.)—Solution of Gutta Percha. *Syn.*—Traumaticin. Gutta percha, 10 per cent. w/w, in chloroform.

Tela Gutta Percha, B.P.C.—(Tel. Gutt. Perch.)—Gutta Percha Tissue. Gutta percha in thin sheets.

HÆMATOXYLUM

(Hæmatox.)

Logwood

Logwood is the unfermented heartwood of *Hæmatoxylon campechianum* Linn. (Fam. Leguminosæ), a tree indigenous to Central America, but naturalised in the West Indian Islands. The wood is exported as logs from which both the bark and sapwood have been

removed. Yucatan (Campeachy) logwood is considered the best; Jamaica logwood has less tinctorial power.

Logwood occurs in hard, compact, heavy logs or billets, dull orange to purplish-red externally, and reddish-brown internally; the smoothed, transverse surface shows narrow, closely set medullary rays and narrow, concentric, dark brown zones alternating with paler ones. The chips or coarser particles have a slight, agreeable odour and a sweet, astringent taste. When 0.1 gramme of very small chips is boiled with 5 millilitres of water and filtered, the filtrate on the addition of calcium hydroxide solution gives a purplish-blue colour.

The unfermented drug **contains** about 10 per cent. of a colourless, crystalline body, hæmatoxylin. Exposed to the air, hæmatoxylin gradually acquires a reddish colour. Its solution in ammonia, which is brownish-violet in colour, absorbs oxygen from the air, forming the ammonia compound of hæmatein from which the hæmatein can be obtained in crystals having a yellowish-green iridescence. It is this change that takes place during the fermentation of the chips. Logwood also contains tannin, resin and a trace of volatile oil.

Substitutes.—Fermented logwood chips are distinguished by their darker colour and the green lustre on portions of the surface, and usually contain from 10 to 20 per cent. of moisture. The fermentation of logwood is often avoided by the use of an oxidising mordant, such as potassium dichromate. Bastard logwood is of a very low quality and is apparently derived from a variety of *H. campechianum*.

Standard.—Logwood contains not more than 2 per cent. of foreign organic matter.

Action and Uses.—Logwood is used as a mild astringent in diarrhoea. It may be administered in the form of decoction or liquid extract. Preparations of logwood may colour the stools and urine red; they are **incompatible** with metallic salts, especially those of iron and mercury. Compound solutions of hæmatoxylin are used in histology to stain the nuclei of cells.

Preparations

Decoctum Hæmatoxyli, B.P.C.—(Dec. Hæmattox.)—Decoction of Logwood. Logwood, 1 in 20, and cinnamon, 1 in 100. Dose.—15 to 60 millilitres ($\frac{1}{2}$ to 2 fluid ounces).

This decoction was included in the British Pharmacopœia, 1914.

Extractum Hæmatoxyli Liquidum, B.P.C.—(Ext. Hæmattox. Liq.)—Liquid Extract of Logwood. *Syn.*—Liquid Extract of Hæmatoxylon. 1 in 1. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

HÆMOGLOBINUM

(Hæmoglob.)

Hæmoglobin

Hæmoglobin is the red colouring matter of blood. It may be obtained by adding to defibrinated blood ten times its volume of 3 per cent.

sodium chloride solution, allowing the mixture to stand for a day or two for the red corpuscles to subside, separating the clear liquid and shaking the deposit with water and an equal volume of ether; the aqueous layer is separated and cooled in ice, one quarter of its volume of alcohol is added and the mixture cooled to -5° , when the hæmoglobin crystallises out. The product obtained by this or by any similar process is the oxygen compound of hæmoglobin, known as oxyhæmoglobin. Hæmoglobin is a combination of the protein, globin, with the iron-containing, coloured compound, hæmatin ($C_{34}H_{30}O_4N_4Fe \cdot OH$). The separation of these two compounds can be effected with extreme ease and occurs when hæmoglobin is treated with weak alkalis, weak acids, or when heated above 70° . The hæmoglobins of different animals differ to a marked extent owing to variations in the nature of the globin group, but the hæmatin group is apparently constant in composition.

Pure hæmoglobin **contains** about 0.34 per cent. of iron, about 16 per cent. of nitrogen and 0.6 per cent. of sulphur. It has been shown that hæmoglobin always contains traces of copper, which appears to be essential for its formation in the body. In hæmocyanin, an analogous substance occurring in the blood of cephalopods, the iron is wholly replaced by copper. Hæmoglobin crystallises in plates, prisms or needles of the rhombic system, differing in form according to the animal from which it is obtained.

The material usually employed for pharmaceutical purposes is in the form of scales, powder, or paste of a dark reddish-brown colour, and should be readily and almost completely **soluble** in water. Hæmoglobin preponderates in venous blood, but in arterial blood is largely oxidised to oxyhæmoglobin. The combination of oxygen in oxyhæmoglobin is a very loose one and the oxygen may be removed by exposure in a vacuum. Hæmoglobin also readily combines with acetylene, and with carbon monoxide forming carboxyhæmoglobin which is a much more stable compound than oxyhæmoglobin. Owing to its stability, cases of coal-gas poisoning are generally fatal. When hæmoglobin with a trace of sodium chloride is heated with glacial acetic acid and cooled, crystals of hæmatin hydrochloride (hæmin) are formed. The crystals are of characteristic form and are used as a means of identifying blood stains. Hæmoglobin, oxyhæmoglobin and carboxyhæmoglobin can be identified by their absorption spectra.

Action and Uses.—Hæmoglobin has been used as a substitute for the salts of iron in the treatment of anæmia, especially of the secondary type, but it is generally conceded that it is distinctly inferior. Hæmoglobin is less irritant to the stomach than are the simple salts of the metal. It is converted to hæmatin in the stomach and then passes through the bowel, very little, if any, absorption taking place. Hæmoglobin may be **administered** in cachets, capsules, and tablets, or as Elixir Hæmoglobini.

Dose.—0.3 to 2 grammes (5 to 30 grains).

Preparations

Elixir Hæmoglobini, B.P.C.—(Elix. Hæmoglob.)—Elixir of Hæmoglobin. Hæmoglobin, 1 in 10, with glycerin, alcohol (90 per cent.), syrup, distilled water and vanillin. Dose 4 to 8 millilitres (1 to 2 fluid drachms).

Extractum Malti Liquidum cum Hæmoglobino, B.P.C.—(Ext. Malt. Liq. c. Hæmoglob.)—Liquid Extract of Malt with Hæmoglobin. *Syn.*—Malt and Hæmoglobin. Hæmoglobin, 1 in 8, in glycerin and liquid extract of malt. Dose. 4 to 16 millilitres (1 to 4 fluid drachms).

HAMAMELIDIS CORTEX

(Hamam. Cort.)

Hamamelis Bark

Synonym—Witch Hazel Bark.

Hamamelis bark is obtained from *Hamamelis virginiana* Linn. (Fam. Hamamelidaceæ), a shrub indigenous to the United States and Canada. The bark is collected in the spring and dried.

The bark occurs in thin, channelled or curved pieces, about 1.5 millimetres thick, up to 2 centimetres broad and 5 to 20 centimetres long. The outer surface is covered with a dull, smooth (or, in older pieces, scaly), grey cork marked with transverse lenticels, or, when the cork has been removed, with a smooth, pale reddish-brown cortex. The inner surface is pale reddish-pink, finely striated longitudinally, occasionally with small pieces of white wood adhering. The fracture of the cork and cortex is short and that of the phloem fibrous. The odour is slight and the taste astringent and slightly bitter. The smoothed, transverse surface exhibits a dark grey cork layer, a pale brown cortex, a narrow, dark brown layer of pericyclic sclerenchyma, and a wide, reddish-brown phloem. Solution of ferric chloride gives a bluish-black colouration with the powder or when applied to the transversely cut surface of the bark.

The diagnostic **microscopical** characters are the groups of fibres, accompanied by files of crystal cells containing prisms of calcium oxalate; the abundant stone cells, often unevenly thickened; the presence of only a few small, rounded starch grains; the absence of cluster-crystals of calcium oxalate.

Hamamelis bark **contains** about 6. per cent. of tannin, partly crystalline hamamelitannin, and partly amorphous. Gallic acid, resin, fat, a phytosterol and other bodies are also present. It yields to alcohol (45 per cent.) about 20 per cent. of extractive.

Standard.—Hamamelis bark contains not more than 2 per cent. of foreign organic matter.

Hamamelis bark, in powder (Pulvis Hamamelidis Corticis Pulv. Hamam. Cort.), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—Hamamelis bark is a local astringent and hæmodynamic. The tincture diluted with water is used as a lotion for small wounds, bruises and inflammatory swellings, and is applied externally or injected into the rectum in the treatment of piles.

Preparation

Tinctura Hamamelidis, B.P.C.—(Tinct. Hamam.)—Tincture of Hamamelis. 1 in 10. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopœia, 1914.

HAMAMELIS

(Hamam.)

Hamamelis

Synonyms—Hamamelidis Folia; Hamamelis Leaves; Witch Hazel Leaves.

Hamamelis consists of the dried leaves of *Hamamelis virginiana* Linn. (Fam. Hamamelidaceæ), a shrub indigenous to the United States and Canada. It is also used in the fresh condition.

The leaves are about 7 to 15 centimetres in length, brittle, dark green or brownish-green, broadly oval or rhomboid-ovate. The petiole is about 1 to 1.5 centimetres long; the margin is sinuate, the apex acute, the base cordate and unequal, the venation pinnate, and the lateral veins straight, running out to the margin, where each ends in a tooth, prominent on the under surface which bears numerous stellate hairs. The odour is not marked and the taste is bitter and astringent.

The diagnostic **microscopical** characters are the characteristic stellate hairs, consisting of 4 to 12 cells united at the base; the epidermal cells with wavy walls; the large, prismatic crystals of calcium oxalate in the endodermis; the large, lignified, slightly branched idioblasts.

Hamamelis **contains** tannin, gallic acid, a bitter principle and a trace of volatile oil.

Standard, B.P.—Hamamelis contains not more than 2 per cent. of foreign organic matter, and not more than 3 per cent. of stems.

Hamamelis, in powder (Pulvis Hamamelidis : Pulv. Hamam.), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—Hamamelis has properties similar to those of hamamelis bark. The liquid extract is used as a local astringent, diluted with 20 to 30 parts of water, and was formerly given internally in order to arrest hæmorrhage. Liquor Hamamelidis is used as a cooling lotion for bruises, as a lotion for piles, and, well diluted, as a constituent of eye lotions. Unguentum Hamamelidis is used as an astringent application to piles, and Extractum Hamamelidis, in the form of suppositories

containing 2 to 5 grammes, is also used; they may be combined with cocaine, extract of belladonna, zinc oxide, or bismuth subgallate.

Preparations

Extractum Hamamelidis, B.P.C.—(Ext. Hamam.)—Extract of Hamamelis.

Syn.—Hamamelin; Hamamelidin. A dry alcoholic extract. Dose.—0·06 to 0·3 gramme (1 to 5 grains).

Extractum Hamamelidis Liquidum, B.P.—(Ext. Hamam. Liq.)—Liquid

Extract of Hamamelis. 1 in 1. It is prepared from the dried leaves with alcohol (45 per cent.). Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Pasta Hamamelidis, B.P.C.—(Past. Hamam.)—Hamamelis Paste. *Syn.*—Witch

Hazel Cream. A non-greasy stearate cream containing about 50 per cent. w/v of solution of hamamelis.

Liquor Hamamelidis, B.P.C.—(Liq. Hamam.)—Solution of Hamamelis. *Syn.*—

Distilled Witch Hazel. A 1 in 1 solution prepared by distillation from the fresh leaf.

This solution was included in the British Pharmacopœia, 1914.

Suppositorium Hamamelini et Zinci Oxidi, B.P.C.—(Supp. Hamam. et Zinc.

Oxid.)—Hamamelin and Zinc Oxide Suppository. Each suppository weighs 30 grains (2 grammes) and contains 3 grains of extract of hamamelis and 10 grains of zinc oxide.

Unguentum Hamamelidis, B.P.C.—(Ung. Hamam.)—Hamamelis Ointment.

Liquid extract of hamamelis, 10 per cent., in wool fat and yellow soft paraffin.

This ointment, prepared with 60 per cent. of wool fat, and 30 per cent. of yellow soft paraffin, was included in the British Pharmacopœia, 1914.

HELLEBORUS

(Helleb.)

Hellebore

Synonyms—Black Hellebore; Helleborus Niger.

Hellebore consists of the rhizome and roots of *Helleborus niger* Linn. (Fam. Ranunculaceæ), a herbaceous perennial cultivated in England, but growing wild in abundance on the lower Alps of Central Europe.

The rhizome occurs in small, dark sepia-brown, very tortuous pieces, from about 2 to 6 centimetres in length and 4 to 8 millimetres in diameter. The upper surface of the rhizome shows cup-shaped scars, about 5 or 6 millimetres in diameter, of aerial stems and the under surface shows very numerous, circular root-scars and attached roots, about 1 to 2 millimetres thick, which are easily broken off and are finely wrinkled longitudinally. The smoothed, transverse surface of the rhizome exhibits a rather wide, brown cortex, a circle of about 3 to 10 wedge-shaped, paler xylem bundles, separated by well-marked medullary rays; in the centre is a small brown pith. The transverse surface of the root shows a wide cortex and a small, pale yellow stele occupying about one third of the

total diameter. The odour is slight and the taste bitter and acrid; the powdered drug is powerfully sternutatory.

The diagnostic **microscopical** characters are the abundant starch grains; the brown-walled cells of the tegumentary tissues; the spiral and reticulate vessels; the absence of crystals of calcium oxalate.

Hellebore **contains** two crystalline glycosides, helleborin and helleborein. It yields to alcohol (90 per cent.) from 30 to 40 per cent. of extractive.

Substitutes.—The rhizome of *H. viridis* Linn. cannot be distinguished from that of *H. niger* by any definite morphological characters; the rhizome of *H. foetidus* Linn. is stated to show little or no pith and the wood is more strongly developed. In addition to glycosides, both these rhizomes contain several alkaloids. Hellebore should not be confused with white hellebore, the rhizome of *Veratrum album* Linn., or with green hellebore, the rhizome of *Veratrum viride* Ait.

Action and Uses.—Hellebore is a powerful hydragogue cathartic and emmenagogue. It is poisonous in large doses, producing violent inflammation of the gastric and intestinal mucous membranes. Applied locally, the fresh root is violently irritant. Helleborin is a narcotic; helleborein, although a member of the digitalis group of glycosides, is not at all, or only very slightly, absorbed from the alimentary canal.

HEMIDESMUS

(*Hemides.*)

Hemidesmus

Synonym—Indian Sarsaparilla.

Hemidesmus is the dried root of *Hemidesmus indicus* R. Br. (Fam. Asclepiadaceæ), a climbing plant indigenous to India and Ceylon.

The root is tortuous, rigid, shrunken, and simple or only slightly branching. It occurs in pieces of varying length, usually from 10 to 30 centimetres, and from 3 to 6 millimetres thick. It varies in colour from dull red to dark brown, bears only a few wiry rootlets, and is marked at frequent intervals with encircling cracks that penetrate the cork and occasionally the bark. The thin layer of cork easily separates from the bark, and is in places detached from it. The wood is pale yellow and porous. Laticiferous cells are present in the phloem. The aerial stems, which are attached to the crown of the root, are slender and exhibit alternate leaf-scars. The odour recalls that of Tonka bean and the taste is aromatic and sweetish.

Hemidesmus **contains** a volatile, acidic principle which has not been fully investigated.

Action and Uses.—Hemidesmus is used in India in place of sarsaparilla. In the form of syrup, it is sometimes used as a flavouring agent.

HEXAMINA

(Hexamin.)

Hexamine*Synonyms*.—Methenamina; Hexamethylenetetramine.

Hexamine, $(\text{CH}_2)_6\text{N}_4$, may be prepared by the action of ammonia on formaldehyde. It occurs in colourless, odourless crystals or as a white, crystalline powder, with a taste which is sweetish at first but afterwards bitter. On heating, it sublimes at about 263° without melting, and with partial decomposition and evolution of a disagreeable odour. It burns readily with a blue, non-luminous flame. When warmed with acids, it is decomposed, with formation of the ammonium salt of the acid and evolution of formaldehyde. When a small quantity is mixed with an equal weight of salicylic acid and heated with sulphuric acid, a carmine-red colour is produced. The aqueous solution has an alkaline reaction and gives a precipitate with tannic acid and with mercuric chloride solution, the precipitate in the latter case becoming crystalline on standing.

Soluble in water (1 in 1.5) and alcohol (90 per cent.) (about 1 in 8).

Standard, B.P.—Hexamine contains not less than 99 per cent. of $\text{C}_6\text{H}_{12}\text{N}_4$. Ash, not more than 0.05 per cent. Arsenic limit, 2 parts per million. Lead limit, 2 parts per million.

Action and Uses.—Hexamine is employed as a disinfectant of the urinary system in the treatment of cystitis and urinary infections. Although belief in its supposed conversion into formaldehyde has been largely discredited, it is frequently prescribed after the urine has first been rendered acid by the administration of sodium acid phosphate. There is evidence that some formaldehyde is slowly evolved; the quantity may be insufficient to destroy the bacteria but is enough to inhibit their growth and thereby produce a beneficial effect on bacilluria. It has been used in the treatment of poliomyelitis and encephalitis lethargica since it is secreted into the cerebrospinal fluid. Hexamine is also excreted in the bile and on this account has been used with benefit in the treatment of cholecystitis. In these circumstances, doses as large as 6 grammes (90 grains) dissolved in water may be given thrice daily, after meals; at the same time 4 grammes (60 grains) of sodium bicarbonate and 4 grammes (60 grains) of potassium citrate are given in order to prevent irritation of the kidneys. Doses of 1 gramme (15 grains) of hexamine, given four times daily, are said to abort the common cold. It has also been recommended in various respiratory affections, such as acute rhinitis, acute bronchitis and whooping cough, because of its antiseptic effect when excreted by the saliva and bronchial mucous membrane.

Intravenous injections of hexamine have been reported to be of value in pneumonia, typhoid fever, post-operative anuria, cholecystitis, dysuria and cystitis. The usual dose by intravenous injection is 5 millilitres

(75 minims) of a 40 per cent. w/v solution, repeated twice or thrice in twenty-four hours. Solutions for **injection** may be sterilised by filtration. When administered orally, hexamine should be taken with a large volume of water and may be prescribed in solution flavoured with syrup of orange. In cystitis, it is frequently given with methylene blue in tablets, or, in the treatment of gonorrhœa, with sandalwood oil in capsules. When ignited, hexamine burns with a smokeless flame and generates an intense heat. A 5 grain tablet will burn with evolution of sufficient heat to boil 4 or 5 millilitres of water and can also be used to sterilise hypodermic needles, probes, etc., by flaming.

Dose.—0.6 to 2 grammes (10 to 30 grains)

HEXYL-RESORCINOL

(Hexyl-resorcin.)

Hexyl-resorcinol

Hexyl-resorcinol is 4-*n*-hexylresorcinol and may be prepared by condensing hexoic acid with resorcinol by means of zinc chloride, and reducing the hexoyl-resorcinol so formed with aluminium amalgam in alcoholic hydrochloric acid. It forms white needles or a fine, white, crystalline powder, having a pungent odour and a sharp astringent taste. A green colour is produced when a trace of ferric chloride solution is added to an alcoholic solution.

Slightly **soluble** in water (1 in 2000), readily soluble in alcohol, ether and glycerin; very slightly soluble in light petroleum.

Standard.—Hexyl-resorcinol does not melt below 66° Ash, not more than 0.1 per cent

Action and Uses.—Hexyl-resorcinol is a bactericide used especially as a genito-urinary antiseptic. It is suitable for **internal** administration and is non-toxic in therapeutic doses, non-irritating to the urinary tract, and is active in both acid and alkaline urine. Hexyl-resorcinol appears to be more particularly effective when the infecting agents are in the nature of gram-positive organisms, such as staphylococci or streptococci, and less so in the case of coliform and gonococcal infections. Hexyl-resorcinol is best **administered**, dissolved in olive oil, in capsules. It is used in the treatment of pyelitis and cystitis and other infections of the urinary tract. In the pyelitis of infancy and childhood marked improvement in general health and nutrition has frequently been observed following its administration in the form of a 2.5 per cent. solution in olive oil; one fluid-drachm of this contains 0.1 gramme of hexyl-resorcinol and may be given three times a day. Some intestinal irritation may occur in the first few days but soon passes off, and treatment should be persisted in. Hexyl-resorcinol, in doses of 0.5 to 1 gramme, has been used as an anthelmintic

for both round-worms and hook-worms, but its value does not appear to be superior to that of other drugs used for the same purpose.

Hexyl-resorcinol may be used **externally** as a disinfectant of skin and mucous membrane; a solution, 1 in 1000, in a mixture of 3 parts of glycerin and 7 parts of water, by volume, has been found to be the most effective. This solution has the property of reducing surface tension and is said consequently to be more penetrative in action. Some observers state that it is somewhat irritating to the skin and mucous membrane. Hexyl-resorcinol solution may be used for the disinfection of wounds and abrasions and weaker solutions can be applied as a spray or gargle to mucous surfaces.

Dose.—0.12 to 0.6 gramme (2 to 10 grains).

HIRUDO

(Hirudo)

Leeches

Leeches are fresh-water annelids; the speckled or German leech and the green or Hungarian leech are varieties of *Hirudo medicinalis* Linn. (Fam. Hirudinidæ). For medicinal use they are bred in ponds near Hanover, in Germany, and in the South of France; the Australian, or five striped leech, *H. quinquestriata* Schmarda, is found in the Australasian colonies, where it is used instead of the European varieties. Leeches are **stored** in unglazed earthenware pans, half filled with soft water and having pebbles, turf, or moss and charcoal on the bottom; the pans should be covered with muslin. They are kept in a shady place at a temperature between 10° and 20°.

Leeches have soft, smooth bodies marked with from 90 to 100 annulations, about 10 to 12 centimetres long when fully extended, and 3 to 3.5 centimetres when fully contracted, the width in the former condition being from 0.8 to 1 centimetre and in the latter from 1.5 to 1.8 centimetres; they taper towards their extremities, each of which is provided with a disc-shaped sucker. The anterior sucker is the smaller and surrounds the triradiate jaws, by which the leech effects an incision in the skin. The dorsal surface of the speckled leech is olive-green, with six longitudinal stripes, and the ventral surface is greenish-yellow with black spots. The green leech is similar on the dorsal surface, but the ventral surface is olive-green and not spotted. The Australian leech is yellowish-brown on the dorsal surface, which is marked with five longitudinal stripes, and the ventral surface is greenish-yellow and not spotted.

The buccal secretion of leeches **contains** a substance named hirudin, which retards the coagulation of blood. It may be extracted by treating the minced heads with physiological salt solution, at a temperature of 38° to 40°, and can be obtained in brownish lamellæ or light masses. It is readily soluble in water, but insoluble in alcohol and ether.

Action and Uses.—Leeches are applied to a vascular part of the body for the purpose of withdrawing blood from it, thus allaying local inflammation and congestion. The part to be bitten should first be cleansed, moistened with sugar solution and the leech applied by means of a leech glass or perforated pill box. Each leech draws, on an average, about 6 millilitres of blood. The blood drawn does not coagulate, owing to its admixture with the secretion which contains hirudin. If persistent hæmorrhage follows the removal of leeches, it may be arrested by means of a styptic or by the pressure of a pad of cotton fixed with a bandage. Hirudin has been used to prevent the clotting of blood during transfusion and in the treatment of dysmenorrhœas accompanied by clotting.

HOLARRHENA

(*Holarr.*)

Holarrhena

Synonyms—Kurchi; Conessi Bark; Telicherry Bark.

Holarrhena consists of the bark from the stem and root of *Holarrhena antidysenterica* Wall. (Fam. Apocynaceæ), a small tree growing in India.

The bark occurs in curved, channelled or quilled pieces about 1 to 6 centimetres long, 1 to 4 centimetres wide and 1 to 7 millimetres thick. The outer surface is greyish-brown to reddish-brown, frequently covered by grey lichens and showing small black apothecia of lichens, the thicker pieces being rugose and showing numerous yellowish warts. The inner surface is cinnamon-brown, longitudinally striated and frequently has portions of the pale yellow wood attached. The fracture is short and granular; the smoothed, transverse surface is reddish-brown and shows abundant yellowish groups of sclereids with minute, glittering points scattered throughout; only a very few starch grains are present. The drug has no odour and the taste is at first faint and afterwards bitter.

Holarrhena contains the alkaloid conessine, $C_{24}H_{40}N_2$, and also a considerable number of subsidiary alkaloids, as many as ten having been described.

Substitute.—The bark of *Wrightia tinctoria* Br. (Fam. Apocynaceæ) has often been substituted for holarrhena and can be distinguished by the presence of abundant small starch grains filling the cells of the parenchyma. It contains indican.

Action and Uses.—Holarrhena has been used for the treatment of amoebic dysentery in India for many years. It is best administered in the form of a liquid extract in daily doses of 25 to 30 millilitres (6 to 8 fluid drachms). The total alkaloid extracted from the bark, which has been stated to be a more powerful antidyenteric than ametine, is also non-emetic and less toxic; in combination with bismuth iodide

it is known as kurchi-bismuth-iodide and may be administered in doses of 0·6 gramme (10 grains), twice daily, 4 grammes (1 drachm) of sodium bicarbonate and 2·6 grammes (40 grains) of sodium citrate being given thirty minutes previously.

Dose.—0·25 to 0·6 gramme (4 to 10 grains).

HOMATROPINÆ HYDROBROMIDUM

(Homatrop. Hydrobrom.)

Homatropine Hydrobromide

Homatropine hydrobromide is the salt of an alkaloid homatropine which may be obtained by heating tropine and mandelic acid with dilute hydrochloric acid on a water-bath for several days. The alkaloidal base is liberated from the product by means of an alkali, extracted with chloroform and treated with hydrobromic acid, the resulting hydrobromide being purified by recrystallisation. It occurs as a colourless, odourless, crystalline powder which is neutral to litmus. When the alkaloidal base, obtained by the addition of solution of ammonia to an aqueous solution of the hydrobromide, shaking out with chloroform and evaporating the solvent, is warmed with a small quantity of a 1 in 50 solution of mercuric chloride in alcohol (60 per cent.), a yellow precipitate is produced, becoming brick-red. This reaction distinguishes homatropine from most other alkaloids except atropine and hyoscyamine.

Soluble in water (1 in 6), alcohol (90 per cent.) (1 in 18), and dehydrated alcohol (1 in 133); readily soluble in warm alcohol; slightly soluble in chloroform; insoluble in ether.

Standard, B.P.—Homatropine hydrobromide melts at about 214°, with partial decomposition. Ash, not more than 0·1 per cent. It complies also with limit tests for alkaloids precipitated by tannic acid, and for atropine, hyoscyamine and hyoscine.

Action and Uses.—Homatropine is seldom used internally. Its action is similar to that of atropine, but is less powerful. The chief use of homatropine is in ophthalmology to dilate the pupil. Its effect on the eye is similar to that of atropine, but its action is more rapid, persists for a shorter time and passes off in about twenty-four hours. In combination with cocaine its mydriatic action is enhanced. Homatropine has less tendency to increase the intra-ocular tension than atropine, on account of its less prolonged action.

Homatropine hydrobromide is used in aqueous solution, either alone or with cocaine, or as Lamella Homatropinæ, or as a 1 per cent. ointment for the eye, or the alkaloid may be used as a 2 per cent. solution in castor oil. In cases of **poisoning** by homatropine or its salts, emetics should be given or the stomach evacuated and washed out by means of the stomach pump; 10 grains of tannic acid in solution is then given.

In the excitement stage, chloroform or ether may be necessary to control the spasms. In the stage of depression, caffeine, oxygen, or artificial respiration may be employed. Pilocarpine is useless as an antidote to poisoning by homatropine. Solutions of homatropine hydrobromide for **injection** may be sterilised by tyndallisation or by filtration, and the containers should comply with the tests for limit of alkalinity of glass.

Dose.—0.001 to 0.002 gramme ($\frac{1}{84}$ to $\frac{1}{82}$ grain).

Preparation

Lamella Homatropinæ, B.P.—(Larnell. Homatrop.)—Lamella of Homatropine. Each lamella contains 0.00065 gramme ($\frac{1}{160}$ grain) of homatropine hydrobromide.

HYDRARGYRI CYANIDUM

(Hydrarg. Cyanid.)

Mercuric Cyanide

Synonym—Mercury Cyanide.

Mercuric cyanide, $\text{Hg}(\text{CN})_2$, may be prepared by the action of hydrocyanic acid on mercuric oxide, keeping the former in slight excess. It occurs in colourless, transparent or white, prismatic, anhydrous, odourless crystals with a nauseating, metallic taste. It is not decomposed by alkalis; dilute hydrochloric acid, however, decomposes it with evolution of hydrocyanic acid. On heating, it decomposes into mercury and cyanogen.

Soluble in water (1 in 13), boiling water (1 in 3), alcohol (1 in 20) and glycerin (1 in 4); sparingly soluble in ether.

Standard.—Mercuric cyanide contains not less than 99 per cent of $\text{Hg}(\text{CN})_2$. Residue on ignition, not more than 0.1 per cent. A 5 per cent. aqueous solution is neutral to litmus and, on the gradual addition of a few drops of potassium iodide solution, does not yield a red precipitate soluble in excess of the precipitant, or a white precipitate with silver nitrate solution (limit of mercuric chloride). No red colouration is produced on the addition of a few drops of phenolphthalein solution to a solution of mercuric cyanide in sodium chloride solution (limit of mercuric oxycyanide).

Assay.—Dissolve about 0.4 gramme, accurately weighed, in 50 millilitres of water, add 1 gramme of sodium chloride, followed by 2 to 3 grammes of potassium iodide, and titrate with N/10 hydrochloric acid, using methyl orange as indicator; each millilitre of N/10 hydrochloric acid is equivalent to 0.01263 gramme of $\text{Hg}(\text{CN})_2$.

Action and Uses.—Mercuric cyanide is a powerful antiseptic, having the general properties of mercuric salts (see Hydrargyri Perchloridum)

Although quite soluble, it is almost non-ionised and is, therefore, less poisonous than mercuric chloride. It is given internally in syphilis, usually in pill form, the salt being carefully triturated with lactose and massed with a very small quantity of glycerin of tragacanth. A 1 per cent. solution, with or without cocaine, may be injected intravenously, or deeply into muscular tissue, in doses of 1 millilitre daily or on alternate days. **Externally**, mercuric cyanide is used as a paint (1 in 50 to 1 in 100) for syphilitic sores, especially of the tongue and throat, but it must be used with caution. Solutions (1 in 2000 to 1 in 4000) are used as antiseptic eye lotions. A solution (1 in 500) has been employed in ophthalmia neonatorum and (1 in 1000) in ordinary ophthalmia. Solutions for **injection** may be prepared by aseptic methods. In cases of **poisoning** by mercuric cyanide, the antidotes recommended for mercuric chloride may be employed.

Dose.—0.004 to 0.008 gramme ($\frac{1}{18}$ to $\frac{1}{8}$ grain).

HYDRARGYRI ET ZINCI CYANIDUM

(Hydrarg. et Zinc. Cyanid.)

Mercury and Zinc Cyanide

Synonyms—Zinc and Mercury Cyanide; Lister's Salt.

Mercury and zinc cyanide was at one time thought to be a definite compound of the formula $\text{HgZn}(\text{CN})_4$, but later the formula $\text{Zn}_4\text{Hg}(\text{CN})_{10}$ was suggested, and it has also been described as a trizincic monomeric octacyanide of the formula $\text{Zn}_3\text{Hg}(\text{CN})_8$, with a maximum percentage of 38.5 of mercuric cyanide. As it suffers some decomposition during precipitation, owing to the water present, it is usually of varying composition. It is now regarded as merely an intimate mixture of the cyanides, or, at best, a very indefinite molecular combination. It may be prepared by mixing cold solutions of equimolecular quantities of zinc potassium cyanide and mercuric chloride, or of mercuric potassium cyanide and zinc sulphate, washing the precipitate with cold water until the washings are nearly free from mercury, and drying by exposure to the air or, preferably, in a desiccator. By the use of saturated solutions of the reacting salts in equimolecular proportions, a product containing a maximum of about 38 per cent. of mercuric cyanide is obtained; the use of weaker solutions, or of the salts in any proportion other than equimolecular, results in a product weaker in mercuric cyanide. Mercury and zinc cyanide occurs as a white, odourless, amorphous powder.

Very slightly **soluble** in water; soluble in dilute acids.

Action and Uses.—Mercury and zinc cyanide is a powerful germicide and antiseptic, especially suitable for the medication of gauze, wool, lint, etc., since it is not reduced by contact with the organic material of which the dressing is composed. An ointment

(1 per cent. in soft paraffin) is used for syphilitic sores. Mercury and zinc cyanide is frequently coloured with a minute proportion (1 in 50,000) of aniline violet, but, in dispensing, the untinted salt must be used.

Preparation

Carbasus Hydrargyri et Zinci Cyanidi, B.P.C.—(Carbas. Hydrarg. et Zinc. Cyanid.)—Mercury and Zinc Cyanide Gauze. *Syn.*—Double Cyanide Gauze. It contains from 0.5 to 1.5 per cent. of mercury, calculated as $\text{Hg}(\text{CN})_2$, and from 1.5 to 3.0 per cent. of zinc, calculated as $\text{Zn}(\text{CN})_2$.

HYDRARGYRI IODIDUM FLAVUM

(Hydrarg. Iod. Flav.)

Yellow Mercurous Iodide

$\text{HgI} = 327.5$

Yellow mercurous iodide may be prepared by adding to a solution of mercurous nitrate, slowly and with constant stirring, a solution of potassium iodide, collecting the precipitate and washing by decantation until the washings no longer give an acid reaction to litmus. The precipitate is then dried in the dark at a temperature not exceeding 40° . It occurs as a bright yellow, heavy, odourless and tasteless powder. Exposure to light darkens the colour by causing decomposition into metallic mercury and mercuric iodide. Hydrochloric acid and sulphuric acid affect it only slightly. Nitric acid converts it into a white, crystalline, double compound of mercuric oxide and nitrate. When heated to about 70° , it becomes red, and assumes its original yellow colour on cooling. On heating strongly, it volatilises, giving off dark violet vapours. In contact with potassium iodide solution the salt is converted into mercuric iodide, which dissolves, leaving a residue of metallic mercury. It should be **stored** in amber-coloured or black bottles.

Almost **insoluble** in water; insoluble in alcohol and ether.

Standard.—Yellow mercurous iodide, determined by the method of the British Pharmacopœia for Hydrargyri Subchloridum, contains not less than 99 per cent. of HgI , calculated on the substance dried over sulphuric acid; each millilitre of N/10 iodine is equivalent to 0.03275 gramme of HgI . Loss on drying over sulphuric acid, not more than 0.5 per cent. Residue on volatilisation, not more than 0.2 per cent. It complies with the limit tests for soluble mercury salts and chlorides in Hydrargyri Iodidum Rubrum.

Action and Uses.—Yellow mercurous iodide is used for the treatment of syphilis in cases which are unable to tolerate arsphenamine or bismuth. The usual dose for this purpose is $\frac{1}{8}$ grain taken thrice daily in tablet form. An ointment, 1 in 8 (Unguentum Hydrargyri

Iodidi Flavi) is sometimes used for application to enlarged glands and in the treatment of chronic skin diseases. Yellow mercurous iodide is **incompatible** with soluble chlorides or iodides owing to its tendency to form mercuric salts.

Dose.—0·008 to 0·03 gramme ($\frac{1}{8}$ to $\frac{1}{2}$ grain).

HYDRARGYRI IODIDUM RUBRUM

(Hydrarg. Iod. Rub.)

Red Mercuric Iodide

$\text{HgI}_2 = 454\cdot5$

Synonym—Mercuric Iodide.

Red mercuric iodide may be obtained by the interaction of solutions of mercuric chloride and potassium iodide. It occurs as a scarlet-red powder which becomes yellow when heated above 150° and assumes its original colour on cooling. At about 350° it fuses and volatilises, forming a yellow, crystalline sublimate. Red mercuric iodide is readily soluble in an aqueous solution of potassium iodide, forming a solution of double iodide of mercury and potassium, such as the compound of the formula $\text{HgI}_2\cdot 2\text{KI}$; it is also soluble in solutions of mercuric chloride.

Almost **insoluble** in water; soluble in alcohol (90 per cent.) (1 in 300), ether (1 in 150), castor oil (1 in 50) and olive oil (1 in 230).

Standard, B.P.—Red mercuric iodide contains not less than 99 per cent. of HgI_2 . Residue on volatilisation, not more than 0·1 per cent. It complies also with limit tests for soluble mercury compounds and for chloride.

Action and Uses.—Red mercuric iodide is more powerfully antiseptic than mercuric chloride, but is not so irritating, since it combines less readily with albumin. It is administered **internally** for syphilis in solution with potassium iodide, as *Liquor Arseni et Hydrargyri Iodidi*, or in tablets. It may also be given in the form of a solution with potassium iodide (1 per cent. w/v of each), in doses of 0·5 millilitre (8 minims) by intramuscular injection, which, however, cause some pain. A solution of mercuric iodide in olive oil is also used for hypodermic injection. **Externally**, mercuric iodide is a powerful local irritant. Solutions in water or alcohol may be obtained by the addition of four-fifths of its weight of potassium iodide. Solutions so prepared are much used in surgical practice, aqueous solutions (1 in 2000 to 1 in 5000) for application to wounds, and spirituous solutions (1 in 500 to 1 in 2000) for rendering the skin and hands aseptic. Solution-tablets, such as *Solvellæ Hydrargyri Iodidi*, are used for the extemporaneous preparation of mercuric iodide solutions for external use. For use as a vaginal douche, solutions of mercuric iodide (1 in 5000 to 1 in 10,000) are employed. *Unguentum Hydrargyri Iodidi Rubri*

is used for ringworm and lupus and for syphilitic lesions; it is sometimes employed diluted from two to four times. In veterinary practice, a strong ointment (1 to 4) is used to produce vesication. In cases of **poisoning** by mercuric iodide, the antidotes described under Hydrargyri Perchloridum should be employed.

Dose.—0·002 to 0·004 gramme ($\frac{1}{812}$ to $\frac{1}{18}$ grain).

Preparations

Liquor Arseni et Hydrargyri Iodidi, B.P.—(Liq. Arsen. et Hydrarg. Iod.)—

Solution of Arsenous and Mercuric Iodides. *Syn.*—Donovan's Solution. It contains 1 per cent. w/v of red mercuric iodide (limits, 0·95 to 1·05) and total arsenic equivalent to 1 per cent. w/v of arsenic triiodide (limits, 0·95 to 1·05), in distilled water. 1 millilitre contains the equivalent of about 0·01 gramme, and 15 minims about $\frac{1}{8}$ grain, of each salt. The arsenous compound in the solution is rapidly oxidised to the arsenic state in contact with air. The solution should be freshly prepared or, if not used immediately, it should be stored in well-filled containers and protected from light. **Dose.**—0·3 to 1 millilitre (5 to 15 minims).

Sirupus hydrargyri iodidi cum Kalii iodido I.A. contains 0·05 per cent. of mercuric iodide and 2·5 per cent. of potassium iodide.

Liquor Saponis Antisepticus, B.P.C.—(Liq. Sap. Antisept.)—Antiseptic Solution of Soap. *Syn.*—Antiseptic Ethereal Soap; Solutio Saponis Antiseptica. Ethereal solution of soap with 0·05 per cent. w/v of mercuric iodide and of potassium iodide.

Solvellæ Hydrargyri Iodidi, B.P.C.—(Solv. Hydrarg. Iod.)—Mercuric Iodide Solution-Tablets. *Syn.*—Soluble Biniodide Tablets. Each tablet contains $8\frac{1}{2}$ grains of mercuric iodide, with potassium iodide and eosin; one tablet dissolved in 20 fluid ounces of water forms a solution containing 1 in 1000 of mercuric iodide.

Unguentum Hydrargyri Iodidi Rubri, B.P.C.—(Ung. Hydrarg. Iod. Rub.)—Red Mercuric Iodide Ointment. *Syn.*—Ointment of Mercuric Iodide. Red mercuric iodide, 4 per cent., in benzoinated lard.

This ointment was included in the British Pharmacopœia, 1914.

HYDRARGYRI IODIDUM VIRIDE

(Hydrarg. iod. Vir.)

Green Mercurous Iodide

Synonyms—Green Iodide of Mercury; Protoiodide of Mercury.

Green mercurous iodide may be prepared by triturating mercury with a little alcohol and gradually adding iodine in successive small quantities. The trituration should be continued until globules of mercury are no longer visible and the powder is of a uniform greenish-yellow colour. Green mercurous iodide occurs as a greenish-yellow, colourless and tasteless powder. The greenish colour is due to the blue of free mercury blending with the yellow of true mercurous iodide, HgI. On strongly heating, it melts to a brown liquid and then volatilises completely. It is decomposed by exposure to light into mercuric iodide and metallic mercury, by chlorine, into mercuric chloride and

mercuric iodide, by nitric acid into mercuric nitrate and mercuric iodide and by soluble iodides into mercuric iodide and metallic mercury. It contains from about 65 to 75 per cent. of mercury.

Insoluble in water, alcohol and ether.

Action and Uses.—Green mercurous iodide is less potent than the yellow iodide, and is given in syphilis in doses of 0.02 gramme ($\frac{1}{3}$ grain) three times daily, gradually increased. It is **incompatible** with soluble iodides and chlorides.

Dose.—0.01 to 0.06 gramme ($\frac{1}{3}$ to 1 grain).

HYDRARGYRI OXIDUM FLAVUM

(Hydrarg. Oxid. Flav.)

Yellow Mercuric Oxide

HgO = 216.6

Yellow mercuric oxide may be obtained by the interaction of aqueous solutions of mercuric chloride and sodium hydroxide, collecting, washing, and drying the precipitate. It occurs as an orange-yellow, odourless, amorphous powder readily soluble in acids, giving solutions of mercuric salts. When yellow mercuric oxide is heated gently, the colour darkens to red, and when strongly heated, it is decomposed, giving metallic mercury and oxygen. It should be **stored** protected from light.

Insoluble in water and alcohol (90 per cent.).

Standard, B.P.—Yellow mercuric oxide contains not less than 99.3 per cent. of HgO, calculated on the substance dried at 150° for one hour. Loss when heated at 150° for one hour, not more than 1 per cent. Residue on ignition, not more than 0.5 per cent. When shaken with water, the water remains neutral to litmus. It complies also with limit tests for mercurous salts and for chloride.

Action and Uses.—Yellow mercuric oxide is an antiseptic. If taken by the mouth it is converted in the stomach into mercuric chloride and acts as such. Yellow mercuric oxide forms the principal ingredient of Lotio Hydrargyri Flavum, which is used as an application to venereal sores. In the form of an ointment, the oxide is used in the treatment of syphilitic eruptions, chronic eczema, pityriasis and other skin affections. Oculentum Flavum is largely used in ophthalmic practice for application to the eyelids in ophthalmia tarsi and conjunctivitis. When making eye ointments containing the oxide it is usual to incorporate the freshly precipitated oxide, while still moist, with the basis, in order to ensure its reduction to the finest possible state of subdivision and so reduce irritation to a minimum. Pagenstecher's ointment, which is also used for application to the eyes, contains 4 per cent. of the oxide. When Oculentum Hydrargyri Oxidi is prescribed, and the proportion of oxide is not

stated by the prescriber, the ointment containing 1 per cent. of yellow mercuric oxide in *Oculentum Simplex* must be dispensed. Yellow mercuric oxide is **incompatible** with cocaine hydrochloride, mercuric chloride being rapidly formed. The ointment should not be used while iodides are being given internally.

Preparations

Lotio Hydrargyri Flavum, B.P.C.—(Lot. Hydrarg. Flav.)—Yellow Mercurial Lotion. *Syn.*—Yellow Wash. It contains freshly precipitated mercuric oxide, prepared from solution of calcium hydroxide and about 0.5 per cent. w/v of mercuric chloride.

This lotion was included in the British Pharmacopœia, 1914.

Oculentum Atropinæ cum Hydrargyri Oxido, B.P.—(Oculent. Atrop. c. Hydrarg. Oxid.)—Atropine and Yellow Mercuric Oxide Ointment for the Eye. Atropine sulphate, 0.125 per cent., and yellow mercuric oxide, 1 per cent., in simple eye ointment. It should be stored in small, well-closed containers in a cool place and protected from light.

A similar ointment for the eye, prepared with moist yellow mercuric oxide ointment, atropine and yellow soft paraffin, was included in the British Pharmaceutical Codex, 1923.

Oculentum Flavum, B.P.C.—(Oculent. Flav.)—Yellow Eye Ointment. Moist yellow mercuric oxide ointment, 10 per cent., in simple eye ointment; it contains 1 per cent. of yellow mercuric oxide.

Oculentum Hydrargyri Oxidi, B.P.—(Oculent. Hydrarg. Oxid.)—Yellow Mercuric Oxide Ointment for the Eye. Yellow mercuric oxide, 1 per cent., in simple eye ointment. It should be stored in small, well-closed containers in a cool place and protected from light.

An ointment for the eye, prepared with 10 per cent. of moist yellow mercuric oxide ointment and yellow soft paraffin, was included in the British Pharmaceutical Codex, 1923, under the name of Oculentum Flavum.

Unguentum Hydrargyri Flavi, B.P.C.—(Ung. Hydrarg. Oxid. Flav.)—Yellow Mercuric Oxide Ointment. Yellow mercuric oxide, 2 per cent., with liquid paraffin, in yellow soft paraffin.

This ointment, prepared without the liquid paraffin, was included in the British Pharmacopœia, 1914.

Unguentum Hydrargyri Oxidi Flavi Humidi, B.P.C.—(Ung. Hydrarg. Oxid. Flav. Humid.)—Moist Yellow Mercuric Oxide Ointment. It contains approximately 10 per cent. of freshly precipitated yellow mercuric oxide in wool fat, 12.5 per cent., and yellow soft paraffin.

HYDRARGYRI OXIDUM RUBRUM

(Hydrarg. Oxid. Rub.)

Red Mercuric Oxide

HgO = 216.6

Synonyms—Red Precipitate; Red Oxide of Mercury.

Red mercuric oxide may be prepared by heating mercurous nitrate until acid vapours cease to be evolved. It occurs in orange-red crystalline scales or, when levigated, as a red powder. It should be **stored** in well-stoppered bottles and protected from light.

Insoluble in water; soluble in dilute hydrochloric acid and dilute nitric acid.

Standard.—Red mercuric oxide, determined by the method of the British Pharmacopœia for Hydrargyri Oxidum Flavum, contains not less than 99·3 per cent. of HgO , calculated on the substance dried at 150° . Loss on drying at 150° , not more than 1 per cent. Residue on volatilisation, not more than 0·3 per cent. It complies with the test for neutrality and the limit test for chloride in Hydrargyri Oxidum Flavum. When 0·5 gramme is heated on a water-bath with a solution of 1 gramme of oxalic acid in 10 millilitres of water and 1 millilitre of dilute solution of ammonia, no change of colour is produced within two hours (distinction from yellow mercuric oxide). Solutions prepared by dissolving 0·5 gramme in 25 millilitres of dilute hydrochloric acid or dilute nitric acid are not more than slightly turbid (limit of mercurous compounds).

Action and Uses.—Red mercuric oxide is seldom used internally. It is applied in the form of Unguentum Hydrargyri Oxidi Rubri as a parasiticide, for application to syphilitic ulcers, in chronic eczema and in the treatment of seborrhœa and alopecia. Owing to its crystalline character and the difficulty of obtaining it as a minutely subdivided powder, red mercuric oxide is too irritating for ophthalmic use. For the preparation of ointments, the oxide should be in the finest possible powder.

Dose.—0·004 to 0·016 gramme ($\frac{1}{8}$ to $\frac{1}{4}$ grain).

Preparation

Unguentum Hydrargyri Oxidi Rubri, B.P.C.—(Ung. Hydrarg. Oxid. Rub.)—Red Mercuric Oxide Ointment. *Syn.*—Red Precipitate Ointment. Red mercuric oxide, 10 per cent., in yellow paraffin ointment.

This ointment was included in the British Pharmacopœia, 1914.

HYDRARGYRI OXYCYANIDUM

(Hydrarg. Oxycyanid.)

Mercuric Oxycyanide

Mercuric oxycyanide may be prepared by triturating, until finely powdered and intimately mixed, 15 parts of mercuric oxide, 60 parts of mercuric cyanide and 15 parts of water; after a few minutes, 2 parts of 20 per cent. w/v solution of sodium hydroxide are added, and trituration continued until the mixture is white, a further 42·5 parts of water being added gradually to form a cream, which is finally made just acid to phenolphthalein with acetic acid. This cream is added in successive small quantities to a boiling solution of 30 parts of mercuric cyanide in 550 parts of boiling water, complete solution being allowed to take place between each addition. The liquid is filtered at or near

the boiling-point and cooled rapidly to 15° with agitation, when the oxycyanide separates and is collected and dried at a temperature not above 35° . It occurs as a white, crystalline powder with an alkaline reaction. It is free from the liability to explode which is exhibited by other basic cyanides of mercury. The compound having the formula $\text{HgO}, \text{Hg}(\text{CN})_2$ has given rise to fatal accidents during manufacture, since it is liable to explode with some violence when heated to 180° , or during the processes of drying and grinding.

Soluble in water (about 1 in 18).

Standard, B.P.—Mercuric oxycyanide contains not less than 20 per cent. and not more than 22 per cent. of HgO , and not less than 77 per cent. and not more than 79 per cent. of $\text{Hg}(\text{CN})_2$. Loss on drying at 100° , not more than 1 per cent. Residue on ignition, not more than 0.1 per cent. It complies also with a limit test for chloride.

Action and Uses.—Mercuric oxycyanide is a powerful antiseptic which does not precipitate albumin, and in dilute solution does not attack metals. It does not ionise in solution, so that it does not exert either a cyanide or a mercurial action. Solution of mercuric oxycyanide (1 in 500) is used to irrigate the conjunctiva in ophthalmia neonatorum and weaker solutions (1 in 1000 to 1 in 5000) are used in conjunctivitis; dilute solutions (1 in 5000 to 1 in 10,000) are used as injections in gonorrhœa, and a stronger solution (1 in 200) is used for wounds and for sterilising surgical instruments. For internal administration in syphilis it is given in pills containing 0.01 gramme ($\frac{1}{8}$ grain) in each. Intravenous injections are employed in the treatment of syphilis and septicæmia. Mercuric oxycyanide should not be employed while potassium iodide is being given internally. Solutions for **injection** may be prepared by aseptic methods.

Dose.—0.005 to 0.01 gramme ($\frac{1}{40}$ to $\frac{1}{8}$ grain), by intramuscular injection; 0.01 gramme ($\frac{1}{8}$ grain), by intravenous injection.

Preparation

Solvellæ Hydrargyri Oxycyanidi, B.P.C.—(Solv. Hydrarg. Oxycyanid.)—Mercuric Oxycyanide Solution-Tablets. Each tablet contains nearly $4\frac{1}{2}$ grains of mercuric oxycyanide coloured with eosin. One tablet dissolved in 20 fluid ounces of water forms a solution containing 1 in 2000 of mercuric oxycyanide

HYDRARGYRI PERCHLORIDUM

(Hydrarg. Perchlor.)

Mercuric Chloride

Synonyms—Hydrargyri Chloridum Corrosivum; Perchloride of Mercury; Corrosive Sublimate.

Mercuric chloride may be obtained by the direct combination of mercury and chlorine, or by heating a mixture of mercuric sulphate

and sodium chloride with a small amount of manganese dioxide, and collecting the sublimate. It occurs as a heavy, white, crystalline powder, or in colourless or white, rhombic, crystalline masses. When heated, mercuric chloride fuses to a colourless liquid at about 265° ; above 300° it volatilises as a dense, white cloud. The aqueous solution has an acid reaction to litmus, but becomes neutral on the addition of sodium chloride.

Soluble in water (1 in 18), alcohol (90 per cent.) (1 in 4), ether (1 in 4) and glycerin (1 in 2).

Standard, B.P.—Mercuric chloride contains not less than 99.5 per cent. of HgCl_2 . Residue on volatilisation, not more than 0.1 per cent. It complies also with a test for complete solubility in water

Action and Uses.—The action of mercuric chloride may be taken as typical of that of the more soluble salts of mercury. They differ from the salts of other metals, except those of arsenic, in that they are rapidly absorbed. The soluble mercury salts are powerful antiseptics and disinfectants; a 1 in 1000 solution of the perchloride is perhaps the most efficient disinfectant for general use, but even a dilution of 1 in 1,000,000 will inhibit the growth of the anthrax bacillus and most other micro-organisms. Mercury has a specific action against *Treponema pallidum* and is, therefore, largely used in the treatment of primary and secondary syphilis. The development of the disease is aborted if a mercurial ointment, such as a strong calomel ointment, is applied one or two hours after the infection. In tertiary syphilis mercury is less valuable. Syphilis is now, however, rarely treated with mercury alone; it is often used in conjunction with the arsphenamine compounds, bismuth and iodides.

Mercury is also a specific for parasitic skin diseases; for this purpose, one of the oxides or iodides, or the subchloride, is generally employed in the form of an ointment. Mercuric chloride is very easily and rapidly absorbed. This is probably explained by the fact that, although it precipitates protein, the precipitate is readily soluble in an excess of protein, and since the protein is almost always in excess owing to the small amount of mercury likely to be used in practice, solutions of mercuric chloride are almost non-astringent. Owing to its rapid absorption and the rapidity with which it produces specific effects, it is not so suitable for disinfecting the lower alimentary canal as some of the less soluble salts of mercury, such as calomel.

As an antiseptic and disinfectant, a 1 in 1000 solution in water forms a suitable solution for general purposes, but a 1 in 1000 solution in 70 per cent. alcohol is greatly superior. For general surgical purposes, such as irrigation, cleansing of wounds, etc., solutions from 1 in 10,000 to 1 in 100,000 are employed. The latter strength (i.e. 1 in 100,000) is suitable for vaginal injection. It should be noted that a solution of mercuric chloride should not be used as a sterilising fluid for steel instruments since a deposit of mercury is formed on them. A

dilute solution of mercury oxycyanide may, however, be used for this purpose. In the preparation of solutions for surgical purposes, 5 parts of tartaric acid are sometimes added to each part of mercuric chloride used. This addition is said to render the antiseptic action more effective, probably by lessening, still further, the formation of any insoluble albuminate. Alcoholic solutions of mercuric chloride are sometimes used for sterilising the skin prior to operation; they are said to be less irritant than solutions of iodine. Harrington's solution contains 0.08 part of mercuric chloride, 64 parts of alcohol (90 per cent.), 6 parts of hydrochloric acid and 30 parts of water. The addition of sodium chloride or ammonium chloride to solutions of mercuric chloride is said to increase its antiseptic power. For convenience, solution-tablets (*Solvellæ*) are prepared. For disinfecting clothes and utensils a 1 in 2000 solution of mercuric chloride is sufficiently strong. As a disinfectant for excreta, a solution of 1 part of mercuric chloride and 25 parts of hydrochloric acid diluted to 500 parts with water is used, especially in cases of typhoid.

For eye lotions, mouth-washes and urethral injections, 1 in 10,000 to 1 in 4500 solutions of mercuric chloride are used. As a parasiticide to destroy pediculi, a solution of 1 in 2000 is of use. Ointments of mercuric chloride (0.5 to 1.5 per cent.) are also employed in parasitic skin diseases. In the preparation of such ointments, the salts must be added in aqueous or glycerin solution. Gauze, wool and lint, medicated with mercuric chloride, are liable to lose their antiseptic properties owing to reduction of the salt by the organic material of the dressing.

Mercuric chloride is **administered** by the mouth as *Liquor Hydrargyri Perchloridi*, or by intravenous injection of a solution containing 0.002 to 0.004 gramme ($\frac{1}{32}$ to $\frac{1}{16}$ grain) in 5 millilitres (75 minims). Solutions for **injection** may be prepared by aseptic methods.

Liquor Hydrargyri Perchloridi is often dispensed with potassium iodide, in which case red mercuric iodide is formed but passes into solution in the presence of an excess of the potassium salt. Pills may be prepared by carefully triturating the salt with lactose so as to obtain thorough admixture, and massing as desired. When dispensing mercuric chloride, steel implements, such as spatulas, must not be used. Solutions of mercuric chloride for external use should be coloured with methylene blue. Mercuric chloride is **incompatible** with alkalis, lead acetate, silver nitrate, alkaloids (especially when iodides are present) and with vegetable astringents. Solutions made with tap water will yield a slight deposit on standing. In acute mercurial **poisoning**, there is violent gastro-enteritis and diarrhœa, which generally yields to treatment; this is followed in a day or two by stomatitis and all the signs of acute nephritis. If the nephritis is not immediately fatal, symptoms resembling those of phosphorus poisoning may supervene, and death may not occur for several weeks. Chronic mercurial poisoning (mercurialism) is characterised by salivation,

foetid breath, loosening of the teeth, swollen and ulcerated gums, muscular tremors and paralysis. It is well to remember that albuminuria is common after the therapeutic use of mercurials, and that slightly larger doses may cause nephritis. In cases of acute poisoning, fresh white of egg should be administered as soon as possible, and emetics should be given. Heat should be applied to the body, and stimulants given.

Dose.—0.002 to 0.004 gramme ($\frac{1}{8}$ to $\frac{1}{8}$ grain).

SAL ALEMBROTH.—Alembroth salt, $(\text{NH}_4)_2\text{HgCl}_4 \cdot \text{H}_2\text{O}$, may be prepared by mixing hot, strong solutions of mercuric chloride and ammonium chloride, and evaporating the solution. It occurs as a granular powder or in the form of colourless crystals. Sal alembroth is a powerful antiseptic and was used formerly in the preparation of gauze, wool and lint, which were said to retain their strength for a longer period than dressings made with mercuric chloride.

Preparations

Carbasus Hydrargyri Perchloridi, B.P.C.—(Carbas. Hydrarg. Perchlor.)—Mercuric Chloride Gauze. *Syn.*—Sublimate Gauze. It contains about 0.1 per cent of mercuric chloride, but is liable to considerable variation in strength.

Liquor Hydrargyri Perchloridi, B.P.—(Liq. Hydrarg. Perchlor.)—Solution of Mercuric Chloride. An aqueous solution containing 0.1 per cent. w/v of mercuric chloride (limits, 0.095 to 0.105). 4 millilitres contains 0.004 gramme, and 1 fluid drachm contains about $\frac{1}{8}$ grain, of mercuric chloride. It should be stored protected from light. *Dose.*—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Solvellæ Hydrargyri Perchloridi, B.P.C.—(Solv. Hydrarg. Perchlor.)—Mercuric Chloride Solution-Tablets. *Syn.*—Antiseptic Perchloride Tablets; Antiseptic Corrosive Sublimate Tablets. Each tablet contains $8\frac{1}{2}$ grains of mercuric chloride with sodium chloride and methylene blue. One tablet dissolved in 20 fluid ounces of water forms a solution containing 1 in 1000 of mercuric chloride.

HYDRARGYRI SALICYLAS

(Hydrarg. Salicyl.)

Mercury Salicylate

Mercury salicylate may be prepared by boiling an aqueous solution of salicylic acid with yellow mercuric oxide. The product is an organo-metallic compound, in which the functions of the mercury are modified so that it is not precipitated by the usual reagents. It occurs as a white or faintly pink, amorphous, tasteless, odourless powder, neutral to litmus. The compound is not affected by weak acids, but is decomposed by strong mineral acids.

Almost **insoluble** in water and organic solvents; soluble in solutions of alkali hydroxides and carbonates and in warm solutions of alkali halides, the cooled solution depositing double salts.

Standard.—Mercury salicylate contains not less than 54 per cent. and not more than 59.6 per cent. of Hg. Residue on gentle ignition

at about 300° , not more than 0.2 per cent. 0.2 gramme dissolves completely in 4 millilitres of N/1 sodium hydroxide. 0.1 gramme shaken with 5 millilitres of hydrogen sulphide solution produces no immediate darkening. 1 gramme, shaken with 30 millilitres of chloroform and filtered, leaves, on evaporation of the filtrate, not more than 0.001 gramme of residue (limit of free salicylic acid).

Assay.—Dissolve about 0.5 gramme, accurately weighed, in 20 millilitres of N/1 sodium hydroxide; acidify with 20 millilitres of acetic acid and add 50 millilitres of N/10 iodine; allow to stand for three hours, and titrate with N/10 sodium thiosulphate; each millilitre of N/10 iodine is equivalent to 0.01003 gramme of Hg.

Action and Uses.—Mercury salicylate is used as an antiseptic and antisiphilitic, in the form of dusting powder and ointment (1 in 100), or is given in pills. For intramuscular injection, a suspension in liquid paraffin (1 in 10) is employed; the dose given hypodermically is sometimes gradually increased to 0.09 gramme ($1\frac{1}{2}$ grains). Preparations for **injection** should be made by suspending the mercury salicylate in an oily medium which has been heated at 150° for one hour, and the final containers should be sterilised by tyndallisation. Mercury salicylate is **incompatible** with potassium iodide.

Dose.—0.003 to 0.02 gramme ($\frac{1}{30}$ to $\frac{1}{5}$ grain).

HYDRARGYRI BENZOAS.—Mercuric benzoate, $(C_6H_5COO)_2Hg, H_2O$, is a white, crystalline salt given in doses of 0.0025 to 0.006 gramme ($\frac{1}{80}$ to $\frac{1}{16}$ grain) by intramuscular injection, or by the mouth, in the treatment of syphilis.

HYDRARGYRI SUCCINIMIDUM.—Mercury succinimide has been given by hypodermic injection in doses of 0.016 gramme ($\frac{1}{4}$ grain) in the treatment of syphilis. The injections are painful and solutions may, therefore, contain a small quantity of a cocaine salt. Solutions of mercury succinimide for injection may be sterilised by heating at 100° for thirty minutes or by tyndallisation.

HYDRARGYRI SUBCHLORIDUM

(Hydrarg. Subchlor.)

Mercurous Chloride

Synonyms—Calomel; Subchloride of Mercury.

Mercurous chloride may be prepared by heating a mixture of mercurous sulphate and sodium chloride, collecting the sublimate, washing it with water until free from mercuric chloride which is always formed during sublimation, and drying. It occurs as a dull, white, heavy powder, becoming yellow when triturated or compressed. When heated, it volatilises at about 383° without previous fusion. Heated with anhydrous sodium carbonate, it is decomposed, giving a sublimate of metallic mercury. It is blackened by contact with alkalis,

owing to the formation of mercurous oxide. Mercurous chloride in a finely divided condition may be prepared by sifting the sublimed variety through a silk sieve, containing not less than 120 meshes per inch, or by precipitation.

Insoluble in water, alcohol (90 per cent.), ether and cold dilute acids

Standard, B.P.—Mercurous chloride contains not less than 99.6 per cent. of HgCl . Residue on volatilisation, not more than 0.1 per cent. It complies also with a limit test for mercuric chloride, and with a test for absence of ammoniated mercury.

Action and Uses.—Mercurous chloride is practically non-corrosive to the alimentary canal. It is excreted partly unchanged and partly as sulphide in the fæces. In small, repeated doses, it is useful for disinfecting the bowel in the treatment of common bilious attack, especially as its mildly irritant properties produce a slight purgative effect. As a purgative in large doses, when constipation is due to obstruction, mercurous chloride should be used with care, since, if its elimination is delayed, absorption may take place causing toxic symptoms. When given as a purgative, it is advisable to administer mercurous chloride at night, and to give a saline purgative before breakfast the following morning to minimise the possibility of the absorption of the mercurial. Repeated doses of 0.01 gramme ($\frac{1}{8}$ grain) of mercurous chloride are useful in follicular tonsillitis. It has also been used in acute dysentery, often with ipecacuanha, and in cholera and enteric fever. It exerts a marked diuretic action in some cases of cardiac dropsy. As a purgative, mercurous chloride is often combined with colocynth, as in *Pilulæ Hydrargyri Subchloridi, Colocynthidis et Hyoscyami* and *Pilulæ Hydrargyri Subchloridi et Colocynthidis*. In the form of ointment, it is used as an anti-pruritic in the treatment of eczema, psoriasis and pruritus ani.

Mercurous chloride is **administered** in the form of powders, tablets and pills. It is said to cause less irritation to the bowel if the dose is combined with 10 grains of sodium bicarbonate.

Like all mercurials, mercurous chloride has an antisyphilitic action. Ointments containing 30 to 50 per cent. of mercurous chloride are used as prophylactics against syphilis, and are said to be effective when applied within four hours of contact. In the form of *Injectio Hydrargyri Subchloridi* it is used intramuscularly for syphilis; it is very slowly absorbed, and may give rise to pain. Preparations for **injection** should be made by suspending the mercurous chloride in an oily medium which has been heated at 150° for one hour, and the final containers should be sterilised by tyndallisation. Mercurous chloride is **incompatible** with alkali chlorides, bromides and iodides, hydroxides and soaps. Mucilage of acacia or tragacanth must not be used with it, since a cement-like substance is produced.

Dose.—0.03 to 0.2 gramme ($\frac{1}{2}$ to 3 grains), 0.03 to 0.06 gramme ($\frac{1}{2}$ to 1 grain), by intramuscular injection.

Preparations

Injectio Hydrargyri Subchloridi, B.P.—(Inj. Hydrarg. Subchlor.)—Injection of Mercurous Chloride. *Syn.*—Calomel Injection. A sterile preparation containing mercurous chloride, about 5 per cent. w/v, with sterilised wool fat, camphor, creosote and sterilised olive oil. 1·2 millilitres contains about 0·06 gramme, and 20 minims contains about 1 grain, of mercurous chloride. Dose.—0·6 to 1·2 millilitres (10 to 20 minims), by intramuscular injection

An injection prepared with japan wax and almond oil, in place of wool fat and olive oil, was included in the British Pharmaceutical Codex, 1923.

Lotio Hydrargyri Nigra, B.P.—(Lot. Hydrarg. Nig.)—Black Mercurial Lotion. *Syn.*—Black Wash. It contains mercurous oxide equivalent to 0·7 per cent. w/v of mercurous chloride, with glycerin and solution of calcium hydroxide.

Pilulæ Hydrargyri Subchloridi, Colocynthis et Hyoscyami, B.P.C.—(Pil. Hydrarg. Subchlor. Colocynth. et Hyoscy.)—Mercurous Chloride, Colocynthis and Hyoscyamus Pills. *Syn.*—Calomel, Colocynthis and Hyoscyamus Pills; Zittmann's Pills. Each pill contains 1 grain of mercurous chloride, 2½ grains of compound extract of colocynthis and 1 grain of dry extract of hyoscyamus. Dose.—1 or 2 pills.

Pilulæ Hydrargyri Subchloridi Compositæ, B.P.C.—(Pil. Hydrarg. Subchlor. Co.)—Compound Mercurous Chloride Pills. *Syn.*—Compound Calomel Pills; Plummer's Pill. Each pill contains 1 grain of mercurous chloride, 1 grain of sulphurated antimony and 2 grains of guaiacum resin. Dose.—1 or 2 pills.

The mass with which these pills are made was included in the British Pharmacopæia, 1914, under the name of Pilula Hydrargyri Subchloridi Composita.

Pilulæ Hydrargyri Subchloridi et Colocynthis, B.P.C.—(Pil. Hydrarg. Subchlor. et Colocynth.)—Mercurous Chloride and Colocynthis Pills. *Syn.*—Calomel and Colocynthis Pills. Each pill contains 1 grain of mercurous chloride and 4 grains of compound extract of colocynthis. Dose.—1 pill.

Pilulæ Podophyllini Compositæ, B.P.C.—(Pil. Podoph. Co.)—Compound Podophyllin Pills. Each pill contains ¼ grain of resin of podophyllum, 1 grain of mercurous chloride and ½ grain of dry extract of belladonna. Dose.—1 pill

Unguentum Hydrargyri Subchloridi Compositum, B.P.C.—(Ung. Hydrarg. Subchlor. Co.)—Compound Mercurous Chloride Ointment. *Syn.*—Calomel Cream; Prophylactic Ointment. Mercurous chloride, 25 per cent., and mercuric oxycyanide, 0·075 per cent., in wool fat, yellow soft paraffin and liquid paraffin.

Unguentum Hydrargyri Subchloridi, B.P.—(Ung. Hydrarg. Subchlor.)—Ointment of Mercurous Chloride. *Syn.*—Mercurous Chloride Ointment; Calomel Ointment. Mercurous chloride, 20 per cent., in simple ointment.

HYDRARGYRI SULPHIDUM RUBRUM

(Hydrarg. Sulphid. Rub.)

Red Mercuric Sulphide

HgS = 232·7

Synonyms—Cinnabar; Vermilion; Chinese Red

Red mercuric sulphide is found naturally in large quantities. Commercially, however, it is usually prepared either by subliming a mixture of mercury and sulphur, powdering the sublimate and elutriating, or by the wet process, that is, by triturating mercury and

sulphur until black, adding solution of potassium hydroxide, and heating the mixture. The former method is more commonly used. Red mercuric sulphide occurs as a brilliant, scarlet-red, heavy powder, very soft to the touch, and without taste or odour. Exposure to light gradually destroys the bright colour. Heated in a test-tube, it becomes nearly black, yielding metallic mercury and sulphur dioxide and, if pure, volatilising without residue. The finer qualities of vermilion are said to owe their superiority of shade to the care used in subliming. It is unaffected by the dilute mineral acids and acetic acid, but is appreciably soluble in hot concentrated hydrochloric acid. Hot nitric acid decomposes it, precipitating a portion of the sulphur; nitro-hydrochloric acid dissolves it, with decomposition; alkaline liquids have no effect.

Insoluble in water and alcohol.

Action and Uses.—Red mercuric sulphide is occasionally used in the form of ointment (1 or 2 per cent.) as an antiseptic in chronic skin diseases.

HYDRARGYRI PERSULPHAS.—Hydrargyri Sulphas Albus, or mercuric sulphate, HgSO_4 , may be obtained by boiling mercury in excess of strong sulphuric acid, with or without the addition of nitric acid, and, carefully, with constant stirring, continuing the heating until the crystalline powder becomes perfectly dry and white. It occurs as a heavy, white, crystalline powder.

HYDRARGYRI SUBSULPHAS FLAVUS.—Turpeth mineral, or mercury oxy-sulphate, $\text{HgSO}_4 \cdot 2\text{HgO}$, is obtained from mercuric sulphate by trituration with water. It occurs as a heavy, yellow powder. It was formerly used as an ointment for ringworm and seborrhœa capitis.

HYDRARGYRI SUBSULPHIDUM NIGRUM.—Ethiop's mineral, Hydrargyri Sulphuretum Nigrum, Hydrargyrum cum Sulphure, Hydrargyri Sulphuretum cum Sulphure, or black mercuric sulphide, occurs as a heavy, black or greyish-black, amorphous powder. It possesses little or no medicinal activity.

HYDRARGYRI TANNAS

(Hydrarg. Tann.)

Mercurous Tannate

Synonym—Mercury Tannate.

Mercurous tannate may be prepared by triturating 50 parts of freshly prepared and oxide-free mercurous nitrate with 30 parts of tannic acid and 50 parts of distilled water until a perfectly uniform paste is obtained; a large volume of water is then added, decanted, and the greenish precipitate repeatedly washed with cold water until free from nitric acid, collected, pressed, and dried between 36° and 40° . Mercurous tannate occurs as a dull brownish-green powder, or in scales, without taste or odour, containing usually from 40 to 50 per cent. of mercury. Very dilute hydrochloric acid does not alter it perceptibly, but concentrated hydrochloric acid, especially in the presence

of alcohol, converts it into mercuric chloride, tannic acid remaining in solution. Caustic alkalis and alkali carbonates produce a separation of metallic mercury in a very fine granular state, while the alkaline tannic acid solution, owing to oxidation, assumes a brown colour. It should be **stored** in well-closed, amber-coloured bottles

Insoluble in water.

Action and Uses.—Mercurous tannate has been used in syphilis, and produces a mild mercurial action without derangement of digestion or unpleasant after-effects. It may be **administered** in pills or tablets. A small dose of powdered opium is added, if necessary, to prevent diarrhœa.

Dose.—0·06 to 0·12 gramme (1 to 2 grains).

HYDRARGYRUM

(Hydrarg.)

Mercury

Hg = 200·6

Synonym—Quicksilver.

Mercury is obtained chiefly from cinnabar, an impure sulphide found in China, Spain, Austria and California. The mercury is extracted by roasting, when the sulphur is converted into sulphur dioxide and the mercury volatilises and is condensed in suitable receivers; it is also obtained by distillation with lime. It occurs as a heavy, shining, silvery-white, very mobile liquid, easily divisible into globules. The specific gravity is about 13·5. When heated, it readily volatilises and boils at about 358°. It solidifies on cooling to about -39·5°, forming a ductile malleable mass. Impure mercury leaves a track when poured over a clean glass plate; mechanical impurities may be removed by squeezing it through chamois leather. Mercury is insoluble in hydrochloric acid, but dissolves in nitric acid and in hot sulphuric acid, forming solutions of mercuric and mercurous salts. It may be reduced to a very fine state of division by trituration with various substances such as chalk or grease. It unites with many other metals to form amalgams.

Insoluble in water and alcohol.

Standard, B.P.—Mercury contains not less than 99·5 per cent. of Hg. Residue on volatilisation at about 300°, not more than 0·02 per cent.

Action and Uses.—Mercury, in a finely divided state, is absorbed either through the skin or from the alimentary tract, producing the effects described under Hydrargyri Perchloridum. As a purgative, mercury is **administered** by the mouth in the form of Pilula Hydrargyri or

Pilulæ Hydrargyri cum Rheo. Hydrargyrum cum Creta is also used as a mild purgative, especially for children, and as an antiseptic in the alimentary canal; it is administered in powders or cachets, usually mixed with an equal weight of lactose, or with rhubarb and sodium bicarbonate, and in pills or tablets. Pills are prepared by massing gently with syrup of liquid glucose, adding powdered liquorice to increase their size if necessary. It should be rubbed lightly in mixing with other powders, or the mercury may separate. Mercury and chalk powders should not be kept too long in wrapped form on account of oxidation and loss of mercury.

In the treatment of syphilis, mercury may be administered orally as **Pilulæ Hydrargyri cum Creta et Opii**, and may be injected intramuscularly in the form of **Injectio Hydrargyri** or **Injectio Hydrargyri Fortis**. Preparations for **injection** should be made by suspending the mercury in an oily medium which has been heated at 150° for one hour, an antiseptic such as phenol being added. **Externally**, **Unguentum Hydrargyri** (30 to 60 grains daily) may be administered by inunction for syphilis. In the treatment of chronic synovitis and enlarged joints, **Unguentum Hydrargyri Compositum** is employed. **Unguentum Hydrargyri Nitratis Forte** is applied as an antiseptic in chronic skin diseases, such as eczema and psoriasis. It is, however, usually found to be too irritating for general use, and the weaker **Unguentum Hydrargyri Nitratis Dilutum** is preferred. **Liquor Hydrargyri Nitratis Acidus** is a strongly corrosive liquid, and is used as a caustic for syphilitic warts, ulcers, lupus patches, etc. It should be carefully applied by means of a glass rod.

Doses.—0.03 to 0.2 gramme ($\frac{1}{2}$ to 3 grains), by the mouth; 0.03 to 0.06 gramme ($\frac{1}{2}$ to 1 grain), by intramuscular injection.

Preparations

Emplastrum Hydrargyri, B.P.C.—(Emp. Hydrarg.)—Mercurial Plaster. Mercury, about 1 in 3, with olive oil, sublimed sulphur and plaster of lead.

This plaster was included in the British Pharmacopæia, 1914.

Hydrargyrum cum Creta, B.P.—(Hydrarg. c. Cret.)—Mercury with Chalk. **Syn.**—Grey Powder. Mercury, 33 per cent. (limits, 31 to 35), with chalk. It should be stored in well-closed bottles in a cool place. **Dose.**—0.06 to 0.3 gramme (1 to 5 grains).

Injectio Hydrargyri, B.P.—(Inj. Hydrarg.)—Injection of Mercury. **Syn.**—Mercurial Cream. A sterile preparation containing mercury, about 10 per cent. w/v, wool fat, camphor, creosote and sterilised olive oil. 0.6 millilitre contains about 0.06 gramme, and 10 minims contains about 1 grain, of mercury. **Dose.**—0.3 to 0.6 millilitre (5 to 10 minims), by intramuscular injection.

An injection, prepared with japan wax and almond oil in place of wool fat and olive oil, and containing slightly larger proportions of camphor and creosote, was included in the British Pharmaceutical Codex, 1923, under the name of Injectio Mercurialis.

Injectio Hydrargyri Fortis, B.P.C.—(Inj. Hydrarg. Fort.)—Strong Injection of Mercury. **Syn.**—Oleum Cinereum; Grey Oil. It contains 40 per cent. w/v of mercury. **Dose.**—0.06 to 0.12 millilitre (1 to 2 minims), by intramuscular injection.

Linimentum Hydrargyri, B.P.C.—(Lin. Hydrarg.)—Liniment of Mercury. Ointment of mercury, about 30 per cent. w/v, equivalent to about 9 per cent. w/v of metallic mercury, with dilute solution of ammonia and liniment of camphor.

This liniment was included in the British Pharmacopœia, 1914.

Liquor Hydrargyri Nitratis Acidus, B.P.C.—(Liq. Hydrarg. Nit. Acid.)—Acid Solution of Mercuric Nitrate. A solution of mercury in nitric acid, containing the equivalent of 1 in 3 by weight of mercury.

This solution was included in the British Pharmacopœia, 1914.

Pigmentum Hydrargyri Nitratis, B.P.C.—(Pig. Hydrarg. Nit.) Mercuric Nitrate Paint. *Syn.*—Guttæ Hydrargyri Nitratis; Mercuric Nitrate Drops. Dilute ointment of mercuric nitrate, 1 in 16, in arachis oil.

Pigmentum Hydrargyri Nitratis cum Menthole, B.P.C.—(Pig. Hydrarg. Nit. c. Menthol.)—Mercuric Nitrate Paint with Menthol. Dilute ointment of mercuric nitrate, 1 in 16, and menthol, 1 in 100, in arachis oil.

Pilula Hydrargyri, B.P.—(Pil. Hydrarg.)—Pill of Mercury. *Syn.*—Mercury Pill; Blue Pill. Mercury, 33 per cent. (limits, 32 to 34), with syrup, liquid glucose, glycerin and liquorice. Dose.—0.25 to 0.5 gramme (4 to 8 grains).

Pilulæ Colchici et Hydrargyri, B.P.C.—(Pil. Colch. et Hydrarg.)—Colchicum and Mercury Pills. Each pill contains $\frac{1}{2}$ grain of dry extract of colchicum, $\frac{1}{2}$ grain of pill of mercury and $\frac{1}{2}$ grain of compound extract of colocynth. Dose.—1 to 3 pills.

Pilulæ Colchici et Hydrargyri Compositæ, B.P.C.—(Pil. Colch. et Hydrarg. Co.)—Compound Colchicum and Mercury Pills. *Syn.*—Brodie's Gout Pills. Each pill contains $\frac{1}{2}$ grain of dry extract of colchicum and $1\frac{1}{2}$ grains each of pill of mercury, compound extract of colocynth and extract of rhubarb. Dose.—1 or 2 pills.

Pilulæ Colocynthis et Hydrargyri, B.P.C.—(Pil. Colocynth. et Hydrarg.)—Colocynth and Mercury Pills. Each pill contains 2 grains of compound extract of colocynth and 3 grains of pill of mercury. Dose.—1 or 2 pills.

Pilulæ Colocynthis et Hydrargyri Compositæ, B.P.C.—(Pil. Colocynth. et Hydrarg. Co.)—Compound Colocynth and Mercury Pills. Each pill contains $\frac{1}{2}$ grain of pill of colocynth and hyoscyamus and $\frac{1}{2}$ grain of pill of mercury. Dose.—1 to 4 pills.

Pilulæ Digitalis Compositæ, B.P.C.—(Pil. Digit. Co.)—Compound Digitalis Pills. *Syn.*—Pilulæ Digitalis cum Scilla; Guy's Pills; Niemeyer's Pills. Each pill contains 1 grain each of powdered digitalis, squill, and pill of mercury. Dose.—1 or 2 pills.

Pilulæ Hydrargyri cum Creta et Opii, B.P.C.—(Pil. Hydrarg. c. Cret. et Opii)—Mercury with Chalk and Opium Pills. *Syn.*—Hutchinson's Pills. Each pill contains 1 grain of mercury with chalk and 1 grain of powder of ipecacuanha and opium. Dose.—1 pill.

Pilulæ Hydrargyri cum Rheo, B.P.C.—(Pil. Hydrarg. c. Rheo)—Mercury Pills with Rhubarb. Each pill contains $2\frac{1}{2}$ grains of pill of mercury and $2\frac{1}{2}$ grains of compound pill of rhubarb. Dose.—1 pill.

Unguentum Hydrargyri, B.P.—(Ung. Hydrarg.)—Ointment of Mercury. *Syn.*—Mercury Ointment; Unguentum hydrargyri I.A. Mercury, 30 per cent. (limits, 29 to 31), in suet and benzoined lard.

Unguentum Hydrargyri Compositum, B.P.—(Ung. Hydrarg. Co.)—Compound Ointment of Mercury. *Syn.*—Compound Mercury Ointment; Scott's Dressing. Mercury ointment, 40 per cent., with yellow beeswax, olive oil and camphor. It contains 12 per cent. of mercury (limits, 11.5 to 12.5).

Unguentum Hydrargyri, Plumbi et Zinci, B.P.C.—(Ung. Hydrarg. Plumb. et Zinc.)—Mercury, Lead and Zinc Ointment. *Syn.*—Unguentum Metallorum. Ointment of mercuric nitrate, ointment of lead subacetate and ointment of zinc oxide, equal parts.

Unguentum Hydrargyri Nitratis Dilutum, B.P.—(Ung. Hydrarg. Nit. Dil.)—Dilute Ointment of Mercuric Nitrate. *Syn.*—Diluted Mercuric Nitrate Ointment. Strong ointment of mercuric nitrate, 20 per cent., in yellow soft paraffin.

Unguentum Hydrargyri Nitratis Forte, B.P.—(Ung. Hydrarg. Nit. Fort.)—Strong Ointment of Mercuric Nitrate. *Syn.*—Unguentum Hydrargyri Nitratis; Mercuric Nitrate Ointment. A solution of mercury in nitric acid added to a mixture of olive oil and lard heated at 150°. It contains not less than the equivalent of 6·7 per cent. of Hg.

Unguentum Mercuriale, B.P.C.—(Ung. Mercur.)—Mercurial Ointment. *Syn.*—Unguentum Hydrargyri Mite; Blue Ointment; Trooper's Ointment. Ointment of mercury, 33·3 per cent., with lard.

HYDRARGYRUM AMMONIATUM

(Hydrarg. Ammon.)

Ammoniated Mercury

Synonyms—White Precipitate; Mercuric-Ammonium Chloride

Ammoniated mercury may be prepared by dissolving 60 parts of mercuric chloride in 1200 parts of distilled water and pouring the solution, with constant stirring, into 80 parts of dilute solution of ammonia diluted with 400 parts of distilled water; the resulting precipitate is washed with cold water until the washings are nearly free from chloride, and dried at a low temperature. It occurs as a white, odourless powder with an earthy, somewhat metallic taste, and is stable in air. It is slowly decomposed by cold water, rapidly by boiling water, a yellow basic salt of the composition, $\text{NH}_2\text{HgCl}\cdot\text{HgO}$, being formed. Warmed with sodium hydroxide solution, ammonia is evolved and yellow mercuric oxide produced. When strongly heated, it is decomposed and volatilised without previous fusion. It dissolves in hot solutions of ammonium salts, and in a cold concentrated solution of sodium thiosulphate with evolution of ammonia. Ammoniated mercury should be **stored** protected from light.

Insoluble in water, alcohol and ether; soluble in warm hydrochloric, nitric and acetic acids.

Standard, B.P.—Ammoniated mercury contains not less than 97 per cent. and not more than the equivalent of 100·5 per cent. of NH_2HgCl . Residue on ignition at a low red heat, not more than 0·2 per cent. It complies also with a limit test for mercurous chloride and for carbonate.

Action and Uses.—Ammoniated mercury is more irritating than the oxides of mercury, and is not given internally. It is used, principally in the form of Unguentum Hydrargyri Ammoniatum and of Unguentum Hydrargyri Ammoniatum Dilutum, to destroy pediculi and as an application to the skin in eczema, impetigo, herpes, scabies and other parasitic skin diseases.

Preparations

Unguentum Hydrargyri Ammoniati, B.P.—(Ung. Hydrarg. Ammon.)—Ointment of Ammoniated Mercury. *Syn.*—Ammoniated Mercury Ointment; White Precipitate Ointment. Ammoniated mercury, 5 per cent., in simple ointment.

Unguentum Hydrargyri Ammoniati Dilutum, B.P.C.—(Ung. Hydrarg. Ammon. Dil.)—Dilute Ammoniated Mercury Ointment. Ointment of ammoniated mercury and simple ointment, equal parts.

Unguentum Hydrargyri Ammoniati et Zinci Oxidi, B.P.C.—(Ung. Hydrarg. Ammon. et Zinc. Oxid.)—Ammoniated Mercury and Zinc Oxide Ointment. Ointment of ammoniated mercury and ointment of zinc oxide, equal parts.

HYDRARGYRUM OLEATUM

(Hydrarg. Oleat.)

Oleated Mercury

Oleated mercury is prepared, as described in the British Pharmacopœia, by triturating yellow mercuric oxide with liquid paraffin, and heating the mixture at 50° with oleic acid until combination is effected. It occurs as a greyish mass of ointment-like consistence.

Standard, B.P.—Oleated mercury contains the equivalent of not less than 19 per cent. and not more than 21 per cent. of yellow mercuric oxide.

Action and Uses.—Oleated mercury is used almost entirely in the form of Unguentum Hydrargyri Oleati for application to syphilitic lesions, ringworm, enlarged glands and inflamed joints, for the destruction of pediculi, and as a stimulating antiseptic in eczema and other chronic skin diseases. The ointment is sometimes used in the treatment of syphilis by inunction, but is more irritating than Unguentum Hydrargyri, over which it possesses no advantages.

Preparation

Unguentum Hydrargyri Oleati, B.P.—(Ung. Hydrarg. Oleat.)—Ointment of Oleated Mercury. *Syn.*—Mercuric Oleate Ointment. Oleated mercury, 25 per cent., in simple ointment.

HYDRASTINÆ HYDROCHLORIDUM

(Hydrastin. Hydrochlor.)

Hydrastine Hydrochloride

Hydrastine hydrochloride is the hydrochloride of the alkaloid hydrastine obtained from the rhizome and roots of *Hydrastis canadensis*

Linn. It occurs as a white or creamy white, odourless and hygroscopic powder, having a very bitter, pungent taste. With sulphuric acid, a yellow colour is produced which becomes purple on heating. Sulphuric acid with a trace of molybdic acid gives a green colour, changing to olive-green and then brown. Nitric acid produces a reddish-yellow colouration. Sulphuric acid with a trace of potassium dichromate yields a red colour, changing to brown, and with a trace of selenious acid gives a light green colour, changing to brown. It should be **stored** in well-stoppered bottles and protected from light.

Soluble in water and alcohol; slightly soluble in chloroform; very slightly soluble in ether

Standard.—Hydrastine hydrochloride loses, on drying at 100° , not more than 6 per cent. of its weight. Ash, not more than 0.1 per cent. No blue fluorescence is produced when 0.1 gramme is dissolved in 10 millilitres of dilute sulphuric acid (limit of hydrastinine), but a blue fluorescence appears on the addition of a few drops of potassium permanganate solution. A solution of 0.1 gramme in 2 millilitres of water is not reddened on the addition of chlorine solution (limit of berberine).

Action and Uses.—Hydrastine hydrochloride resembles narcotine in some respects in its physiological action. Its effects are exerted mainly through the central nervous system, especially exciting the medulla, the most important results being to produce a rise of blood pressure through constriction of small vessels, to depress the heart and slow the heart beat. Hydrastine is used to contract the uterus, and to arrest hæmorrhage by producing constriction of peripheral vessels, but its effect on the uterus is very doubtful. A 10 per cent. w/v aqueous solution may be given hypodermically, in doses of 0.3 to 0.6 millilitre (5 to 10 minims). Solutions for **injection** may be sterilised by heating at 100° for thirty minutes, by tyndallisation, or by filtration. The containers should comply with the tests for limit of alkalinity of glass, and the solution should be stored protected from light.

Dose.—0.016 to 0.06 gramme ($\frac{1}{4}$ to 1 grain)

HYDRASTINA.—Hydrastine, $C_{21}H_{21}O_6N$, occurs as white, glistening prisms, having a very bitter and pungent taste, and melting at about 132° . It gives an alkaline reaction with litmus. Hydrastine is closely related to narcotine, and when oxidised the two substances yield respectively hydrastinine and cotarnine, opianic acid being split off in each case. It gives a yellow colour with sulphuric acid, becoming purple on heating. In the presence of a trace of molybdic acid, sulphuric acid gives a green colour changing to brown. It may be distinguished from hydrastinine by the absence of a blue fluorescence when 1 part is dissolved in 100 parts of dilute sulphuric acid. It is soluble in alcohol (1 in 120), ether (1 in 83), chloroform (1 in 2), and benzene; insoluble in light petroleum and water. Care must be taken not to confuse hydrastine with the extract known as hydrastin. Hydrastine has a similar action to the hydrochloride but, on account of its insolubility, is seldom used. It may be administered in pill form with extract of ergot or hamamelis. **Dose.**—0.016 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

HYDRASTININÆ HYDROCHLORIDUM

(Hydrastinin. Hydrochlor.)

Hydrastinine Hydrochloride*Synonym*—Hydrastinine Chloride.

Hydrastinine hydrochloride is a salt of the alkaloid hydrastinine, which is produced by the oxidation of hydrastine. It occurs in the form of pale yellow, needle-shaped crystals, or as a yellowish-white, crystalline powder, without odour and with a very bitter taste. It melts at about 210° . The strong aqueous solution is pale yellow in colour, and has a blue fluorescence, which becomes more pronounced on further dilution with water; it is optically inactive and is neutral to litmus. Potassium dichromate solution produces a yellow precipitate, which dissolves on heating, but separates again on cooling in yellowish-red, needle-shaped crystals.

Very **soluble** in water and alcohol (1 in 3); sparingly soluble in chloroform, and still less soluble in ether.

Standard.—Hydrastinine hydrochloride leaves not more than 0.1 per cent. of ash. No turbidity is produced on the addition of dilute solution of ammonia to an aqueous solution (1 in 20) (limit of foreign alkaloids), and on the addition of bromine solution to a solution (1 in 20) a yellow precipitate, completely soluble in dilute solution of ammonia, is produced (limit of hydrastine). The addition of 2 to 2.5 millilitres of sodium hydroxide solution to a solution of 0.1 gramme of hydrastinine hydrochloride in 3 millilitres of water produces a white turbidity which, on shaking, entirely disappears; on prolonged shaking or stirring of this solution, or on standing for some time, white crystals of hydrastinine separate, the supernatant liquid remaining clear and almost free from yellow colour (limit of foreign alkaloids).

Action and Uses.—Hydrastinine hydrochloride slows and strengthens the heart's action by direct effect on the muscle. The arterioles are constricted with resulting increase of blood pressure. The most important action, however, is on the uterus, which increases in tone and contracts rhythmically under its influence. It is used to check excessive menstrual loss, but is of little value in post-partum hæmorrhage and is inferior to ergot. Hydrastinine applied to the eye causes dilatation of the pupil. The salt is employed hypodermically in 10 per cent. w/v aqueous solution, in doses of 0.016 to 0.03 gramme ($\frac{1}{4}$ to $\frac{1}{2}$ grain).

Dose.—0.016 to 0.03 gramme ($\frac{1}{4}$ to $\frac{1}{2}$ grain), increased to 0.06 gramme (1 grain).

HYDRASTININA.—Hydrastinine, $\text{C}_{11}\text{H}_{13}\text{O}_2\text{N}$, is obtained by the oxidation of hydrastine in acid solution and purified by recrystallisation from benzene or ethyl acetate. It forms white or faintly yellowish, acicular crystals, having an intensely bitter taste. Melting-point, 116° to 117° . An aqueous solution of hydrastinine is strongly alkaline. It is precipitated from its solution in acids by potassium

hydroxide solution, but not by ammonia or sodium carbonate. Nessler's reagent is instantly reduced by it, with formation of a black precipitate of mercury. This test is said to distinguish it from nearly all other alkaloids. It is readily soluble in alcohol, ether and chloroform, but not in cold water, although moderately soluble in hot water. Dose.—0.016 to 0.03 gramme ($\frac{1}{4}$ to $\frac{1}{2}$ grain), increased to 0.06 gramme (1 grain).

HYDRASTIS

(Hydrast.)

Hydrastis

Synonyms—Golden Seal; Yellow Root; Hydrastis Rhizome; Hydrastis rhizoma I.A.

Hydrastis consists of the dried rhizome and roots of *Hydrastis canadensis* Linn. (Fam. Ranunculaceæ), a small perennial plant, growing in Canada and the Eastern United States; it is collected in the autumn.

The rhizome is small, yellowish-brown and tortuous, from 1 to 6 centimetres long and from 3 to 12 millimetres thick, wrinkled longitudinally and marked by encircling scale-leaf scars. It bears frequent, short, upright branches terminated by cup-shaped scars left by the aerial stems. All parts of the surface bear numerous brittle, curved, wiry roots, which often become partly or wholly broken off, leaving short protuberances or circular, yellow scars. The rhizome is hard, and breaks with a resinous fracture. The transversely cut surface varies in colour from dark yellow to dark yellowish-brown, and exhibits a comparatively thick bark and a ring of about 12 to 20 bright yellow, somewhat distant, narrow, wood bundles surrounding a large pith. The freshly broken surface gives a characteristic bright yellow fluorescence in ultra-violet light. The odour is distinct and disagreeable, and the taste is bitter.

The diagnostic **microscopical** characters are the parenchymatous ground tissue containing numerous starch grains up to 15 microns in diameter, and both simple and compound with 2 to 6 components; the small, lignified, pitted vessels and fibres of the xylem; the brown, tabular-celled cork; the absence of calcium oxalate and of stone cells.

Hydrastis **contains** the alkaloids hydrastine, berberine and canadine. Hydrastine is present to the extent of about 2 per cent., and berberine to the extent of about 2.5 per cent.

Standard.—Hydrastis contains not more than 2 per cent. of foreign organic matter. Acid-insoluble ash, not more than 3 per cent.

Hydrastis, in powder (Pulvis Hydrastis : Pulv. Hydrast.), contains the constituents and possesses the diagnostic microscopical characters of Hydrastis, and complies with the limit for acid-insoluble ash of the unground drug. Pulvis Hydrastidis I.A. contains not less than 2 per cent. of hydrastine.

Action and Uses.—Hydrastis has been used as a simple bitter, presumably because of the large quantity of berberine which it contains. It is used to control excessive uterine hæmorrhage, but its alkaloid, hydrastine, is less useful than hydrastinine in this respect. In post-partum hæmorrhage it is of little value, and is inferior to ergot. It is used in inflammations of the uterine mucosa and in leucorrhœa. Hydrastis is administered in the form of tincture, extract and liquid extract.

Preparations

Elixir Viburni et Hydrastis, B.P.C.—(Elix. Viburn. et Hydrast.)—Elixir of Black Haw and Hydrastis. *Syn.*—Elixir Viburni Compositum; Compound Elixir of Viburnum Prunifolium. Liquid extract of black haw, 1 in 2, and extract of hydrastis, about 1 in 6, with oils of coriander and caraway, and glycerin. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Extractum Hydrastis, B.P.C.—(Ext. Hydrast.)—Extract of Hydrastis. *Syn.*—Hydrastin; Extractum Hydrastis Siccum. A dry alcoholic extract containing from 7.5 to 8.5 per cent. of hydrastine; 0.12 gramme contains about 0.01 gramme, and 2 grains contains about $\frac{1}{4}$ grain, of hydrastine. Dose.—0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains).

Extractum Hydrastis Liquidum, B.P.C.—(Ext. Hydrast. Liq.)—Liquid Extract of Hydrastis. *Syn.*—Extractum Hydrastidis fluidum I.A. An alcoholic extract containing from 1.9 per cent. to 2.1 per cent. of hydrastine; 1 millilitre contains about 0.02 gramme, and 15 minims contains about $\frac{3}{11}$ grain, of hydrastine. Dose.—0.3 to 1 millilitre (5 to 15 minims).

This liquid extract was included in the British Pharmacopœia, 1914.

Tinctura Hydrastis, B.P.C.—(Tinct. Hydrast.)—Tincture of Hydrastis. *Syn.*—Tinctura Hydrastidis I.A. Liquid extract of hydrastis, 1 in 10. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm)

This tincture was included in the British Pharmacopœia, 1914.

HYOSCINÆ HYDROBROMIDUM

(Hyoscin. Hydrobrom.)

Hyoscine Hydrobromide

Synonym—Scopolamine Hydrobromide.

Hyoscine hydrobromide is the hydrobromide of an alkaloid *l*-hyoscine, or *l*-scopolamine, obtained from various solanaceous plants, particularly species of *Datura* and *Scopola*. It occurs in colourless, odourless, transparent crystals with a somewhat bitter, acrid taste. The aqueous solution is neutral or slightly acid to litmus. When a trace of hyoscine hydrobromide is moistened with a few drops of nitric acid, and evaporated to dryness on a water-bath, the residue gives a violet colouration on the addition of alcoholic potassium hydroxide solution. This reaction, which is given also by atropine and hyoscyamine, is masked by the presence of other alkaloids. The alkaloidal base, obtained by extracting the ammoniacal solution with

chloroform, is an oily liquid; when dissolved in hydrochloric acid and a solution of auric chloride added, the yellow gold chloride compound is precipitated in micro-crystals of characteristic form and, when recrystallised from water, it has a melting-point of 198° to 200° . Hyoscine hydrobromide should be **stored** in well-closed containers, in a cool place and protected from light.

Soluble in water (about 1 in 2) and alcohol (90 per cent.) (1 in 13); almost insoluble in chloroform and ether.

Standard, B.P.—Hyoscine hydrobromide, after drying at 100° , has a melting-point of 194° to 196° . Specific rotation, determined on a 5 per cent. w/v aqueous solution of the anhydrous salt, -24° to -26° . Loss, on drying at 100° , not less than 12 per cent. and not more than 13 per cent. Ash, not more than 0.1 per cent. No turbidity is produced on adding solution of ammonia to the aqueous solution, and it complies with a test for absence of other alkaloids, and with a limit test for readily carbonisable substances.

Action and Uses.—The effect of hyoscine in paralysing the parasympathetic nerve endings resembles that of atropine, except that it passes off more rapidly. Hyoscine does not produce the stimulating effect of atropine upon the brain; depression of the motor area is immediate and pronounced. Hyoscine is, therefore, much used as a hypnotic, especially in mania and in cerebral excitement, such as occurs in alcoholism. As a rule, hyoscine produces a sensation of fatigue and drowsiness, which is quickly followed by sleep. In some cases, however, a short stage of excitement and motor unrest precedes sleep, especially if large doses are given. The respiratory centre is not stimulated as by atropine, and collapse has been observed. Hyoscine is much less reliable as a hypnotic than morphine or chloral hydrate. It is most effective when sleep is prevented by motor excitement. The action of hyoscine on the peripheral nerve endings is twice as strong as that of the optically inactive variety; both isomerides act similarly upon the central nervous system.

Hyoscine hydrobromide produces mydriasis and loss of accommodation more quickly, but for a shorter time, than atropine. It is used in 1 per cent. solution or as Oculentum Hyoscinae. As a sedative it is generally **administered** hypodermically, but a solution in chloroform water may be taken by the mouth in chorea and asthma. Its use has been recommended in the treatment of morphine and alcohol addicts, the patient being brought fully under the action of the drug by hypodermic doses of 0.0006 gramme ($\frac{1}{1600}$ grain), repeated if necessary. The use of hyoscine hydrobromide ($\frac{1}{1600}$ grain) with morphine hydrochloride ($\frac{1}{8}$ grain) by hypodermic injection has been recommended previous to operation, when a smaller quantity of general anæsthetic is required and less pain is felt upon recovery of consciousness.

Hyoscine is also used to produce partial anæsthesia in labour; the method which is known as "twilight sleep" depends upon the administration of hyoscine with morphine and the exclusion of all external

disturbing factors. The initial dose of hyoscine hydrobromide is $\frac{1}{150}$ grain with $\frac{1}{8}$ to $\frac{1}{4}$ grain of morphine sulphate. Subsequent injections contain smaller doses of hyoscine and no morphine. Solutions of hyoscine hydrobromide for **injection** are sterilised by tyndallisation or by filtration, and the containers must comply with the tests for limit of alkalinity of glass. In cases of **poisoning** by hyoscine taken by the mouth, the stomach pump should be used, or an emetic given, followed by hot coffee or stimulants. Inhalation of oxygen with 10 per cent of carbon dioxide and artificial respiration may be necessary.

Dose.—0.0003 to 0.0006 gramme ($\frac{1}{3000}$ to $\frac{1}{1000}$ grain).

Preparations

Nebula Hyoscinae Composita, B.P.C.—(Neb. Hyosc. Co.)—Compound Hyoscine Spray. Hyoscine hydrobromide, 0.057 per cent. w/v, cocaine hydrochloride, about 0.9 per cent. w/v, atropine sulphate, about 0.1 per cent. w/v, and sodium nitrite, 12.5 per cent. w/v, in glycerin and distilled water, coloured with solution of bordeaux B.

Oculentum Hyoscinae, B.P.—(Oculent. Hyosc.)—Hyoscine Ointment for the Eye. Hyoscine hydrobromide, 0.125 per cent., in simple eye ointment. It should be stored in small, well-closed containers in a cool place and protected from light.

HYOSCYAMI SEMEN

(Hyoscy. Sem.)

Hyoscyamus Seed

Synonym—Henbane Seed.

Hyoscyamus seed consists of the seeds of *Hyoscyamus niger* Linn. (Fam. Solanaceæ), a herb distributed throughout Europe and extending to Persia and India; it is cultivated for medicinal purposes in England.

The seeds are dark brownish-grey, flattened and sub-reniform, with a slight projection at one point, near to which the hilum is situated, about 1 to 1.2 millimetres in width and 1.5 to 1.75 millimetres long. The surface is covered with small, regular, distinct, raised reticulations about 0.1 millimetre in width, with wavy walls. When cut parallel to the flat surfaces, a strongly curved embryo is seen embedded in an oily endosperm.

Hyoscyamus seed **contains** about 0.05 to 0.1 per cent. of alkaloid, consisting of hyoscyamine with a small proportion of hyoscine (scopolamine). The seed also contains about 20 per cent. of fixed oil.

Standard.—Hyoscyamus seed contains not more than 2 per cent. of foreign organic matter. Ash, not more than 4 per cent.

Action and Uses.—Hyoscyamus seed has been used as a domestic remedy for toothache; the vapour obtained by heating the seed on a

hot plate is applied locally by means of a funnel, or a poultice may be made from the crushed material. Liquor Hyoscyami (Bastich) is a liquid extract of hyoscyamus seed which is used in the same way as tincture of hyoscyamus.

HYOSCYAMINA

(Hyoscyamin.)

Hyoscyamine

Hyoscyamine is the chief alkaloidal constituent of belladonna, hyoscyamus, stramonium and other solanaceous plants. The best source is Egyptian henbane, *Hyoscyamus muticus* Linn. From the total alkaloids of this plant, hyoscyamine may be isolated and purified as the oxalate, the recovered base being finally crystallised from dilute alcohol. It occurs as colourless, glistening, felted needles, or as a white, crystalline powder, without odour, but bitter and acrid to the taste. It is lævorotatory, and is readily racemised to atropine (*dl*-hyoscyamine) in the presence of dilute alkali. 0·05 gramme, dissolved in 5 millilitres of water acidified with hydrochloric acid, yields with auric chloride solution a yellow precipitate which, recrystallised from water acidified with hydrochloric acid, forms brilliant, golden-yellow scales, having when dried, a melting-point of 165° (distinction from atropine and hyoscyne). The picrate crystallises from dilute alcohol in plates, which melt at 165°. 0·01 gramme of the base, evaporated to dryness on a water-bath with 5 drops of nitric acid, leaves a residue which, when moistened with alcoholic potassium hydroxide solution, produces a violet colour. This colour is also given by atropine and hyoscyne (scopolamine), but a red colour is given under these conditions by pseudaconitine. On hydrolysis with acids or alkalis, hyoscyamine is converted into tropine, $\text{C}_8\text{H}_{16}\text{ON}$, and tropic acid, $\text{C}_9\text{H}_{10}\text{O}_3$.

Sparingly **soluble** in water; more soluble in ether; readily soluble in benzene, chloroform and alcohol.

Standard.—Hyoscyamine does not melt below 107°. Specific rotation in alcohol (50 per cent.), not below -21° . Ash, not more than 0·1 per cent

Action and Uses.—Hyoscyamine has an action similar to that of hyoscyamine sulphate.

Dose.—0·0003 to 0·0006 gramme ($\frac{1}{2000}$ to $\frac{1}{1600}$ grain).

DATURINA.—Daturine is a mixture of alkaloids obtained from *Datura Stramonium* Linn. (Fam. Solanaceæ). It consists chiefly of hyoscyamine, with a variable proportion of atropine. It occurs in white, silky crystals and is slightly soluble in water, but freely soluble in alcohol, ether and chloroform. The action of daturine is similar to that of hyoscyamine. It is occasionally used as a mydriatic in ophthalmology. **Dose.**—0·0005 to 0·001 gramme ($\frac{1}{2000}$ to $\frac{1}{1000}$ grain).

HYOSCYAMINÆ HYDROBROMIDUM

(Hyoscyamin. Hydrobrom.)

Hyoscyamine Hydrobromide

Hyoscyamine hydrobromide is the hydrobromide of the alkaloid hyoscyamine. It occurs in white, prismatic crystals with an acrid, bitter taste. It melts at about 152° . The aqueous solution is lævorotatory, and it responds to the identity and distinguishing tests given under Hyoscyamina. It should be **stored** in well-stoppered, amber-coloured bottles.

Very **soluble** in water; soluble in alcohol and chloroform; only sparingly soluble in ether.

Standard.—Hyoscyamine hydrobromide loses, on drying at 100° , not more than 1 per cent. of its weight. Ash, not more than 0.1 per cent. A 5 per cent. solution in water is neutral to litmus, and on the addition of platinic chloride solution no precipitate is produced (limit of most other alkaloids). The solution obtained by dissolving 0.05 gramme in 1 millilitre of sulphuric acid is not coloured more than faintly yellow (limit of readily carbonisable impurities).

Action and Uses.—Hyoscyamine hydrobromide has an action similar to that of hyoscyamine sulphate. Solutions for **injection** may be sterilised by tyndallisation or by filtration. The containers must comply with the tests for limit of alkalinity of glass, and the solution should be stored in a cool place protected from light.

Dose.—0.0003 to 0.0006 gramme ($\frac{1}{1000}$ to $\frac{1}{1600}$ grain).

HYOSCYAMINÆ SULPHAS

(Hyoscyamin. Sulph.)

Hyoscyamine Sulphate

Hyoscyamine sulphate is the sulphate of the alkaloid hyoscyamine. It occurs as a white, deliquescent, crystalline powder, without odour, but with a bitter, acrid taste. The aqueous solution is lævorotatory, and it responds to the identity and distinguishing tests given under Hyoscyamina. It should be **stored** in well-stoppered, amber-coloured bottles.

Soluble in water (2 in 1) and alcohol (1 in 4.5); very slightly soluble in ether and chloroform.

Standard.—Hyoscyamine sulphate does not melt below 203° . Loss, on drying at 100° , not more than 1 per cent. Ash, not more than 0.1 per cent. A 5 per cent. aqueous solution is neutral to litmus.

Action and Uses.—Hyoscyamine is intermediate in its action between atropine and hyoscine. It causes less stimulation of the central nervous system than atropine, and is a weaker sedative and hypnotic than hyoscine (see *Atropina* and *Hyoscinae Hydrobromidum*). It has the same action peripherally as atropine, but is more powerful. Hyoscyamine sulphate is **administered** hypodermically, or given in pills, for mental excitement and insomnia, especially in delirium tremens and mania, but is less reliable than *Hyoscinae Hydrobromidum*. It is used to relieve the tremor, rigidity and excessive salivation in paralysis agitans. Large doses may be necessary. Doses of 0·0006 gramme ($\frac{1}{160}$ grain) are recommended in sea-sickness, hourly, if required; doses as large as 0·006 gramme ($\frac{1}{16}$ grain) may be given in mania. A solution for **injection** may be sterilised by tyndallisation or by filtration.

Dose.—0·0003 to 0·0006 gramme ($\frac{1}{3200}$ to $\frac{1}{1600}$ grain).

DUBOISINÆ SULPHAS.—Duboisine sulphate is a mixture of alkaloidal sulphates obtained from *Duboisia myoporoides* R. Br. (Fam. Solanaceæ), and consists chiefly of hyoscyamine and hyoscine sulphates. It occurs as a very hygroscopic, amorphous, yellowish-white powder, or in granules, and is soluble in water or alcohol. Duboisine sulphate is a sedative hypnotic and mydriatic of variable strength. Its principal use is in ophthalmology; as a mydriatic it is much more powerful than atropine, and is applied in solution (0·2 to 0·5 per cent.) or as an ointment. Dose.—0·00025 to 0·001 gramme ($\frac{1}{4000}$ to $\frac{1}{1000}$ grain).

HYOSCYAMUS

(Hyoscy.)

Hyoscyamus

Synonyms—*Hyoscyami Folia*; Hyoscyamus Leaves; Henbane Leaves.

Hyoscyamus consists of the dried leaves and flowering tops of *Hyoscyamus niger* Linn. (Fam. Solanaceæ), an erect herb distributed throughout Europe and cultivated in England and elsewhere. It should be **stored** in a dry place.

The laminae are pale green in colour, and vary in length up to about 25 centimetres, the lower leaves being stalked and ovate-lanceolate, while the upper leaves are shorter, sessile, and ovate-oblong to triangular-ovate. The margin is coarsely dentate, and the apex acute; the midrib is broad, yellowish and conspicuous. The leaves are covered on both sides with long, soft hairs, many of which secrete a resinous substance, rendering the leaves clammy to the touch. The flowers, which are crowded together, arise in the axils of large, hairy bracts; they have a green, hairy, gamosepalous calyx, a yellow, purple-veined, slightly zygomorphic, gamopetalous corolla. The superior ovary is two-celled, and contains numerous ovules. Hyoscyamus has a strong, characteristic odour, and a bitter, slightly acrid taste.

The diagnostic **microscopical** characters are the wavy walls and smooth cuticle of the epidermal cells; the typical cruciferous stomata on both surfaces; the uniseriate hairs, up to 300 microns in length, of two kinds, some simple and 2 to 4 cells long, but the majority terminating in an oval, multicellular gland; the calcium oxalate crystals in the mesophyll, either single prisms, twin crystals, or clusters of few components; the absence of sclerenchymatous fibres.

Hyoscyamus **contains** the alkaloid hyoscyamine, together with smaller quantities of atropine and hyoscyne (scopolamine). The proportion of alkaloid in the carefully dried leaf varies from 0.045 to 0.14 per cent. In isolated cases, larger yields of alkaloid (up to 0.27 per cent.) have been reported, but these are exceptional. Volatile bases, similar to those in belladonna leaf, are also present.

Varieties.—*Hyoscyamus* occurs both as an annual and as a biennial, and the corresponding leaves are available in commerce. Annual *hyoscyamus* is smaller than the biennial; the leaves are less hairy and less incised and the corolla is not so deeply purple-veined. The commercial drug frequently contains a large proportion of stem. The leaves of the first year's growth of the biennial plant are large, petiolate, and may be up to 30 centimetres or more in length; they are free from admixture with the flowers. Second biennial *hyoscyamus* consists of the flowering tops of the biennial variety. These three varieties are approximately equal in alkaloidal content. Much *hyoscyamus* is imported from the South of France, where it is probably collected from annual plants; it usually contains a larger proportion of stem than the English drug, is less carefully dried, and contains less alkaloid. It has been suggested that much of the foreign *hyoscyamus* is derived from *H. albus* Linn.

Substitute.—Egyptian *hyoscyamus*, from *H. muticus* Linn., may be distinguished from the genuine drug by the elongated-cylindrical fruits and the branched, non-glandular hairs. It often contains a considerable proportion of stout, yellowish stalks, and is used for the production of hyoscyamine (or at: opine), of which it contains from 0.2 to about 1 per cent.

Standard, B.P.—*Hyoscyamus* contains not less than 0.05 per cent. of the alkaloids of *hyoscyamus*, calculated as hyoscyamine. It contains not more than 2 per cent. of foreign organic matter, and not more than 1 per cent. of its stem has a width greater than 5 millimetres. Ash, not more than 20 per cent. Acid-insoluble ash, not more than 12 per cent.

Hyoscyamus, in powder (*Pulvis Hyoscyami* : *Pulv. Hyoscy.*) contains the constituents and possesses the diagnostic microscopical characters of *Hyoscyamus*, and complies with the limits for alkaloids, ash and acid-insoluble ash of the unground drug.

Action and Uses.—*Hyoscyamus* possesses an action similar to that of belladonna, but on account of the hyoscyne which it contains, cerebral excitement is less likely to occur. It is usually **administered** as extract, liquid extract, or tincture, and is used to counteract the griping action of purgatives, such as calomel, aloes, or colocynth. The tincture is given in cystitis and as an antispasmodic in asthma, although it is less reliable for this purpose than tinctures of belladonna and stramonium. In cases of **poisoning** by *hyoscyamus*, the procedure adopted under *Belladonnæ Folium* should be followed.

Dose.—0.2 to 0.4 gramme (3 to 6 grains).

Preparations

Extractum Hyoscyami Liquidum, B.P.—(Ext. Hyoscy. Liq.)—Liquid Extract of Hyoscyamus. It is prepared with alcohol (70 per cent.), concentration being effected under reduced pressure at a temperature not exceeding 60°. It is adjusted to contain 0·05 per cent. w/v of the alkaloids of hyoscyamus, calculated as hyoscyamine (limit, 0·045 to 0·055); 0·4 millilitre contains 0·0002 gramme, and 6 minims contains about $\frac{3}{4}$ grain, of alkaloids. Dose.—0·2 to 0·4 millilitre (3 to 6 minims).

Extractum Hyoscyami Siccum, B.P.—(Ext. Hyoscy. Sicc.)—Dry Extract of Hyoscyamus. It is prepared with alcohol (70 per cent.) and adjusted with hyoscyamus, in fine powder, to contain 0·3 per cent. of the alkaloids of hyoscyamus, calculated as hyoscyamine (limits, 0·27 to 0·33); 0·06 gramme contains 0·00018 gramme, and 1 grain contains about $\frac{3}{4}$ grain, of alkaloids. It should be stored in small, wide-mouthed, well-closed containers in a cool place. Dose.—0·016 to 0·06 gramme ($\frac{1}{4}$ to 1 grain).

Extractum Hyoscyami I.A. is prepared with alcohol (70 per cent.), evaporation being conducted at temperatures below 50°.

Pilula Colocynthis et Hyoscyami, B.P.—(Pil. Colocynth. et Hyoscy.)—Pill of Colocynth and Hyoscyamus. Colocynth, about 12·5 per cent., aloes and scammony resin, of each about 25 per cent., with curd soap, oil of clove, dry extract of hyoscyamus and syrup of liquid glucose. Dose.—0·25 to 0·5 gramme (4 to 8 grains).

Succus Hyoscyami, B.P.C.—(Succ. Hyoscy.)—Juice of Hyoscyamus. The juice expressed from the fresh leaves and flowering tops of *Hyoscyamus niger* Linn., mixed with one-third of its volume of alcohol (90 per cent.). Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tinctura Hyoscyami, B.P.—(Tinct. Hyoscy.)—Tincture of Hyoscyamus. Liquid extract of hyoscyamus, 10 per cent. v/v, in alcohol (70 per cent.). It contains 0·005 per cent. w/v of the alkaloids of hyoscyamus, calculated as hyoscyamine (limits, 0·0045 to 0·0055); 4 millilitres contains 0·0002 gramme, and 1 fluid drachm contains about $\frac{3}{4}$ grain, of alkaloids. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tinctura Hyoscyami I.A. is prepared with alcohol (70 per cent.) from 10 per cent. w/w of hyoscyamus leaf.

ICHTHAMMOL

(Ichtham.)

Ichthammol

Synonym—Ammonium Ichthosulphonate.

Ichthammol consists mainly of the ammonium salts of the sulphonic acids prepared from an oily substance obtained by the destructive distillation of bituminous schists, with ammonium sulphate and water. The schist is composed largely of the remains of fish and marine animals, and yields from 1 to 10 per cent. of oil, which contains about 10 per cent. of sulphur. On treating the oil with sulphuric acid, ichthosulphonic acid is formed, which is neutralised with ammonia to give an impure ammonium ichthosulphonate.

Ichthammol occurs as a blackish-brown, viscous liquid with a strong, characteristic odour. When heated with sodium hydroxide, ammonia is evolved. On the addition of hydrochloric acid to a dilute aqueous

solution, a dark, resinous mass is precipitated. Ichthammol contains, in addition to ammonium ichthosulphonate, about 1 per cent. of volatile oil with a strong, penetrating odour, from 5 to 7 per cent. of ammonium sulphate and about 50 per cent. of water.

Soluble in water; partially soluble in alcohol (90 per cent.) and ether; entirely soluble in a mixture of equal parts of alcohol (90 per cent.) and ether; miscible with glycerin and oils.

Standard, B.P.—Ichthammol contains not less than 10·5 per cent. w/w of organically combined sulphur, calculated on the substance dried at 100°, and not more sulphur in the form of sulphates than one-fourth of the total sulphur. Loss, on drying at 100°, not more than 50 per cent. Residue, on ignition with sulphuric acid followed by re-ignition with sulphuric acid, not more than 0·3 per cent.

Action and Uses.—Ichthammol is a mild antiseptic, and is employed in cutaneous disorders. It may be administered internally or applied externally. Taken internally, it is mildly irritant and antiseptic to the gastro-intestinal tract; it is used in gastro-intestinal catarrh, and in acne, eczema and other skin diseases. It is partially absorbed when applied to the skin, and has a stimulating and mildly irritant action in chronic skin diseases such as acne, furunculosis and eczema. It may be **administered** in capsules, pills, or in solution in glycerin. Aqueous solutions are used as gargles, lotions (5 to 30 per cent.), injections for gonorrhœa and cystitis (1 to 5 per cent.), and pigments (20 to 50 per cent.) which dry on the skin. Gelatin suppositories and pessaries containing ichthammol have been observed occasionally to become insoluble on keeping. Ointments (10 to 50 per cent.) made with hydrous wool fat, or paints prepared with glycerin, are of value, smeared over the inflamed areas, in acute articular rheumatism and in erysipelas. Ichthammol mixed with zinc oxide, or bismuth oxide, or a mixture of zinc oxide and magnesium carbonate, may be used in a dry condition for burns. Mixed with glycerin it is applied on tampons in the treatment of cervicitis. Alkaloids are to some extent **incompatible**, since they form insoluble salts of ichthosulphonic acid.

Dose.—0·3 to 0·6 gramme (5 to 10 grains).

Preparations

Collodium Ichthammolis, B.P.C.—(Collod. Ichtham.)—Ichthammol Collodion. *Syn.*—Ammonium Ichthosulphonate Collodion. Ichthammol, 1 in 8, in simple collodion.

Collodium Ichthammolis cum Æthere, B.P.C.—(Collod. Ichtham. c. Æther.)—Ichthammol Collodion with Ether. *Syn.*—Ammonium Ichthosulphonate Collodion with Ether. Ichthammol, 1 in 4, in ether and simple collodion.

Gelatinum Zinci et Ichthammolis, B.P.C.—(Gelatin. Zinc. et Ichtham.)—Gelatin of Zinc and Ichthammol. *Syn.*—Pasta Zinci et Ichthammolis; Unna's Paste with Ichthammol. Ichthammol, about 2 per cent., with zinc oxide, glycerin, gelatin and distilled water.

Glycerinum Ichthammolis, B.P.C.—(Glycer. Ichtham.)—Glycerin of Ichthammol. *Syn.*—Glycerin of Ammonium Ichthosulphonate, 1 in 10.

Parogenum Ichthammolis, B.P.C.—(Parogen. Ichtham.)—Ichthammol Parogen. *Syn.*—Ichthammol Vasoliment; Ammonium Ichthosulphonate Parogen. Ichthammol, 10 per cent. w/v, in parogen.

Pasta Ichthammolis, B.P.C.—(Past. Ichtham.)—Ichthammol Paste. *Syn.*—Ammonium Ichthosulphonate Paste; Gelatinum Ichthammol; Ammonium Ichthosulphonate Jelly. Ichthammol, about 10 per cent., with gelatin, glycerin and distilled water.

Suppositorium Ichthammolis, B.P.C.—(Supp. Ichtham.)—Ichthammol Suppository. *Syn.*—Ammonium Ichthosulphonate Suppository. Each suppository contains 3 grains of ichthammol in suppository of glycerin.

Unguentum Chrysarobini Compositum, B.P.C.—(Ung. Chrysarob. Co.)—Compound Chrysarobin Ointment. Chrysarobin and ichthammol, of each 5 per cent., and salicylic acid, 2 per cent., in yellow soft paraffin.

Unguentum Ichthammolis, B.P.C.—(Ung. Ichtham.)—Ichthammol Ointment. *Syn.*—Ammonium Ichthosulphonate Ointment. Ichthammol, 10 per cent., in wool fat ointment.

Unguentum Ichthammolis Compositum, B.P.C.—(Ung. Ichtham. Co.)—Compound Ichthammol Ointment. *Syn.*—Compound Ammonium Ichthosulphonate Ointment. Ichthammol, 9 per cent., with precipitated sulphur, zinc oxide, starch, resorcinol, betanaphthol and salicylic acid, in wool fat ointment.

Unguentum Pyrogallolis Compositum, B.P.C.—(Ung. Pyrogall. Co.)—Compound Ointment of Pyrogallol. *Syn.*—Unguentum Acidi Pyrogallici Compositum; Compound Pyrogallic Acid Ointment; Unna's Compound Pyrogallol Ointment. Pyrogallol and ichthammol, of each 5 per cent., and salicylic acid, 2 per cent., in yellow soft paraffin.

ICHTHYOCOLLA

(Ichthyocoll.)

Isinglass

Isinglass is the dried, prepared swimming-bladder of the sturgeon, *Acipenser huso* Linn., and of other species of *Acipenser* (Order Sturiones), found in the Caspian and Black Seas and in the rivers which flow into them. The bladders are removed and cut open; they are then soaked in water, spread out on boards, and the outer, silvery membrane removed by rubbing. They are finally dried and are marketed in various forms.

The drug occurs usually in semi-transparent, iridescent, membranous, whitish, horny or pearly shreds. When soaked in water, it softens, swells and becomes more transparent; it dissolves almost entirely in boiling water. A solution in boiling water, 1 in 50, forms, on cooling, an opalescent jelly. It is insoluble in alcohol, but dissolves in most of the dilute acids and alkalis. With tannic acid it forms an insoluble compound. Isinglass is odourless and has a mucilaginous taste.

Isinglass contains about 80 per cent. of collagen, about 3 per cent. of insoluble membrane, and from 15 to 20 per cent. of moisture. It also contains traces of arsenic, about 0.5 to 1 part per million.

Varieties.—Isinglass prepared in sheets is known as "leaf isinglass," or, if several are folded together before drying, as "book isinglass"; each prepared bladder is sometimes rolled and folded round pegs in the form of a horse-shoe, heart or lyre and then forms "staple isinglass." Russian isinglass, exported from the Caspian and Black Seas, is considered the best; Brazilian isinglass is inferior and may be distinguished by its yellowish or brownish colour.

Substitutes.—Similar substances are made from the swimming-bladders of cod, ling, hake, etc., and are characterised by a higher yield of ash and of substances insoluble in water.

Standard.—Isinglass yields not more than 1 per cent. of ash, and not more than 3 per cent. of water-insoluble matter.

Uses.—Isinglass is used in the preparation of "court plaster" and surgeon's isinglass plaster. A plaster, made from a solution spread upon white felt, is used to remove pressure from corns and bed-sores. It has been used as a nutrient in place of gelatin, and as a "fining" for wines and beers.

IGNATIA

(Ignat.)

Ignatia

Synonyms—Ignatia Amara; St. Ignatius Bean.

Ignatia consists of the dried, ripe seeds of *Strychnos Ignatii* Berg (Fam. Loganiaceæ), a woody, climbing shrub indigenous to Samar and other parts of the Philippine Islands.

The seeds are irregularly ovate and bluntly angular in shape, and measure about 25 millimetres in length and rather less in breadth and thickness; they are very hard, and of a dull brownish or dark grey colour. Patches of the dull ash-grey seed coat are occasionally present, bearing numerous appressed hairs, but the greater part has been rubbed off, disclosing the dark endosperm, which is copious and is usually hollow in the centre, where the embryo, with a small radicle and leafy cotyledons, is found. The seeds are without odour, but have an extremely bitter taste.

The diagnostic **microscopical** characters are the hairs with ribs of thickening, similar to those of *nux vomica*, and with ramified bases, neither the ribs nor the bases being lignified; the polygonal cells of the hypodermis with thickened and pitted walls; the thick-walled cells of the endosperm.

Ignatia **contains** the alkaloids, strychnine and brucine, which are present to the extent of from 2.5 to 3 per cent., rather more than half being strychnine.

Action and Uses.—Ignatia possesses a medicinal action similar to that of *nux vomica*, over which it has no evident superiority. In cases

of **poisoning** by ignatia, the antidotes for strychnine should be administered.

Dose.—0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains).

Preparation

Tinctura Ignatie, B.P.C.—(Tinct. Ignat.)—Tincture of Ignatia. 1 in 10. Dose.—0.3 to 1.2 millilitres (5 to 20 minims).

INDICARMINUM

(Indicarmine.)

Indigo Carmine

Synonym—Sodium Indigotindisulphonate.

Indigo carmine is the disodium salt of indigotin-5 : 5'-disulphonic acid, and may be prepared by the action of sulphuric acid on synthetic or natural indigo, the resulting indigotindisulphonic acid being purified, neutralised with sodium carbonate and the sodium salt precipitated by the addition of sodium chloride; a considerable amount of sodium chloride is carried down by the precipitated indigo carmine. It occurs as an almost odourless, blue powder, or in blue granules, with a coppery lustre and a saline taste. It is precipitated from the aqueous solution by the addition of sodium chloride, while the deep blue colour of the aqueous solution is destroyed by treatment with nitric acid, bromine water, or chlorine water, or by reduction with zinc and sodium hydroxide. On ignition, it leaves a residue of sodium sulphate.

Soluble in water (about 1 in 100); almost insoluble in alcohol.

Standard, B.P.—Indigo carmine contains not less than 90 per cent. of $\text{C}_{16}\text{H}_8\text{O}_8\text{N}_2\text{S}_2\text{Na}_2$, calculated on the substance dried at 100° . Loss on drying at 100° , not more than 10 per cent. Residue on ignition with sulphuric acid, followed by re-ignition with sulphuric acid, not less than 30 per cent. and not more than 40 per cent., calculated on the substance dried at 100° . Arsenic limit, 10 parts per million. Lead limit, 20 parts per million. It complies also with limit tests for insoluble matter and for acidity or alkalinity.

Uses.—Indigo carmine is employed as a test for efficiency of the kidney. It is **administered** intravenously or intramuscularly; the usual dose is 4 millilitres of a freshly prepared 0.4 per cent. solution, but occasionally the dose is increased up to a maximum of 10 millilitres. Solutions for **injection** may be sterilised by heating in an autoclave or by tyndallisation. The colour should appear in the urine in ten minutes or so after injection if the kidneys are functioning properly.

Dose.—0.05 to 0.1 gramme ($\frac{3}{4}$ to $1\frac{1}{2}$ grains), by intramuscular

injection; 0.008 to 0.016 gramme ($\frac{1}{8}$ to $\frac{1}{4}$ grain) by intravenous injection.

Indigo.—Indigo is a colouring matter which may be obtained by the hydrolysis of the glycoside, indican, present in the leafy shoots of various species of *Indigofera*. Natural indigo (Colour Index No. 1247) contains other substances such as indigo gum, indigo brown and indigo red which affect the tint. Most of the indigo of commerce is now obtained synthetically (Colour Index No. 1177). It occurs in the form of brick-shaped cakes or as a dark blue powder. Indigo is insoluble in most solvents and only slightly soluble in hot chloroform, amyl alcohol, carbon disulphide and acetic acid. Indigo was at one time employed in medicine for the treatment of disorders of the nervous system, but its use has been discontinued.

INSULINUM

(Insulin.)

Insulin

Insulin is a preparation containing the specific anti-diabetic principle of the mammalian pancreas, and may be prepared from fresh pancreas, or pancreas which has been stored in the frozen condition, by extraction of the finely divided material with alcohol. The precipitate obtained by adding stronger alcohol is dissolved in water, the active material is separated by adjusting the solution to pH5 to pH6 and the precipitate dried. It may also be separated by adding trinitrophenol and dissolving the product in alcohol containing hydrochloric acid of definite strength; the precipitate obtained by pouring the solution into acetone is collected and dried. *Insulin in Solution* is a solution of the dry powder in acidified water containing an antiseptic to prevent the growth of bacteria. The solution is sterilised by filtration, and packed in sealed glass ampoules containing one dose, in which case no antiseptic need be added, or in suitable glass phials containing several doses; each container is labelled with the number of units per millilitre and the date of manufacture. The solution should be **stored** at a temperature below 20°; it is stable for about eighteen months after manufacture if its reaction lies between pH3 and pH4. *Insulin in Tablet Form* consists of sterile tablets of dry insulin mixed with a neutral substance such as lactose, packed in sterile containers and labelled with the number of units contained in each tablet.

Standard, B.P.—Insulin complies with the tests for sterility, and the solution contains 20 units per millilitre. It is controlled by the regulations made under the Therapeutic Substances Act, 1925. It is assayed biologically by comparing the dose necessary to produce hypoglycæmia in rabbits, or convulsions in mice, with the dose of a standard preparation which will produce the same effects. Suggested details of the method of assay on rabbits are described in the British Pharmacopœia. The standard preparation for Great Britain and Northern Ireland is a quantity of dry, soluble insulin hydrochloride prepared and kept in

the National Institute for Medical Research, London. The unit is the specific activity contained in such an amount of the standard preparation as the Medical Research Council may from time to time indicate as the quantity exactly equivalent to the unit accepted for international use.

Action and Uses.—If the pancreas is removed from a dog or cat, the percentage of sugar in the blood rises and sugar appears in the urine as dextrose; this sugar comes in part from sugar in the food, and in part from the conversion of other substances in the body into dextrose. In consequence of this continual loss of dextrose, the animal loses weight. Acetoacetic acid and β -hydroxybutyric acid are formed in the body as a result of the incomplete combustion of fats, and are excreted in the urine. Their presence may be recognised by the odour of acetone in the urine and in the breath. When these substances are present in the blood in large amount, coma is produced, and death may follow quickly. Insulin, when injected, causes a fall of the blood sugar and, in consequence, stops the loss of sugar in the urine. It also renders possible the complete oxidation of acetoacetic and β -hydroxybutyric acids. The amount of sugar in the blood of a normal individual, fasting (estimated before breakfast), is usually between 80 and 120 milligrams in 100 millilitres; after a carbohydrate meal it may rise to as much as 130 or 170 milligrams. So long as the blood contains less than 180 milligrams of sugar in 100 millilitres (called the renal threshold for sugar) no sugar is eliminated by the kidneys (except in the condition known as renal glycosuria in which the renal threshold for sugar is abnormally low), but above this level sugar appears in the urine. It is generally agreed that a fasting level of over 130 milligrams, with an increase to 200 milligrams or more after a meal, is indicative of true diabetes mellitus.

The chief use of insulin is in the treatment of diabetes mellitus, in which condition there is a lack of the internal secretion of the pancreas. Its administration in adequate doses in this condition keeps the blood sugar within normal limits and thereby prevents glycosuria. With the aid of insulin, patients suffering from severe diabetes are able to take a relatively high proportion of carbohydrate in their diet. Insulin can only be used subcutaneously or intravenously, oral administration being useless. The dose of insulin is regulated by estimation of the patient's blood sugar and by examination of the urine for sugar. The latter method is only a rough guide, since the renal threshold for sugar may be higher than normal in cases of diabetes. The blood sugar control is important for two reasons. Firstly, to find out what is an adequate dose to control the hyperglycæmia and glycosuria and, secondly, to avoid the dangers of hypoglycæmia due to an overdose.

Insulin exerts its maximum effect about four to five hours after injection, and it is at this time that symptoms of over-dosage such as sweating, faintness, irritability and double vision are liable to occur. These symptoms are liable to be induced and aggravated by exercise; patients should be warned of this possibility, and recommended

to carry with them a little cane sugar or barley sugar as an emergency remedy. Doses as a rule are given twice daily, thirty minutes before the principal carbohydrate meals, and a suitable dose with which to commence treatment of a mild case is 5 to 10 units. In diabetic coma, a large dose, 60 to 100 units, should be given in part subcutaneously and in part intravenously. Specimens of urine should be collected, by catheter if necessary, every three hours. If the second specimen, that is, the one obtained six hours after the insulin injection, contains sugar, a further dose of 30 to 50 units should be given. So long as sugar appears in quantity in the urine six hours after the injection of insulin, provided the bladder has been emptied three hours after the injection, more insulin may safely be given. A blood sugar estimation should be made as early as possible in any case of diabetic coma, and as frequently as possible afterwards, since only by this information can the dosage of insulin be safely guided. It should be noted that with vigorous treatment the patient may easily pass into hypoglycæmic coma, without any intermediate return to consciousness. In a suspected case of diabetic coma, when the diagnosis is not certain, dextrose must be administered if it is decided to give insulin. It is important to remember that the treatment of diabetic coma does not begin and end with the administration of insulin. Liquids must be given freely by all available routes, and any eradicable sepsis dealt with immediately. Insulin combined with the administration of dextrose is a useful measure in the treatment of wasting diseases such as exophthalmic goitre, anorexia nervosa, as well as in the liver toxæmias and for the prevention of ketosis following a general anæsthetic. Insulin in solution should be dispensed unless insulin in tablets is specified.

Dose.—5 to 100 units, by subcutaneous injection

iodoform

(Iodof.)

Iodoform

Iodoform is triiodomethane, CHI_3 , and may be obtained by the action of iodine on ethyl alcohol or acetone in the presence of an alkali. It may also be prepared by the electrolysis of a solution of potassium carbonate and potassium iodide in alcohol and water. It occurs as a lemon-yellow powder, somewhat unctuous to the touch, tending to agglomerate, and suitable for mixing with other powders, as powdered crystals remaining powdery and suitable for use with a dredger or insufflator, and as larger crystals which are preferred by some surgeons for application to extensive wounds. It has a characteristic, persistent, disagreeable odour and a sweetish, iodine-like taste. Specific gravity

about 2.0. The powdered form sometimes contains a trace of moisture, and may therefore give turbid solutions with chloroform or carbon disulphide; a short exposure to the air, however, will quickly free it from adherent moisture. Iodoform is soluble in warm alcoholic solution of potassium hydroxide; if the solution is rendered acid by the addition of nitric acid, iodine is precipitated. It should be **stored** protected from light.

Very slightly **soluble** in water and benzene; soluble in alcohol (90 per cent.) (1 in 100), ether (1 in 8), chloroform (1 in 10), glycerin (about 1 in 100), collodion (1 in 10), carbon disulphide (1 in 3), olive oil (1 in 30), and in other fixed and volatile oils.

Standard, B.P.—Iodoform contains not less than 99 per cent. of CHI_3 . Melting-point, 120° to 122° Ash, not more than 0.2 per cent. It complies also with tests for absence of soluble yellow colouring matters and of iodides.

Action and Uses.—Iodoform is used in surgery as an antiseptic for application to wounds. It has very little germicidal power *in vitro*, and it does not destroy pathogenic organisms, although it inhibits their growth. Its beneficial action when applied to wounds appears to be due to its effect in reducing secretion from the wounded surface by hindering the emigration of leucocytes from the blood vessels, and to the fact that iodine is liberated by contact of the iodoform with the organic material of the tissues and secretions; the nascent iodine developed is thus the active agent and, doubtless, it enters at once into combination with proteins, acting as a stimulant and facilitating the absorption of exudation. Iodoform has also some local anæsthetic action. When taken internally, it is partly absorbed as such and partly as iodide, through decomposition. Iodoform enclosed in a glutoid capsule is used as a test of pancreatic efficiency; if the pancreas is active, the capsule dissolves in the intestine, and iodine can be detected in the saliva after about two hours.

Absorption, with symptoms of iodism, sometimes occurs from prolonged or extensive application of iodoform to wounded surfaces. Besides symptoms of iodism, iodoform may produce effects very similar to those of chloroform; the stage of excitement is very prolonged, lasting several hours, and is followed by narcosis. For internal administration, it is prescribed in pills or in capsules, sometimes, if intended for use in phthisis, with oil of eucalyptus and guaiacol. Suppositories, pessaries and bougies may contain oil of eucalyptus to cover the persistent odour; coumarin is also used in ointments or dusting powders for the same purpose.

Glycerinum Iodoformi and Injectio Iodoformi (iodoform, 10 per cent. w/v, mucilage of tragacanth, 20 per cent v/v, in distilled water), well diluted, are used for injection into tuberculous sinuses and as bladder antiseptics. As an application to the throat, nose and ear, Pulvis Iodoformi et Acidi Borici is suitable and is particularly useful in tuberculous laryngitis, when it may be supplemented by the action of

ultra-violet light. **Pigmentum Iodoformi Compositum** is used in surgery for application to moist surfaces such as that of the tongue. **Carbasus Iodoformi** is employed as a surgical dressing. **Pasta Bismuthi et Iodoformi** is used largely as an antiseptic dressing for the treatment of abscesses and wounds; the surfaces are cleaned and smeared with the paste. In cases of **poisoning** by iodoform, sodium bicarbonate should be given freely, followed by alcoholic stimulants and the application of warmth.

Dose.—0·03 to 0·2 gramme ($\frac{1}{2}$ to 3 grains).

IODOPYRROLUM.—Iodopyrrole, or iodol, C_4HNI_4 , is obtained by the action of iodine upon pyrrole in the presence of alcohol. It occurs as a light greyish-brown, almost odourless, crystalline powder. When dissolved in sulphuric acid, it forms a green solution which gradually changes to brown. It is decomposed when heated above 140° , with liberation of iodine. It is almost insoluble in water, but soluble in alcohol (1 in 18), ether (1 in 1·5), chloroform (1 in 150), glycerin (1 in 155) and fixed oils. Iodopyrrole has been used as a substitute for iodoform as a dusting powder in infections of the larynx and also as an ointment containing from 10 to 20 per cent. **Dose.**—0·06 to 0·25 gramme (1 to 4 grains).

Preparations

Carbasus Iodoformi, B.P.C.—(Carbas. Iodof.)—Iodoform Gauze. It contains about 5 per cent. of iodoform.

Glycerinum Iodoformi, B.P.C.—(Glycer. Iodof.)—Glycerin of Iodoform. *Syn.*—Emulsio Iodoformi. 1 in 10.

Oculentum Iodoformi, B.P.—(Oculent. Iodof.)—Iodoform Ointment for the Eye. Iodoform, 4 per cent., in simple eye ointment. It should be stored in small, well-closed containers in a cool place, and protected from light.

An ointment for the eye, prepared with 10 per cent. of iodoform, was included in the British Pharmaceutical Codex, 1923.

Oculentum Iodoformi et Atropinæ, B.P.C.—(Oculent. Iodof. et Atrop.)—Iodoform and Atropine Eye Ointment. Iodoform, about 5 per cent., and atropine sulphate, about 0·1 per cent., in simple eye ointment.

Pasta Bismuthi et Iodoformi, B.P.C.—(Past. Bism. et Iodof.)—Bismuth and Iodoform Paste. *Syn.*—B.I.P.P. Bismuth subnitrate, 25 per cent., and iodoform, 50 per cent., with liquid paraffin.

Pigmentum Iodoformi Compositum, B.P.C.—(Fig. Iodof. Co.)—Compound Iodoform Paint. *Syn.*—Whitehead's Varnish. Iodoform, 10 per cent. w/v, with benzoin, storax and balsam of tolu, in ether.

Pulvis Iodoformi et Acidi Borici, B.P.C.—(Pulv. Iodof. et Acid. Boric.)—Iodoform and Boric Acid Powder. Iodoform, 1 in 4, with boric acid.

Suppositorium Iodoformi, B.P.—(Supp. Iodof.)—Iodoform Suppository. Each suppository contains 0·2 gramme (3 grains) of iodoform.

Unguentum Iodoformi, B.P.C.—(Ung. Iodof.)—Iodoform Ointment. Iodoform, 10 per cent., in simple ointment.

This ointment, prepared with lard instead of simple ointment, was included in the British Pharmacopœia, 1914.

Unguentum Iodoformi et Eucalypti, B.P.C.—(Ung. Iodof. et Eucalyp.)—Iodoform and Eucalyptus Ointment. Iodoform, 2 per cent., and oil of eucalyptus, about 20 per cent., in hard and soft paraffins.

IODOPHTHALEINUM

(Iodophthal.)

Iodophthalein

Synonyms—Sodium Tetraiodophenolphthalein;
Tetraiodophthalein Sodium

Iodophthalein is the di-sodium salt of tetraiodophenolphthalein, and may be prepared by the iodination of phenolphthalein. It occurs as an odourless, blue or blue-violet, crystalline powder with a saline, astringent taste. It darkens in colour when heated, and is decomposed with evolution of vapours of iodine. The aqueous solution is dark blue in colour and dichroic. On the addition of an acid, a pale cream-coloured precipitate of the phthalein is produced; when an excess of sodium hydroxide solution is added, the mixture acquires a purple colour which subsequently disappears.

Soluble in water (1 in 7); slightly soluble in alcohol (90 per cent.)

Standard, B.P.—Iodophthalein contains not less than 85 per cent of phthalein, and the separated phthalein contains not less than 61 per cent. and not more than 62 per cent. of iodine. It complies also with a limit test for free phthalein

Action and Uses.—Iodophthalein taken internally is excreted by the liver into the gall bladder, rendering it opaque to X-rays, the administration thus being an aid to diagnosis. The patient is prepared by purgatives forty hours before the examination, and the salt can be given by mouth or intravenous injection.

For the oral method, the patient is given a fat-free meal in the evening, followed thirty minutes later by a drachm of sodium bicarbonate in water to neutralise free acid in the stomach. After this the salt is given in a solution of 4.25 per cent. citric acid, or in grape or orange juice, and radiographs are obtained fourteen to eighteen hours later.

When the stomach is too irritable to retain the salt, the intravenous method may be used; the dose, usually about 3 grammes for an adult, is dissolved in 40 millilitres of sterilised, triply-distilled water, and is given slowly in one injection warmed to body temperature. The solution must be freshly prepared immediately before use. Care must be taken that there is no extraveneous leakage since the drug is very irritant to the tissues. Adrenaline solution, 1 in 1000, should be kept at hand in case of collapse, when 10 minims should be given subcutaneously. Films are exposed eight, ten and twelve hours later. The solution should be brilliantly transparent and dichroic; the slightest trace of acid will cause a cloudy deposit. A solution for **injection** may be sterilised by tyndallisation or by filtration, and the containers should comply with the tests for limit of alkalinity of glass.

Dose.—0.04 to 0.06 gramme per kilogram of body weight up to 5 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ grain per pound of body weight up to 75 grains); up to 3 grammes (45 grains), by intravenous injection.

IODUM

(Iod.)

Iodine

I = 126.9

Iodine is a solid, non-metallic element, which may be obtained from the mother liquors of Chili saltpetre. The mother liquors contain traces of sodium iodate, from which the iodine is liberated by treatment with sodium pyrosulphite. It may also be obtained from the ashes of seaweed (kelp), in which it occurs as sodium and potassium iodides, by lixiviating and distilling the crude iodides thus obtained with manganese dioxide and sulphuric acid. It is purified by sublimation with potassium iodide; when prepared from kelp, the first portion of the sublimate is liable to contain iodine cyanide.

Iodine occurs in heavy, bluish-black, brittle, rhombic prisms, or in plates having a metallic lustre, a distinctive penetrating odour and an acrid taste. The solution in alcohol, ether, or aqueous solutions of iodides is reddish-brown; in chloroform or carbon disulphide it is violet-coloured. In contact with the skin it produces a deep reddish-brown stain, which may be removed readily by solutions of alkalis or of sodium thiosulphate. Iodine is slowly volatile at ordinary temperatures; on heating, it is completely volatilised, giving off violet-coloured vapours which may be condensed as a bluish-black, crystalline sublimate. One drop of a dilute solution of iodine in potassium iodide gives with a solution of starch a deep blue colour, which disappears on boiling and re-appears on cooling. Iodine should be **stored** in a well-stoppered bottle, or in a glass or earthenware container with a well-waxed bung.

Slightly **soluble** in water; soluble in alcohol (90 per cent.) (1 in 12), ether (1 in 4), chloroform (1 in 30), carbon disulphide (1 in 6) and glycerin (1 in 65); very soluble in concentrated aqueous solutions of potassium iodide.

Standard, B.P.—Iodine contains not less than 99.5 per cent. of I. Residue on volatilisation on a water-bath, not more than 0.05 per cent. It complies also with limit tests for cyanogen and for other halogens.

Action and Uses.—Iodine is absorbed into the circulation through the skin, and appears as iodide in the urine. *Liquor Iodi Simplex* is **administered** in progressive doses in milk in the treatment of chronic rheumatism, in cases of hypothyroidism, and as a preoperative measure in hyperthyroidism. Doses of 0.12 to 0.2 millilitre (2 to 3 minims) of *Liquor Iodi Mitis* are sometimes given to check vomiting, but, even in small doses, preparations containing potassium iodide may cause symptoms of iodism, namely, nasal catarrh, gastric irritation, and lachrymation. Compounds of iodine with sesame oil are administered by hypodermic injection in the treatment of rheumatoid arthritis, pulmonary diseases and syphilis. Intravenous injection of iodine, well-diluted with physiological sodium chloride solution, has been employed in pneumonia and septicæmia. The dose for this

purpose is 0.6 to 1.0 millilitre of *Liquor Iodi Aquosus* in 10 millilitres of physiological sodium chloride solution.

Preparations of iodine are applied **externally** as parasiticides and counter-irritants; strong solutions produce desquamation, or, if repeatedly applied, some degree of vesication. A solution of iodine (2 per cent. in 70 per cent. alcohol) is painted on the skin to procure asepsis at the site of operation; when industrial methylated spirit is used for this preparation it must be free from acetone. Weak solution of iodine is an excellent antiseptic in emergencies for general application to wounds and raw surfaces to prevent sepsis. *Liquor Iodi Fortis* is applied as a paint to destroy tinea and other parasitic fungi, and is used also as a mild and prolonged counter-irritant. If applied to enlarged glands, or joints swollen by chronic inflammation, solutions of iodine cause the absorption of inflammatory products. A stronger tincture of iodine, known as Churchill's tincture of iodine, contains 16.5 per cent. w/v of iodine and 3.3 per cent. w/v of potassium iodide in 25 per cent. v/v of water and alcohol (95 per cent.). *Liquor Iodi Oleosa* is less liable to cause cracking of the skin than a non-oily solution. *Unguentum Iodi*, *Unguentum Iodi Denigrascens* and *Parogenum Iodi* are used as mild counter-irritants for application to chilblains and to reduce swellings. *Collodium Iodi* is used as an application to ringworm, chilblains and swollen glands. *Pigmentum Iodi et Aconiti* is applied to the gums as an antiseptic and anodyne.

For **inhalation**, a few drops of the weak solution are added to hot water, often with the addition of creosote or phenol, and the vapour inhaled in phthisis and chronic bronchitis. *Vapor Iodi Æthereus* is used on the absorbent pad or sponge of an oro-nasal respirator inhaler, and is employed in phthisis and chronic expectoration. *Nebula Iodi Composita*, *Nebula Iodi et Mentholis* and *Pigmentum Iodi Compositum* are useful applications for the throat. Iodine forms a loose compound with starch, and is sometimes administered or applied in this form (*Amylum Iodisatum*, 1 in 20). Colourless preparations of iodine are misnamed, since iodine only becomes decolourised on entering into chemical combination with other bodies, hence the medicinal virtues of iodine as such must be considerably modified. Iodised oils, or iodine in combination with vegetable oils, are used as opaque media in X-ray diagnosis.

Iodine is **incompatible** with alkalis and alkali carbonates, oil of turpentine and most volatile oils, tannin and vegetable astringents. With acetone it forms a pungent and irritating compound. The antidotes to iodine **poisoning** are large draughts of milk, mucilage of starch or wheaten flour mucilage, followed by stimulants, warmth to the extremities, and strychnine hypodermically.

Preparations

Collodium Iodi, B.P.C.—(Collod. Iod.)—Iodine Collodion. Iodine, about 1 in 15, in flexible collodion.

Liquor Iodi Æthereus, B.P.C.—(Liq. Iod. Æther.)—Ethereal Solution of Iodine. *Syn.*—*Tinctura Iodi Ætherea*; Ethereal Tincture of Iodine. Iodine, 1 in 40, in ether.

Liquor Iodi Aquosus, B.P.C.—(Liq. Iod. Aq.)—Aqueous Solution of Iodine. *Syn.*—Lugol's Solution. Iodine, 5 per cent. w/v, and potassium iodide in distilled water. Dose.—0.3 to 0.6 millilitre (5 to 10 minims).

Liquor Iodi Decoloratus, B.P.C.—(Liq. Iod. Decol.)—Decolourised Solution of Iodine. *Syn.*—Tinctura Iodi Decolorata; Decolourised Tincture of Iodine. An ammoniacal alcoholic solution containing ammonium iodide and ammonium iodate equivalent to about 3 per cent. w/v of iodine and 6.25 per cent. v/v of strong solution of ammonia.

Liquor Iodi Fortis, B.P.—(Liq. Iod. Fort.)—Strong Solution of Iodine. *Syn.*—Tinctura Iodi Fortis; Strong Tincture of Iodine. It contains 10 per cent. w/v of iodine (limits, 9.8 to 10.2) and 6 per cent. w/v of potassium iodide (limits, 5.8 to 6.2) in distilled water and alcohol (90 per cent.). It should be stored in well-closed, glass-stoppered bottles.

Solutio iodi spirituosus I.A. is prepared with iodine, 6.5 grammes, potassium iodide or sodium iodide, 2.5 grammes, and alcohol (90 per cent.), 91 grammes.

Liquor Iodi Mitis, B.P.—(Liq. Iod. Mit.)—Weak Solution of Iodine. *Syn.*—Tinctura Iodi Mitis; Weak Tincture of Iodine; Tinctura Iodi; Tincture of Iodine. It contains 2.5 per cent. w/v of iodine (limits, 2.45 to 2.55) and 1.5, per cent. w/v of potassium iodide (limits, 1.45 to 1.55) in distilled water and alcohol (90 per cent.). 2 millilitres contains 0.05 gramme of free iodine and about 0.07 gramme of total iodine; 30 minims contains about $\frac{1}{4}$ grain of free iodine and about 1 grain of total iodine. It should be stored in well-closed, glass-stoppered bottles. Dose.—0.3 to 2 millilitres (5 to 30 minims).

Liquor Iodi Oleosus, B.P.C.—(Liq. Iod. Oleos.)—Oily Solution of Iodine. *Syn.*—Tinctura Iodi Oleosa; Oily Tincture of Iodine. Iodine, 8 per cent. w/v, and castor oil, 16.25 per cent. v/v, in alcohol (90 per cent.).

Liquor Iodi Simplex, B.P.—(Liq. Iod. Simp.)—Simple Solution of Iodine. A solution containing 9 per cent. w/v of total iodine in alcohol (95 per cent.) (limits, 8.8 to 9.2), corresponding approximately to 10 per cent. w/w of total iodine. 1 millilitre contains 0.09 gramme, and 15 minims about $1\frac{1}{4}$ grains, of total iodine. It is of the same strength as Tinctura Iodi (French Codex, 1908). It should be stored in well-closed bottles, in a cool place and protected from light. When stored, the proportion of free iodine decreases owing to interaction with the alcohol. Dose.—0.2 to 1 millilitre (3 to 15 minims).

Nebula Iodi Composita, B.P.C.—(Neb. Iod. Co.)—Compound Iodine Spray. Iodine, 1 per cent. w/v, and phenol, 0.5 per cent. w/v, in light liquid paraffin.

Nebula Iodi et Mentholis, B.P.C.—(Neb. Iod. et Menthol.)—Iodine and Menthol Spray. Iodine, 2 per cent. w/v, and menthol, 4 per cent. w/v, in light liquid paraffin.

Parogenum Iodi, B.P.C.—(Parogen. Iod.)—Iodine Parogen. *Syn.*—Iodine Vasoliment; Linimentum Iodi Petrolatum. Iodine, about 10 per cent. w/v, with oleic acid, liquid paraffin and ammoniated alcohol.

Phenol Iodisatus, B.P.C.—(Phenol Iodisat.)—Iodised Phenol. *Syn.*—Iodised Carbolic Acid. Iodine, 10 per cent. w/v, in liquefied phenol.

Pigmentum Iodi Compositum, B.P.C.—(Pig. Iod. Co.)—Compound Iodine Paint. *Syn.*—Mandl's Paint. Iodine, 1.25 per cent. w/v, with potassium iodide and oil of peppermint, in glycerin.

Pigmentum Iodi et Aconiti, B.P.C.—(Pig. Iod. et Aconit.)—Iodine and Aconite Paint. Weak solution of iodine and strong tincture of aconite, equal parts.

Pigmentum Olei Picis cum Iodo, B.P.C.—(Pig. Ol. Pic. c. Iod.)—Oil of Tár and Iodine Paint. *Syn.*—Pigmentum Picis cum Iodo; Pasta Iodi et Picis; Coster's Paste. Iodine, about 20 per cent. w/v, in rectified oil of tar

Syrupus Iodotannicus, B.P.C.—(Syr. Iodotann.)—Iodotannic Syrup. Iodine and tannic acid, of each 1 per cent. w/w, in syrup and syrup of lemon. Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

Syrupus Iodotannicus cum Phosphate, B.P.C.—(Syr. Iodotann. c. Phosph.)—Iodotannic Syrup with Phosphate. Each fluid drachm contains about $2\frac{1}{2}$ grains of calcium phosphate in iodotannic syrup Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

Unguentum Iodi, B.P.C.—(Ung. Iod.)—Iodine Ointment. Iodine, 4 per cent., potassium iodide and distilled water in simple ointment.

This ointment, prepared with glycerin, 12 per cent. w/w, and lard, 80 per cent. w/w, instead of the distilled water and simple ointment, was included in the British Pharmacopœia, 1914.

Unguentum Iodi Denigrescens, B.P.C.—(Ung. Iod. Denig.)—Non-Staining Iodine Ointment Iodine, 5 per cent., with arachis oil and yellow soft paraffin

Vapor Iodi Æthereus, B.P.C.—(Vap. Iod. Æther.)—Ethereal Inhalation of Iodine. Ethereal solution of iodine, 25 per cent. v/v, phenol, 25 per cent. w/v, and creosote, 12.5 per cent. v/v, in alcohol (90 per cent.).

IPECACUANHA

(Ipecac.)

Ipecacuanha

Synonyms—Ipecacuanhæ Radix; Ipecacuanha Root

Ipecacuanha consists of the dried root of *Cephaelis Ipecacuanha* (Brot.) A. Rich. (Fam. Rubiaceæ), a small plant indigenous to Brazil, and cultivated both there and in Selangor (Federated Malay States), Bengal and Burma. The plant grows in small clumps, and produces fibrous roots, many of which develop a greatly thickened bark containing much starch, the wood remaining small; these enlarged roots are collected and dried.

The root occurs in slender, somewhat tortuous pieces, rarely exceeding 16 centimetres in length or 6 millimetres in thickness, and varying in colour from dark brick-red, partly due to the presence of adhering earth, to dark brown; it shows characteristic annulations, resembling wedge-shaped discs, from one to two millimetres wide, and closely applied to one another; the projecting ridges are rounded. The fracture is short and even. The smoothed transverse surface shows a thick, dark grey bark, usually horny but sometimes starchy, and a small dense wood but no pith. Ipecacuanha has a faint odour and a bitter taste.

The diagnostic **microscopical** characters are the narrow, elongated cork cells; the abundant, thin-walled parenchyma of the bark, mostly filled with starch grains, but including scattered cells containing bundles of acicular crystals of calcium oxalate, 30 to 80 microns long, the starch grains being simple, or more usually compound, individual grains being oval or rounded, and not more than 15 microns in diameter, the compound grains containing from 2 to 5, or up to 8, components; the perforated tracheids, small vessels and fibres of the xylem; the lignified, fibrous parenchyma of the medullary rays and the

xylem parenchyma, many cells of which contain starch; the absence of large vessels, sclerenchymatous cells and phloem fibres.

Ipecacuanha contains the two alkaloids, emetine and cephaeline, and small proportions of psychotrine, methylpsychotrine and emetamine. The root contains, in addition, ipecacuanhic acid, the glycoside, ipecacuanhin, and much starch. The total alkaloid present varies in good samples of the root from 2 to 3 per cent. Of this total alkaloid, about 60 to 70 per cent. is emetine and about 26 per cent. is cephaeline, while psychotrine, methylpsychotrine and emetamine form only about 2 per cent.

Varieties.—The commonest commercial variety is known as Rio ipecacuanha and is imported from Matto Grosso in Brazil. Minas ipecacuanha, from the province of Minas Geraes in Brazil, is similar, but is usually more carefully cleaned. Indian ipecacuanha and Johore ipecacuanha cultivated in the Federated Malay States closely resemble the Rio variety and contain about the same proportion of total alkaloids.

Substitutes.—Cartagena ipecacuanha, which is imported from Colombia, has been attributed to *Psychotria acuminata* Benth. It closely resembles the Rio variety, but is distinguished by its larger size, by the annulations which do not completely encircle the root but take the form of numerous distinct transverse ridges, and by the larger starch grains, which often measure from 17 to 22 microns. Cartagena ipecacuanha contains approximately the same quantity of total alkaloid, of which, however, about 30 to 40 per cent. is emetine. Ipecacuanha stems occur in rather large proportion in some samples of the root; they exhibit no annulations, but are slender and striated longitudinally. They may be distinguished from the root by the presence of a distinct pith, composed of cells with lignified walls; microscopically, they may be identified by the presence of spiral vessels from the xylem and of sclerenchymatous cells. The stem usually contains a smaller proportion of alkaloid than the root. The so-called East Indian ipecacuanha is the rhizome of a small monocotyledonous plant, probably *Cryptocoryne spiralis* Fisch. (Fam. Araceæ), imported from Southern India. It occurs in short pieces up to 5 centimetres long, many of which terminate in a bud and bear encircling leaf-scars; they have a slightly annulated appearance, but are readily distinguished by their monocotyledonous structure and the absence of a central woody core. Lesser striated ipecacuanha is derived from *Manettia ignita* (Vell.) Schum. (Fam. Rubiaceæ); it has a violet-coloured bark and the porous wood contains typical vessels. Greater striated ipecacuanha, from *Psychotria emetica* Mutis (Fam. Rubiaceæ), is similar to the preceding, but contains no starch, it being replaced by sugar in the bark. It possesses a dense wood devoid of large vessels. Undulated ipecacuanha, from *Richardsonia scabra* St. Hil. (Fam. Rubiaceæ), occurs in tortuous pieces which bear transverse lateral fissures; it has a porous wood and a starchy, often violet, cortex. White ipecacuanha, derived from *Hybanthus Ipecacuanha* (Linn.) Baill. (Fam. Violaceæ), is distinguished by its yellowish colour, the absence of annulations, and the porous wood.

Standard, B.P.—Ipecacuanha contains not less than 2 per cent. of the total alkaloids of ipecacuanha, calculated as emetine, of which not less than two-thirds consists of non-phenolic alkaloids, calculated as emetine. It contains not more than 5 per cent. of stems and not more than 1 per cent. of foreign organic matter. Ash, not more than 5.5 per cent.

Ipecacuanha, in powder, contains the constituents, and possesses the diagnostic microscopical characters of Ipecacuanha, and complies with the limits for alkaloids and ash of the unground drug. When

powdered ipecacuanha is prescribed, the standardised powder, *Ipecacuanha Pulverata*, must be used.

Action and Uses.—The properties of ipecacuanha are virtually those of its principal alkaloids, emetine and cephaeline. In small quantity, it is a powerful expectorant, its action lasting several hours. Large quantities are irritant to the whole gastro-intestinal tract, and produce vomiting and diarrhœa. The powdered drug is irritating to the nasal and laryngeal mucous membrane, causing violent sneezing and coughing. *Ipecacuanha* is **administered** as *Ipecacuanha Pulverata*. It is used in small doses as an expectorant in acute and chronic bronchitis, and in cough when secretion is scanty. It is well tolerated by children and is used in croup and whooping cough. Large doses are used for their emetic action, which is exerted in twenty to thirty minutes. Doses of 1 to 4 grammes ($\frac{1}{4}$ to 1 drachm) accompanied by opium if retention is difficult are given in amœbic dysentery. The mode of action of ipecacuanha in this respect is not clearly known.

Ipecacuanha, administered by the mouth, destroys amœbæ on the surface of the bowel wall, and therefore prevents cyst formation, but it does not affect amœbæ in the substance of the bowel wall. Usually 1·3 grammes (20 grains) of powdered ipecacuanha is given at bedtime, sometimes with morphine and tannic acid, and emetine hydrochloride is injected during the day. For children and for general use as an expectorant, *Tinctura Ipecacuanhæ* and *Acetum Ipecacuanhæ* are commonly used. To produce diaphoresis in the treatment of incipient colds, *Pulvis Ipecacuanhæ et Opii* is most suitable in the form of powder, pill, tablet or cachet. For this purpose and for use in acute dysentery, powdered ipecacuanha freed from emetine has been recommended, but the untreated drug is preferable. Lozenges of ipecacuanha and of ipecacuanha with morphine, and pills of ipecacuanha and squill, are prepared for use in cough. *Vinum Ipecacuanhæ* of the British Pharmacopœia, 1914, was prepared by mixing 5 parts of liquid extract of ipecacuanha with 95 parts of sherry, setting aside for forty-eight hours and filtering.

Preparations

Acetum Ipecacuanhæ, B.P.C.—(*Acet. Ipecac.*)—Vinegar of *Ipecacuanha*. Liquid extract of ipecacuanha, 1 in 20, with alcohol, acetic acid and water. It contains approximately 0·1 per cent. of the alkaloids of ipecacuanha and is of the same strength as *Tinctura Ipecacuanhæ*. Dose.—0·6 to 2 millilitres (10 to 30 minims).

Elixir Ipecacuanhæ, B.P.C.—(*Elix. Ipecac.*)—Elixir of *Ipecacuanha*. Liquid extract of ipecacuanha, 1 in 20, with alcohol (90 per cent.), glycerin, simple elixir and distilled water. Dose.—0·6 to 2 millilitres (10 to 30 minims).

Extractum Ipecacuanhæ Liquidum, B.P.—(*Ext. Ipecac. Liq.*)—Liquid Extract of *Ipecacuanha*. It is prepared with alcohol (90 per cent.), concentration being effected under reduced pressure at a temperature not exceeding 60°. It is adjusted to contain 2 per cent. w/v of the total alkaloids of ipecacuanha, calculated as emetine (limits, 1·9 to 2·1); 0·12 millilitre contains 0·0024 gramme, and 2 minims contains about $\frac{1}{25}$ grain, of the total alkaloids of ipecacuanha, calculated as emetine. Dose.—0·03 to 0·12 millilitre ($\frac{1}{4}$ to 2 minims). Emetic dose.—0·6 to 2 millilitres (10 to 30 minims).

Ipecacuanha Pulverata, B.P.—(*Ipecac. Pulverat.*)—Powdered *Ipecacuanha*.

Syn.—Powdered *Ipecacuanha* Root; *Pulvis Ipecacuanhæ*. *Ipecacuanha*, reduced to a fine powder and adjusted with lactose, or with *ipecacuanha* of suitable alkaloidal content, to contain 2 per cent. of the total alkaloids of *ipecacuanha*, calculated as emetine (limits, 1·9 to 2·1), of which not less than two-thirds consists of non-phenolic alkaloids, calculated as emetine. 0·12 gramme contains 0·0024 gramme, and 2 grains contains about $\frac{1}{8}$ grain, of the total alkaloids of *ipecacuanha*, calculated as emetine. Ash, not more than 5·5 per cent. It should be stored in well-closed containers. Dose.—0·03 to 0·12 gramme ($\frac{1}{4}$ to 2 grains); emetic dose, 1 to 2 grammes (15 to 30 grains).

Pulvis Ipecacuanhæ I.A. contains 2 per cent. of total alkaloids.

Linctus Diamorphinæ cum Ipecacuanha, B.P.C.—(*Linct. Diamorph. c. Ipecac.*)—

Linctus of Diamorphine with *Ipecacuanha*. Each fluid drachm contains $\frac{1}{10}$ grain of diamorphine hydrochloride and $\frac{1}{4}$ minim of liquid extract of *ipecacuanha*, with tincture of hyoscyamus, spirit of chloroform, syrup of tolu, syrup of wild cherry and glycerin. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Mistura Ipecacuanhæ Composita, B.P.C.—(*Mist. Ipecac. Co.*)—Compound

Ipecacuanha Mixture. *Syn.*—*Mistura Expectorans*. Each fluid ounce contains 24 minims of vinegar of *ipecacuanha*, 15 minims of strong solution of ammonium acetate and 15 minims of oxymel of squill, with glycerin and chloroform water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Pilulæ Ipecacuanhæ cum Scilla, B.P.C.—(*Pil. Ipecac. c. Scill.*)—*Ipecacuanha*

Pills with Squill. Each pill contains 2 grains of powder of *ipecacuanha* and opium, and $\frac{1}{4}$ grain each of squill and ammoniacum. Dose.—1 or 2 pills.

The mass with which these pills are made was included in the British Pharmacopœia, 1914, under the name of Pilula Ipecacuanhæ cum Scilla.

Pulvis Ipecacuanhæ et Opii, B.P.—(*Pulv. Ipecac. et Opii.*)—Powder of *Ipecacuanha*

and Opium. *Syn.*—*Pulvis opii et Ipecacuanhæ compositus* I.A.; *Pulvis Ipecacuanhæ Compositus*; Compound Powder of *Ipecacuanha*; Dover's Powder. Powdered *ipecacuanha* and powdered opium, of each 10 per cent., with lactose. It contains 1 per cent. of anhydrous morphine (limits, 0·95 to 1·05); 0·6 gramme contains 0·006 gramme, and 10 grains contains $\frac{1}{10}$ grain, of anhydrous morphine. Dose.—0·3 to 0·6 gramme (5 to 10 grains).

Syrupus Ipecacuanhæ, B.P.C.—(*Syr. Ipecac.*)—Syrup of *Ipecacuanha*. Vinegar of *ipecacuanha*, 1 in 2, with sucrose and distilled water. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Sirupus Ipecacuanhæ I.A. contains 10 per cent. of *Tinctura Ipecacuanhæ* I.A.

Tabellæ Acidi Acetylsalicylici et Opii, B.P.C.—(*Tab. Acid. Acetylsalicyl. et Opii*)—

Tablets of Acetylsalicylic Acid and Opium. *Syn.*—Tablets of Aspirin and Dover's Powder. Each tablet contains 2½ grains of acetylsalicylic acid and 2½ grains of powder of *ipecacuanha* and opium. Dose.—1 to 3 tablets.

Tabellæ Acidi Acetylsalicylici et Opii Compositæ, B.P.C.—(*Tab. Acid. Acetylsalicyl. et Opii Co.*)—

Compound Tablets of Acetylsalicylic Acid and Opium. Each tablet contains 3 grains of acetylsalicylic acid, 1½ grains of phenacetin and 1 grain of powder of *ipecacuanha* and opium. Dose.—1 to 4 tablets.

Tabellæ Aloini Compositæ, B.P.C.—(*Tab. Aloin. Co.*)—Compound Aloin

Tablets. Each tablet contains $\frac{1}{2}$ grain of aloin, $\frac{1}{2}$ grain of *ipecacuanha* and $\frac{1}{2}$ grain of dry extract of *nux vomica*. Dose.—1 or 2 tablets.

Tinctura Ipecacuanhæ, B.P.—(*Tinct. Ipecac.*)—Tincture of *Ipecacuanha*.

Liquid extract of *ipecacuanha*, 5 per cent. v/v, in alcohol (90 per cent.), glycerin and distilled water. It contains 0·1 per cent w/v of the total alkaloids of *ipecacuanha*, calculated as emetine (limits, 0·095 to 0·105); 2 millilitres contains 0·002 gramme, and 30 minims contains about $\frac{1}{8}$ grain, of alkaloid. Tincture of *ipecacuanha* replaces *Vinum Ipecacuanhæ*, *Ipecacuanha* Wine, of the British

Pharmacopœia, 1914, and contains the same proportion of liquid extract. When Vinum Ipecacuanhæ or Ipecacuanha Wine is prescribed or demanded, Tinctura Ipecacuanhæ must be dispensed or supplied. Doses.—0·6 to 2 millilitres (10 to 30 minims); emetic dose, 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce)

Tinctura Ipecacuanhæ I.A. is prepared with alcohol (70 per cent.) and contains 0·2 per cent. of total alkaloids.

Trochisci Ipecacuanhæ, B.P.C.—(Troch. Ipecac.)—Ipecacuanha Lozenges. Each lozenge contains $\frac{1}{4}$ grain of powdered ipecacuanha

This lozenge, containing 0·015 gramme of powdered ipecacuanha, was included in the British Pharmacopœia, 1914.

Trochiscus Morphine et Ipecacuanhæ, B.P.—(Troch. Morph. et Ipecac.)—Lozenge of Morphine and Ipecacuanha. *Syn.*—Morphine and Ipecacuanha Lozenge. Each lozenge contains approximately 0·002 gramme or $\frac{1}{2}$ grain of morphine hydrochloride and approximately 0·006 gramme or $\frac{1}{10}$ grain of powdered ipecacuanha.

IPOMŒA

(Ipom.)

Ipomœa

Synonyms—Ipomœæ Radix; Orizaba Jalap Root; Mexican Scammony Root; Male Jalap; Stalk Jalap.

Ipomœa is the dried root of *Ipomœa orizabensis* (Pellet.) Ledanois. (Fam. Convolvulacæ), a climbing plant indigenous to the Mexican Andes.

The large, tuberous roots are 18 to 25 centimetres long and 9 to 10 centimetres at the widest part; they are cylindrical-fusiform, grey-brown or brownish-black, and strongly wrinkled longitudinally. The entire roots sometimes occur in commerce, and are often deeply incised longitudinally. More commonly, the tubercles are cut into transverse slices or wedge-shaped pieces, from about 1 to 4 centimetres thick and 5 to 8 centimetres wide; the transverse surface of the slices is earthy-grey, and exhibits irregular concentric circles of pale brown, projecting, fibrous vascular strands. The dried slices are very hard and tough, and break transversely with difficulty, the fracture being short, resinous and irregular. The odour is slight, and the taste resinous and acrid.

The diagnostic **microscopical** characters are the abundant starch grains, mostly muller-shaped components of compound grains, which possess 2 to 5 components, a few rounded grains, the hilum, being central, and individual grains measuring up to 35 microns; numerous cluster-crystals of calcium oxalate, about 15 to 45 microns in diameter; occasional prisms of calcium oxalate; numerous fibres and vessels with bordered pits; greyish-brown resin cells which stain deep yellow with iodine water.

Ipomœa **contains** from about 10 to 20 per cent. of resin, of which a variable proportion (60 to 95 per cent.) is soluble in ether. On hydrolysis

the resin yields dextrose, methylpentose, jalapinolic acid, and methyl-jalapinolate and appears, therefore, to consist mainly of the glycoside and methylpentoside of jalapinolic acid and its methyl ester. It also contains β -methylæsculetin, dihydroxycinnamic acid, fatty acids, phytosterol, starch, calcium oxalate, etc. Boiled with potassium hydroxide solution, the resin is dissolved, but is not reprecipitated on acidifying the solution.

Standard, B.P.—Ipomœa, yields to alcohol (90 per cent.) a resin which after washing with water, has the properties described under Scammonia Resina.

Ipomœa, in powder (Pulvis Ipomœæ : Pulv. Ipom.), contains the constituents and possesses the diagnostic microscopical characters of Ipomœa, and complies with the standard for the unground drug.

Action and Uses.—Ipomœa is a drastic purgative, and is usually administered in the form of its resin.

Dose.—0.3 to 1.2 grammes (5 to 20 grains).

SCAMMONIÆ RADIX.—Scammony root consists of the dried root of *Convolvulus Scammonia* Linn. (Fam. Convolvulaceæ), a climbing plant indigenous to the Eastern Mediterranean. The root is brownish-grey or yellowish-grey, hard, heavy and woody. It is sub-cylindrical or slightly tapering, varying from 2 to 10 centimetres in diameter and 15 centimetres to 1 metre in length, often spirally twisted, contorted, longitudinally furrowed, and crowned with the short remains of numerous aerial stems; the fracture is very coarsely fibrous. The smoothed, transversely cut surface is light in colour and exhibits numerous more or less circular cambia with porous xylem internally and phloem externally, the phloem being dotted with resin cells, which appear as dark points under a pocket lens; the parenchymatous tissue, in which these structures are embedded, contains abundant starch. The starch of scammony root is in small grains, which are usually compound (two, three, or four constituents); the isolated, component starch grains are conical or muller-shaped, and usually exhibit a V-shaped, or radiately cleft, hilum; the large grains measure about 20 to 25 microns. The odour is characteristic, and the taste is sweetish and slightly acid. The root contains from 3 to 13 per cent. (average about 8 per cent.) of resin together with dihydroxycinnamic acid, β -methylæsculetin, ipuranol, sucrose, a reducing sugar and starch. The resin consists mainly of the glycosides and methylpentosides of jalapinolic acid and its methyl ester; it is hydrolysed by caustic alkali, with the production of jalapinolic, methylbutyric, tiglic, formic and other acids, together with rhamnose: it is almost entirely soluble in ether. Scammony root is now rarely used except for preparing scammony (Scammonium), scammony resin (Scammonia Resina) being now obtained from Ipomœa.

IRIDIS RHIZOMA

(Irid. Rhiz.)

Orris

Synonym—Orris Root.

Orris consists of the rhizome of *Iris germanica* Linn., *I. pallida* Lam. and *I. florentina* Linn. (Fam. Iridaceæ), all of which are cultivated in Italy. The rhizomes are collected in the late summer, freed from the roots, growing portions, etc., peeled and slowly dried.

The rhizome occurs usually in hard and compact pieces from 5 to 10 centimetres long and about 2 to 3 centimetres wide. It is pale cream in colour, slightly flattened dorsiventrally, and exhibits enlargements and contractions, each enlargement representing one year's growth; one or two short branches are usually attached to the larger extremity. The under surface bears numerous conspicuous, circular root-scars, and the upper surface indistinct leaf-scars, or traces of the fibrovascular bundles which have passed from leaf to rhizome. The smoothed transverse surface shows a comparatively narrow cortex, separated by a brownish endodermis from the large stele, which is pale cream in colour, and exhibits numerous scattered vascular bundles, and here and there small, shining crystals of calcium oxalate. The fresh rhizome is almost odourless, the characteristic odour developing during the drying process and subsequent storage.

The diagnostic **microscopical** characters are the abundant starch grains, mostly simple, about 25 to 30 microns long and 10 to 25 microns wide, oval or elliptical in outline, and with a distinct, radiate hilum; large prismatic crystals, about 250 by 30 microns, of calcium oxalate; thick-walled parenchymatous tissue; the absence of bast-fibres.

Orris contains a volatile substance, known as concrete oil of orris, or butter of orris, 0.1 to 0.2 per cent., pale yellow, and solid at ordinary temperatures (melting-point, about 40°), and composed of about 85 per cent. of myristic acid, the remaining 15 per cent. being a mixture of irone, oleic acid, methyl myristate, and other esters. Irone, $C_{13}H_{20}O$, is an oily liquid with a pungent odour, quite distinct from that of violets until largely diluted. The rhizome also contains a crystalline glycoside, iridin (which must be distinguished from the resinoid, iridin, obtained from iris), abundance of starch, and a little resin. The ash of orris is usually from 2 to 4 per cent.

Varieties.—The finest variety, Florentine orris, occurs in bold, pale coloured, carefully peeled pieces of very fragrant odour. Verona orris occurs in thinner, less carefully peeled pieces, slightly darker in colour, many pieces having a hole at one end by which they have been suspended during the drying process. The odour is not so fragrant as that of the Florentine variety.

Substitutes.—Mogador orris is much darker in colour than Italian orris, and exhibits portions of reddish cork and the remains of buds. Indian orris is small, generally unpeeled, and has little aroma.

Action and Uses.—In large doses, orris acts as a cathartic. The powder is a common ingredient of toilet powders and is occasionally used in dental preparations. Pieces of the rhizome are given to infants to bite on in order to assist dentition. The volatile oil of orris is extensively used for blending with ionone as a base for violet perfumes. A syrup commonly known as "syrup of violets" (*Syrupus Violæ*) is usually prepared from tincture of orris and coloured with a violet dye.

IONONUM.—Ionone is a mixture of two isomeric ketones, α and β , of the formula $C_{13}H_{20}O$, obtained from citral or oil of lemon grass by condensation with acetone in the presence of an alkali, the pseudo-ionone so produced being treated with sulphuric acid. The commercial product varies somewhat in odour and other

properties according to the proportion of the two isomers present. When pure it occurs as a colourless liquid, but in commerce it is usually greenish-yellow. It has a specific gravity of about 0.935 and a boiling-point of about 126° under 10 mm. pressure. When well diluted it has a powerful violet-like odour. Ionone gives an intense golden-yellow colouration on treatment with hydrochloric acid, the colour changing to dirty violet on adding chloral hydrate and heating. The violet colour is destroyed on shaking the cold liquid with ether. Ionone and other related compounds, such as methyl-ionone, are largely used in perfumery.

METHYLHEPTINÆ CARBONAS.—Methylheptine carbonate, $\text{CH}_3(\text{CH}_2)_4\text{C} \cdot \text{C} \cdot \text{COOCH}_3$, may be prepared synthetically from the ricinoleic acid occurring in castor oil. It occurs as a colourless, mobile liquid, having a specific gravity of about 0.952 and a boiling-point of 107° under 20 mm. pressure. When pure it has a strong, penetrating, disagreeable odour but when highly diluted it has a fine, persistent violet-like odour. Methylheptine carbonate and other compounds of somewhat similar composition are used in perfumery.

IRIS

(*Iris*)

Iris

Synonym—Blue Flag.

Iris consists of the dried rhizome and roots of *Iris versicolor* Linn. (Fam. Iridaceæ), a herbaceous perennial growing in marshy ground in Eastern and Central North America.

The drug occurs in pieces usually from 5 to 20 centimetres long and 1 to 2.5 centimetres thick, cylindrical in the older part, but for the most part flattened dorsiventrally and divided by slight constrictions, about 3 to 5 centimetres apart, into more or less enlarged portions. Externally it is reddish-brown, wrinkled longitudinally, and bears annular markings; the lower surface shows very numerous root-scars, or, occasionally, transversely wrinkled roots; the upper surface bears leaf-scars. The fracture is short, varying in colour from cream to purplish-brown, and exhibits pale fibrovascular bundles scattered throughout the stele. The odour is slight, and the taste pungent and acrid.

Iris contains a resinoid, iridin (which must be distinguished from the glycoside, iridin, contained in *Iris florentina* Linn.), isophthalic acid and a trace of salicylic acid; small amounts of starch and tannin are also present. The rhizome yields to alcohol (60 per cent.) about 25 per cent. of extractive.

Action and Uses.—*Iris* exerts a cathartic action and is given in the form of extract, frequently in combination with euonymin or papain.

Preparations

Extractum Iridis, B.P.C.—(Ext. Irid.)—Extract of *Iris*. *Syn.*—Iridin; Extractum Iridis Siccum. The alcoholic percolate evaporated to dryness and mixed with calcium phosphate. Dose.—0.06 to 0.2 gramme (1 to 3 grains).

Liquor Euonymini et Iridini, B.P.C.—(Liq. Euonym. et Iridin.)—Solution of Euonymin and Iridin. It contains the equivalent of about 3·5 per cent. w/v of extract of euonymus and about 2 per cent. w/v of extract of iris, with potassium carbonate, distilled water and alcohol (45 per cent.) Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Liquor Papaini et Iridini, B.P.C.—(Liq. Papain. et Iridin.)—Solution of Papain and Iridin. Each fluid drachm contains 1 grain each of papain and extract of iris, with glycerin, alcohol (90 per cent.) and chloroform water. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

ISPAGHULA

(Ispagh.)

Ispaghula

Synonyms—Spogel Seeds; Isafgul.

Ispaghula consists of the dried, ripe seeds of *Plantago ovata* Forsk. (Fam. Plantaginaceæ), a herbaceous annual indigenous to India and Persia.

The seeds are about 1 to 3·5 millimetres long and 1 to 1·75 millimetres wide, ovate in outline and boat-shaped; they are hard and pinkish-buff, and have a reddish-brown oval spot, about one-quarter of the length of the seed, in the centre of the convex surface; occasional seeds are uniformly reddish-brown in colour. The hilum appears as a brown spot in the centre of the hollow, which is more or less covered with a whitish membrane having two perforations, one on each side of the hilum. The endosperm is hard, and the straight embryo, which is almost as long as the seed, lies near the convex surface, and has two cotyledons with their contiguous, flattened, upper surfaces in the median plane. The epidermis is mucilaginous, and swells in water to form a translucent, colourless envelope to each seed. The taste is mucilaginous, and the odour is not marked.

The diagnostic **microscopical** characters are the polygonal cells of the epidermis, which are transparent and filled with mucilage; the thick, cellulose-walled cells of the endosperm, with numerous pits and granular contents; the thin-walled, polyhedral cells of the embryo containing fixed oil and aleurone grains.

Ispaghula **contains** mucilage as the chief constituent, and also protein, fixed oil, etc. It yields about 2·5 per cent. of ash.

Standard.—Ispaghula contains not more than 3 per cent. of foreign organic matter. One hundred seeds weigh not less than 0·17 gramme and not more than 0·22 gramme. 1 gramme, agitated gently and occasionally during twenty-four hours in a 25 millilitre stoppered-cylinder filled to the 20 millilitre mark with water, and allowed to stand for one hour, occupies a volume of not less than 10 millilitres.

Ispaghula, in powder (Pulvis Ispaghulæ : Pulv. Ispagh.), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—Ispaghula, when moistened with water, swells into a gelatinous mass, a property which has given rise to its use in the treatment of atony of the intestine with constipation. In the treatment of chronic diarrhœa, ispaghula may be given dry, or in the form of a decoction (Decoctum Ispaghulæ, 1·5 in 100), in doses of $\frac{1}{2}$ to 2 fluid ounces.

Dose.—3 to 10 grammes (45 to 150 grains).

ISPAGHULÆ TESTA.—Ispaghula husk consists of the epidermis removed from ispaghula. It is composed of small, transparent, colourless, brittle flakes which swell rapidly in water. Ispaghula husk contains mucilage, small traces of starch and cellulose. It is used for the same purposes as the whole seeds, but is more powerful in its action.

JABORANDI

(Jaborand.)

Jaborandi

Synonyms—Pilocarpus; Jaborandi Leaves.

Jaborandi consists of the dried leaflets of *Pilocarpus microphyllus* Stapf (Fam. Rutacæ), a shrub indigenous to Brazil, and bearing imparipinnate leaves; it is exported from Maranham.

The leaflets are dull greenish-brown in colour, 2·5 to 4 centimetres long, punctate, obovate and asymmetrical. The margin is entire, the apex emarginate, and the base unequal; the terminal leaflets are symmetrical, with an equal base. The odour of the leaflets, when crushed, is aromatic; the taste is pungent and aromatic and, when the drug is chewed, salivation is induced.

The diagnostic **microscopical** characters are the polygonal, straight-walled, epidermal cells, the cuticle on the upper side being strongly striated; stomata on the lower surface only, each stoma being surrounded by four or five tangentially-arranged cells; occasional groups of smaller epidermal cells, which mark the insertion of inconspicuous external glands; the large, schizo-lysigenous oil glands of the mesophyll; the single layer of palisade; the cluster-crystals of calcium oxalate; the occasional, conical, thick-walled, protective hairs.

Jaborandi **contains** the alkaloids, pilocarpine, isopilocarpine and pilosine, and volatile oil which has a powerful odour, recalling that of rue. Pilocarpine occurs in variable quantity, but rarely more than 0·5 per cent.

Substitutes.—The leaflets of *Pilocarpus Jaborandi* Holmes, Pernambuco jaborandi, were formerly official, but are now seldom imported. They may be distinguished by their large size, being up to 10 centimetres long; the margin is revolute and the base mostly unequal. Numerous other substitutes occur, amongst which are the leaflets of the following plants:—*P. pennatifolius* Lem., Paraguay jaborandi, official in 1885, distinguished by their greyish-green colour, length of 10 centimetres or more, less coriaceous texture, nearly equal base and small alkaloidal content; *P. Selloanus* Engler, Rio Janeiro jaborandi,

characterised by the more distinctly obovate shape; *P. trachylophus* Holmes, Ceara jaborandi, olive-green in colour, with recurved margin and abundant, short, curved hairs on the under surface; *Swartzia sp.* (Fam. Leguminosæ), the leaflets of which are distinguished by the absence of oil glands.

Standard.—Jaborandi contains not more than 5 per cent. of stalks, stems and other foreign organic matter.

Action and Uses.—Preparations of jaborandi stimulate all parasympathetic nerve endings, produce broncho-constriction, increase secretion of sweat and saliva, and cause contraction of the uterus and augmentation of the movements of the gut. Preparations are occasionally added to hair lotions for their supposed effect in promoting the growth of the hair. In case of **poisoning**, atropine should be injected hypodermically, or tincture of belladonna given by the mouth.

Preparations

Extractum Jaborandi Liquidum, B.P.C.—(Ext. Jaborand. Liq.)—Liquid Extract of Jaborandi. 1 in 1.

Tinctura Jaborandi, B.P.C.—(Tinct. Jaborand.)—Tincture of Jaborandi. Liquid extract of jaborandi, 1 in 5. Dose.—0·6 to 2 millilitres (10 to 30 minims).

JALAPA

(Jalap.)

Jalap

Jalap consists of the dried tubercles of *Ipomœa purga* Hayne (Fam. Convolvulacæ), a climbing plant indigenous to the eastern slopes of the Mexican Andes. The tubercles are dried in nets over a fire, the larger ones being cut up or incised longitudinally to facilitate the process.

The drug occurs as hard, heavy, dark brown tubercles, which are usually fusiform or napiform, and from about 3 to 15 centimetres long and 1·8 to 10 centimetres wide at the broadest part, the larger ones usually showing deep and wide incisions; more rarely the larger tubercles are cut into slices or irregular pieces. Externally, the tubercles are furrowed and wrinkled, and marked with numerous small, transverse lenticels. The smoothed transverse surface is yellowish-grey to dull brown in colour, and shows a complete ring of cambium near the outer margin and, within this ring, a number of irregularly arranged tertiary cambia, forming isolated rings and arcs or curving lines. The taste is at first sweet, but afterwards acrid and disagreeable, and the odour is characteristic.

The diagnostic **microscopical** characters are the abundant, thin-walled parenchyma of the general ground tissue, containing starch in compound grains of 2 to 6 components, and also to some extent in simple grains, individual grains measuring up to 60 microns in diameter, being commonly 30 microns; the xylem vessels with numerous bordered

pits; the numerous secretion cells of the phloem, the yellowish-brown contents of which stain yellow with solution of iodine and red with tincture of alkanna; the cluster-crystals of calcium oxalate, about 10 to 30 microns in diameter; the presence of occasional stone-cells and the absence of fibres.

Jalap contains resin, from about 9 to 18 per cent., sugar and starch, together with protein, calcium oxalate, etc. The ether-soluble portion of the resin of jalap is very similar to the ether-soluble portion of the resin obtained from scammony root and from ipomœa, and has been designated scammonin (orizabin). The portion insoluble in ether is jalapin, which has also been termed convolvulin, or jalapurgin. The resin is a very complex mixture; boiled with solution of potassium hydroxide it dissolves, forming the potassium salts of various water-soluble acids (formic, *d*-methylethylacetic, etc.), and when the solution is acidified the resin is not reprecipitated. Boiling with a mineral acid converts it partly into convolvulinolic (hydroxypentadecylic) and ipurolic acids and dextrose; the resin, therefore, appears to consist, in part at least, of glycosides of the two acids named.

Substitutes.—Tampico jalap is the root of *Ipomœa simulans* Hanbury; it may be distinguished by its irregular shape, convoluted surface and absence of lenticels. It yields about 10 per cent. of resin (tampicin), which is entirely soluble in ether and may be identical with the ether-soluble resin of jalap and ipomœa. Brazilian jalap is the root of *Piptostegia Pisonis* Mart. (Fam. Convolvulacæ). It occurs in circular, transverse slices, about 3 to 5 centimetres in diameter and 1 centimetre thick, exhibiting several concentric rings and pale resin cells; it is pale greyish-brown in colour, and contains about 17 per cent. of resin, of which about 5 per cent. is soluble in ether.

Standard, B.P.—Jalap contains not more than 2 per cent. of foreign organic matter, and not less than 9 per cent. of resin.

Jalap, in powder, contains the constituents and possesses the diagnostic microscopical characters of Jalap, and complies with the limit for resin of the unground drug. When powdered jalap is prescribed, the standardised powder, Jalapa Pulverata, must be used.

Action and Uses.—Jalap is a powerful purgative, producing copious, watery evacuations. In large doses it causes considerable pain, and its preparations should not be used by those suffering from gastric or intestinal inflammation. Jalap appears to act only in the presence of bile, and the addition of soap increases its purgative power. Its action on the small intestine is very rapid, hence the liquid nature of the stools. Powdered jalap is too bulky for use in pills; for this purpose the resin is preferred. When jalap is prescribed, the standardised powder, Jalapa Pulverata, should be dispensed; it is generally administered as Pulvis Jalapæ Compositus. This preparation is a hydragogue cathartic employed in dropsy and chronic Bright's disease. A tincture and a compound tincture are also employed, the latter especially for use in India and the Colonies. Mixtures containing either of these tinctures require the addition of one-eighth of their volume of mucilage of acacia or mucilage of tragacanth in order to suspend the resin.

Preparations

Jalapæ Pulverata, B.P.—(Jalap. Pulverat.)—Powdered Jalap. *Syn.*—Pulvis Jalapæ. Jalap. reduced to a fine powder and adjusted with powdered exhausted jalap or lactose to contain 10 per cent. of resin (limits, 9 to 11). Ash, not more than 6·5 per cent. It should be stored in well-closed containers. Dose.—0·3 to 1·2 grammes (5 to 20 grains).

Pulvis Jalapæ Compositus, B.P.—(Pulv. Jalap. Co.)—Compound Powder of Jalap. Powdered jalap, 30 per cent., with potassium acid tartrate and ginger. Dose.—0·6 to 4 grammes (10 to 60 grains).

Tinctura Jalapæ, B.P.C.—(Tinct. Jalap.)—Tincture of Jalap. It contains from 1·45 per cent. to 1·55 per cent. w/v of resin. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopœia, 1914

Tinctura Jalapæ Composita, B.P.C.—(Tinct. Jalap. Co.)—Compound Tincture of Jalap. Jalap, 1 in 12 $\frac{1}{2}$, with scammony resin and turpeth. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopœia, 1914

JALAPÆ RESINA

(Jalap. Res.)

Jalap Resin

Jalap resin is a mixture of resins obtained from jalap by extraction with boiling alcohol, evaporating the alcohol, washing the residue with water, and drying. It occurs in the form of brownish, translucent, brittle fragments, breaking with a resinous fracture, or as a pale brown powder.

Insoluble in water; soluble in alcohol.

Standard.—Jalap resin contains not less than 85 per cent. of ether-insoluble resins, calculated on the substance dried at 100°. Loss on drying at 100°, not more than 5 per cent. Ash, not more than 0·5 per cent. Shake 1 gramme, in fine powder, with 20 millilitres of cold water, filter, and wash the residue with 5 millilitres of cold water; the residue on evaporation of the filtrate and washings, after drying at 100°, weighs not more than 0·02 gramme.

Assay.—Shake vigorously for fifteen minutes 1 gramme, in fine powder, with 50 millilitres of freshly distilled ether (0·720), and allow to stand over-night; pour off the ether, wash the residue with 10 millilitres of the ether, dry at 100°, and weigh the residue of ether-insoluble resins

Action and Uses.—Jalap resin has the properties of jalap. It causes evacuation more rapidly than the anthracene purgatives; the stools are watery and profuse, and evacuation may be accompanied by considerable pain and tenesmus. Jalap resin is **administered** in pills, which are best massed with syrup of liquid glucose; soap is often added to facilitate disintegration of the pill and to enhance

the action of the drug, and oleoresin of ginger may be added for its carminative effect.

Dose.—0·06 to 0·3 gramme (1 to 5 grains)

Preparation

Pilule Scammonie Compositæ, B.P.C.—(Pil. Scammon. Co.)—Compound Scammony Pills. Each pill contains 1 grain each of scammony resin, jalap resin and curd soap, and $\frac{1}{4}$ grain of ginger. **Dose.**—1 or 2 pills.

JALAPINUM

(Jalapin.)

Jalapin

Jalapin is the ether-insoluble portion of the resin obtained from jalap and may be prepared by precipitating an alcoholic solution of the purified resin with ether. It occurs as a white, odourless powder, and has an acrid and nauseating taste in alcoholic solution. The alcoholic solution is neutral, and reduces ammoniacal silver nitrate solution on gentle heating. It also reduces Fehling's solution, after first heating with dilute mineral acid. Melting-point, about 155°. It dissolves in alkalis with decomposition. Sulphuric acid produces a red colouration. Oxidation with nitric acid converts it into oxalic and sebacic acids. The ether-insoluble portions of the resins obtained from scammony root and ipomœa are said to be identical with jalapin. The name jalapin is also applied in Germany to the ether-soluble resin of ipomœa.

Soluble in alcohol, glacial acetic acid and ethyl acetate; slightly soluble in chloroform; insoluble in ether, light petroleum, benzene and water.

Action and Uses.—Jalapin possesses properties similar to those of jalap resin, but is considered to be less active. It may be **administered** in cachets, or in pills prepared with syrup of liquid glucose and containing, preferably, soap and oleoresin of ginger or capsicum. It is sometimes prescribed with calomel as a brisk purge and as an anthelmintic.

Dose.—0·06 to 0·3 gramme (1 to 5 grains).

JUNIPERUS

(Junip.)

Juniper

Synonyms—Juniperi Fructus; Juniper Berry

Juniper consists of the ripe fruits of *Juniperus communis* Linn. (Fam. Pinacæ), an evergreen shrub or small tree growing chiefly on chalky downs in temperate Europe, Asia and North America.

The fruit is a subspherical galbulus, from about 0.5 to 1 centimetre in diameter, deep purplish-black, sometimes with a reddish tint, and covered with a greyish, waxy bloom. At the apex is a three-rayed furrow where the three fleshy scales meet, and at the tip of each scale is a brown, corky projection. At the base are one or more whorls each of three small bracts, the whorls alternating with one another. Internally, embedded in the fleshy scales, are three ovate seeds, each with a hard woody testa, to which a few large, ovoid oil-glands are attached. The odour is aromatic and the taste sweet, terebinthinate and bitterish.

Juniper **contains** volatile oil (about 0.5 to 2 per cent.), resin (about 10 per cent.), fermentable sugar (about 33 per cent.), a bitter substance, juniperin, and organic acids.

Action and Uses.—The action of juniper resembles that of oil of juniper. The drug is used as a constituent of compound powders, especially in veterinary practice.

KALADANA

(Kalad.)

Kaladana

Synonym—Pharbitis Seeds.

Kaladana consists of the dried seeds of *Ipomœa hederacea* Jacq. (Fam. Convolvulaceæ), a twining plant indigenous to India.

The seeds are about 5.5 millimetres long and about 3.7 millimetres wide, 100 weighing from 3 to 4 grammes. In shape they vary from approximately a sixth to a quarter segment of an oblate spheroid. On the curved surface is a central, shallow, longitudinal groove. The two flat faces, which are about as wide as the curved surface, meet at an angle, usually between 60 and 85 degrees, forming a ridge, near the proximal end of which is a cordate, hilar depression, brownish in colour, due to a dense covering of short, brown hairs which do not project above the level of the general surface. The testa is dull black, hard, smooth and apparently glabrous; on magnification, short trichomes become visible as white dashes. The taste is at first sweetish but subsequently acrid. A longitudinal section shows two plaited cotyledons in which numerous resin cells are visible, a narrow, mucilaginous endosperm which lines the testa and penetrates between the larger folds of the cotyledons, and a crescent-shaped hypocotyl-radicle, the radicle end of which is bluntly pointed.

The diagnostic **microscopical** characters are the tangentially elongated, wavy-walled cells of the epidermis, upon which are sparsely scattered trichomes varying in length from 60 to 200 microns and the pitted cells of the nutritive layer.

Kaladana **contains** about 12 per cent. of fixed oil and 16 per cent. of a resinous substance consisting of a true resin associated with glycosidal

matter and probably a small amount of a saponin. The true resin, which amounts to about 2 per cent. of the drug, is not glycosidal and is not identical with the ether-insoluble resin of jalap.

Substitutes.—Seeds of other species of *Ipomæa* frequently occur in the commercial drug. The most important of these is the seed of *Ipomæa muricata* Jacq. which is brown and glabrous. The seeds are about 8.5 millimetres long and about 6 millimetres wide, and there is no longitudinal groove on the arched dorsal surface; 100 weigh from 14 to 18 grammes. Seeds of *Crotalaria juncea* Linn. and of *Acacia arabica* Willd. occur as admixtures, and the seeds of *Peganum Harmala* Linn. and of *Ocimum Basilicum* Linn. are sometimes sold in India as kaladana.

Action and Uses.—Kaladana is used as an equivalent of jalap in India and the Eastern Colonies. A compound powder (*Pulvis Kaladanæ Compositus*) and a tincture (*Tinctura Kaladanæ*) are prepared, and are of the same strength as, and used in a similar manner to, the corresponding preparations of jalap.

Dose.—2 to 3 grammes (30 to 45 grains).

KALADANÆ RESINA.—Kaladana resin is used in India and the Eastern Colonies as a substitute for jalap resin, which it closely resembles in its action.
Dose.—0.12 to 0.5 gramme (2 to 8 grains).

KAMALA

(Kamal.)

Kamala

Synonym—*Glandulæ Rottleræ*.

Kamala consists of the hairs and glands separated from the fruits of *Mallotus philippinensis* Müll. Arg. (Fam. Euphorbiaceæ), a small tree widely distributed throughout India and the Malay Archipelago. The drug is obtained by rubbing the small three-celled fruits and sifting the resulting powder.

The drug forms a fine, mobile, dull reddish-brown powder of heterogeneous nature, which floats when sprinkled on water, the liquid remaining colourless. With chloroform, ether and solutions of caustic alkalis, a reddish-brown solution is obtained. It is odourless and tasteless. Examined **microscopically**, the glands are sub-globular, from 40 to 100 microns in diameter, and contain numerous club-shaped cells, radiately arranged, and embedded in a dark red, resinous mass, which is surrounded by a delicate cuticle. The hairs are thick-walled, unicellular, pointed, curved, and arranged in radiating groups of two to ten. A small amount of vegetable debris is unavoidably associated with the hairs and glands.

Kamala **contains** rottlerin, a substance which crystallises in thin, salmon-coloured plates; the drug also contains yellow and red resins, wax and a yellow, crystalline substance. So-called *isorottlerin* appears to be impure rottlerin.

Substitutes and Adulterants.—Waras, Wurus, or True Wars, consists of the hairs and glands of the fruits of *Flemingia congesta* Roxb (Fam. Leguminosæ). It is distinguished by the dull purplish colour, the cylindrical shape of the glands, the constituent cells, which are arranged in tiers, and the hairs, which occur singly. Ground safflower and dried starch, if present, are readily distinguished microscopically. The presence of ferric oxide and ferruginous sand is detected by mixing with water when such particles sink; the ash is also considerably increased.

Standard.—Kamala yields not more than 9 per cent. of ash.

Action and Uses.—Kamala is employed as an anthelmintic against tape-worm. It produces free purgation and is usually very efficacious, expelling the worm. The powder may be given mixed with honey, gruel or treacle, or made into a draught with mucilage of acacia and water. The dose should be preceded by doses of sodium bicarbonate three times a day for forty-eight hours. No purge need be given after the powder.

Dose.—2 to 8 grammes ($\frac{1}{2}$ to 2 drachms).

KAOLINUM

(Kaolin.)

Kaolin

Synonym—China Clay.

Kaolin is a native aluminium silicate, powdered and freed from gritty particles by elutriation. The native clay is derived from the decomposition of the felspar of granite rocks and contains approximately 47 per cent. of silica, 40 per cent. of alumina and 13 per cent. of water. It is found in large quantities in Cornwall. Varieties of kaolin consisting of finely divided particles are sometimes described as colloidal kaolin; they are produced by various processes, some of which involve electrical precipitation. Kaolin occurs as a soft, whitish powder, odourless when dry, but developing a clay-like odour when moistened. It has an earthy taste, is insoluble in all ordinary solvents and is unaffected by most chemical reagents. When fused with alkalis, silicates and aluminates of the alkali metals are formed. An impure variety of kaolin, containing iron and magnesium, is known as "fuller's earth"; a purer form is known as "white fuller's earth."

Insoluble in water and mineral acids.

Standard, B.P.—Kaolin loses, on ignition at a red heat, not more than 15 per cent. of its weight. Arsenic limit, 2 parts per million. Lead limit, 5 parts per million. It complies also with limit tests for matter soluble in N/5 hydrochloric acid, and for chloride.

Action and Uses.—Kaolin has the property of adsorbing toxins from the alimentary canal, and its use for this purpose is indicated in the treatment of cholera, dysentery, colitis and similar infections. It is

usually **administered** as a suspension in water or liquid paraffin. It is sometimes used in place of bismuth carbonate to form a protective coating to the gastro-intestinal mucous membrane. Kaolin is employed for its absorbent properties in the preparation of pill masses, especially in the presence of substances, such as phosphorus, which are readily oxidised. In the form of Unguentum Kaolini, it is used to prepare pills of potassium permanganate, silver nitrate, and other substances which would be reduced by contact with the organic matter of ordinary pill excipients. Kaolin is used in place of fuller's earth in dusting and toilet powders; it is absorbent, and prevents irritation due to friction. It is also used in the preparation of Cataplasma Kaolini, which has largely replaced the domestic linseed and bread poultices. Kaolin is also used as a filtering medium to clarify syrups and cloudy solutions of volatile oils, and forms a silicate basis for many carbolic and similar disinfectant powders.

Dose.— 15 to 60 grammes ($\frac{1}{2}$ to 2 ounces).

Preparations

Cataplasma Kaolini, B.P.—(Cataplasma Kaolin.)—Poultice of Kaolin. It contains approximately 53 per cent. w/w of kaolin, with boric acid, methyl salicylate, oil of peppermint, thymol and glycerin.

This poultice was included in the British Pharmaceutical Codex, 1923.

Emulsio Paraffini Liquidi et Kaolini, B.P.C.—(Emuls. Paraff. Liq. et Kaolin.)—Emulsion of Liquid Paraffin and Kaolin. Each fluid ounce contains 2 fluid drachms of liquid paraffin and about 80 grains of kaolin. Dose.— 15 to 60 millilitres ($\frac{1}{2}$ to 2 fluid ounces).

Unguentum Kaolini, B.P.C.—(Ung. Kaolin.)—Kaolin Ointment. *Syn.*—Massa Kaolini; Kaolin Mass. Kaolin, 1 in 4, with hard and soft paraffins.

KAVA

(Kava)

Kava

Synonyms—Kavæ rhizoma; Kava-Kava.

Kava is the rhizome of *Piper methysticum* Forst. (Fam. Piperaceæ), a shrub indigenous to the Sandwich Islands. The roots and periderm are removed from the rhizome, which is cut into irregular pieces, and dried.

The rhizome occurs in irregularly cubical or wedge-shaped pieces from 1.5 to 5 centimetres in thickness, pale greyish-white to greyish-brown in colour and of a somewhat loose texture. The transversely cut surface is whitish and mealy, and shows a large, shrunken pith surrounded by narrow, radial strands of xylem, separated by paler and wider medullary rays and extending almost to the outer surface. The fracture is coarsely fibrous and starchy. The odour is slight and agreeable, and the taste is at first bitter and subsequently numbing.

In addition to resin and much starch, kava **contains** methysticin, kawain and yangonin. The substance known as pseudomethysticin is a mixture of methysticin and dihydromethysticin. The drug also contains dihydroyangonin and kawaic acid.

Substitutes.—The unpeeled drug, covered with a dark grey cork, is frequently found in commerce. Smaller pieces, with numerous stout roots attached, are frequently present.

Action and Uses.—Kava resembles pepper in its local action and is employed medicinally as an antiseptic and diuretic in inflammatory conditions of the genito-urinary tract. It is **administered** in the form of liquid extract.

Preparation

Extractum Kavæ Liquidum, B.P.C.—(Ext. Kavæ Liq.)—Liquid Extract of Kava. 1 in 1. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This liquid extract was included in the British Pharmacopœia, 1914

KERATINUM

(Keratin.)

Keratin

Keratin is a name applied to a group of proteins which form the chief constituents of horns, hoofs, feathers, hair, wool, etc., and which have in common the property of being very resistant to enzyme action and chemical reagents. They are characterised by a high proportion of sulphur in their composition, due to the large amount of cystine present. Keratins are insoluble in water and dilute acids or alkalis. They are slowly hydrolysed by boiling concentrated acids, and fairly readily hydrolysed by strong alkalis in the cold. Keratins are remarkable for the rapidity with which they are attacked by the sulphides of the alkali metals and the alkaline earth. They are not attacked by pepsin, trypsin, or bacterial tryptases. Keratin may be obtained by macerating horn shavings or goose quills for several days in a mixture of equal parts of ether and alcohol, decanting the liquid and washing the residue with warm water. The washed shavings are then treated for several hours with an acidified solution of pepsin at 40°. After further washing with distilled water, the residue is dried and powdered. It may be further purified by boiling with glacial acetic acid for about thirty hours in a flask with a reflux condenser, filtering the solution thus obtained through glass-wool and evaporating it to a thick syrupy consistence, after which it may be spread on glass plates, dried between 60° and 70°, and scaled.

Keratin occurs as a brownish-yellow powder, or in transparent, white or greyish-white scales, without taste or odour. It may be softened by prolonged boiling in water, and is decomposed by boiling under pressure, a turbid solution being formed and hydrogen sulphide liberated. On

ignition, it leaves about 1 per cent. of ash. After digesting for twenty-four hours with fifteen times its weight of dilute solution of ammonia or glacial acetic acid, at about 40°, keratin leaves about 3 per cent. of insoluble residue.

Insoluble in water, alcohol and ether.

Action and Uses.—Keratin is used in pharmacy mainly for the purpose of coating pills, tablets and capsules that are required to pass through the stomach unchanged, in order that the contents may exert their action only in the intestines, but its efficiency for this purpose is doubtful.

Preparation

Liquor Keratini, B.P.C.—(Liq. Keratin.)—Solution of Keratin. Keratin, about 10 per cent. w/v, with strong solution of ammonia and alcohol (90 per cent.).

KINO

(Kino)

Kino

Synonyms—East Indian, Malabar, Madras, or Cochin Kino.

Kino consists of the dried juice obtained from the trunk of *Pterocarpus Marsupium* Roxb. (Fam. Leguminosæ), a tree growing in Southern India and Ceylon. The juice is contained in longitudinal rows of superposed cells, 50 to 100 microns wide, in the phloem. Vertical incisions, with oblique lateral ones running into them, are made in the bark of the tree; the thick, reddish juice that exudes is collected and dried, and yields about half its weight of kino, which readily breaks into small fragments. The juice should be boiled before drying so as to destroy the enzymes and prevent them from bringing about changes which readily occur in the unboiled juice on exposure to air.

Kino occurs in small (about 3 to 5 millimetres), angular, glistening, brittle fragments which appear to be almost black in colour, but the edges when viewed by transmitted light, are seen to be ruby-red and transparent. The fragments break with a glassy fracture and yield a brownish-red powder, but the drug is, however, very free from dust. It is odourless and has a sweetish and astringent taste; on being chewed it adheres to the teeth and colours the saliva red. Kino is partly **soluble** (about 60 to 70 per cent.) in cold water, but more soluble (about 90 per cent.) in boiling water; the solution is slightly acid and gives a dark green precipitate with ferric chloride solution and a reddish-violet colour with solutions of alkalis. It yields to alcohol (90 per cent.) about 75 per cent. of extractive. On the addition of 2 millilitres of N/10 iodine to 5 millilitres of a filtered 1 per cent. solution of kino in cold water, a slight precipitate is produced which dissolves on adding 0.5 millilitre of dilute ammonia solution (distinction from butea kino); if the liquid is

boiled for one minute and cooled before adding the dilute ammonia solution, the precipitate is insoluble (distinction from eucalyptus kino).

Kino **contains** kinotannic acid (70 to 80 per cent.). It also contains kino red, a phlobaphene produced from kinotannic acid by oxidation, and small quantities of pyrocatechin (catechol), protocatechuic acid, gallic acid, and gum. The presence of an oxydase causes oxidation of the kinotannic acid to proceed slowly in the drug, which gradually becomes duller in appearance; oxidation also takes place in aqueous and alcoholic solution, the phlobaphene produced causing the liquid to gelatinise. Since the activity of the enzyme is destroyed by heat, a tincture of kino which has been boiled will not undergo gelatinisation. The proportion of kinotannic acid present in the drug has been variously stated, but appears, in good fresh samples assayed by the hide powder process, to range from 70 to 82 per cent. Kino contains about 15 per cent. of moisture.

Substitutes.—African kino, from *Pterocarpus erinaceus* Lam., eucalyptus kino, from *Eucalyptus rostrata* Schlecht. and other species of *Eucalyptus*, and butea kino, from *Butea frondosa* Roxb., occur in commerce.

Standard.—Kino yields to boiling water, not less than 75 per cent. of extractive. Ash, not more than 2·5 per cent.

Kino, in powder (Pulvis Kino: Pulv. Kino), contains the constituents of, and complies with the standard for, the unground drug.

Action and Uses.—Kino is a powerful astringent used either externally or internally. It has the general properties of substances containing a large proportion of tannic acid (see Acidum Tannicum), and has the advantage over the pure substance of not being so readily absorbed, and of exerting its astringent action in the intestine without upsetting the stomach, since the tannin is liberated only slowly in the alimentary canal. For inflamed throat, kino lozenges are employed. The tincture is added to gargles (1 to 16), and, mixed with tincture of myrrh and diluted with water, it is used as an astringent wash for spongy gums. Internally, kino is **administered** as Pulvis Kino Compositus in obstinate diarrhœa and dysentery, the powder being given enclosed in a cachet or a glutoid capsule. The tincture may be prescribed with bismuth salts or chalk mixture in the treatment of diarrhœa.

Dose.—0·3 to 1·2 grammes (5 to 20 grains).

Preparations

Pulvis Kino Compositus, B.P.C.—(Pulv. Kino. Co.)—Compound Powder of Kino. Kino, 75 per cent., powdered opium, 5 per cent., and cinnamon, 20 per cent. Dose.—0·3 to 1·2 grammes (5 to 20 grains).

This powder was included in the British Pharmacopœia, 1914.

Tinctura Kino, B.P.C.—(Tinct. Kino)—Tincture of Kino. 1 in 10. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopœia, 1914.

KINO EUCALYPTI

(Kino Eucalyp.

Eucalyptus Kino*Synonyms*—Gummi Eucalypti; Red Gum.

Eucalyptus kino consists of the dried juice obtained from *Eucalyptus rostrata* Schlecht., and other species of *Eucalyptus* such as *E. marginata* Smith and *E. amygdalina* Labill. (Fam. Myrtaceæ), indigenous to New South Wales, Australia, and found especially along the banks of the Murray River. The secretion-cavities occurring in the wood, or sometimes in the cambial zone, are tapped by making incisions, under each of which a V-shaped strip of metal is fixed, by which means the exuding liquid is drained into containers; the viscous fluid is evaporated by boiling, and on drying it becomes solid and friable.

Eucalyptus kino occurs in irregular fragments (about 5 to 10 millimetres) of a dark reddish-brown colour, opaque and more or less dusty; thin flakes are somewhat transparent and ruby-red by transmitted light; it yields a reddish-brown powder having an astringent taste, and adhering to the teeth, colouring the saliva red. The solution in water is neutral to litmus. On the addition of 2 millilitres of N/10 iodine to 5 millilitres of a filtered 1 per cent. solution of eucalyptus kino in cold water, a precipitate is produced which dissolves on adding 0.5 millilitre of dilute ammonia solution (distinction from *butea kino*); if the liquid is boiled for one minute and cooled before adding the dilute ammonia solution, the precipitate is soluble (distinction from kino).

The composition of eucalyptus kino appears to vary considerably, according to the species from which it is obtained. It contains kinotannic acid which gives a green colouration with ferric chloride. Other constituents which may be present are a tannin glycoside, an insoluble phlobaphene (kino red), catechin, pyrocatechin (catechol), resin, and crystallisable bodies named eudesmin and aromadendrin. *Eucalyptus kino* contains about 15 per cent. of moisture. It yields to alcohol (90 per cent.) about 90 per cent. of extractive, and to cold water about 80 per cent. of extractive.

Standard.—*Eucalyptus kino* yields to alcohol (90 per cent.) not less than 80 per cent. of extractive. Ash, not more than 3 per cent.

Eucalyptus kino, in powder (*Pulvis Kino Eucalypti*: *Pulv. Kino Eucalyp.*), contains the constituents of, and complies with the standard for, the unground drug.

Action and Uses.—*Eucalyptus kino* is a valuable astringent for the throat. Its action is similar to that of kino, but weaker and more prolonged. It is administered in the form of lozenges and pastilles. *Extractum Kino Eucalypti Liquidum* is a styptic; diluted with 15 parts of water, it is used as an astringent gargle. The tincture is used similarly. The powdered drug, the tincture, and the liquid extract are

used internally as astringents in the treatment of diarrhoea and dysentery.

Dose.—0·3 to 1·2 grammes (5 to 20 grains).

Preparations

Extractum Kino Eucalypti Liquidum, B.P.C.—(Ext. Kino Eucalyp. Liq.)—Liquid Extract of Eucalyptus Kino. *Syn.*—Extractum Gummi Rubri Liquidum; Liquid Extract of Red Gum. 1 in 4. *Dose.*—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tinctura Kino Eucalypti, B.P.C.—(Tinct. Kino Eucalyp.)—Tincture of Eucalyptus Kino. *Syn.*—Tinctura Gummi Rubri; Tincture of Red Gum. 1 in 4. *Dose.*—1 to 2·6 millilitres (15 to 40 minims).

Trochisci Kino Eucalypti, B.P.C.—(Troch. Kino Eucalyp.)—Eucalyptus Kino Lozenges. *Syn.*—Red Gum Lozenges; Eucalyptus Gum Lozenges. Each lozenge contains 1 grain of eucalyptus kino.

This lozenge, containing 0·06 gramme of eucalyptus kino, was included in the British Pharmacopœia, 1914.

KOLA

(Kola)

Kola

Synonyms.—Kola Nuts; Cola Seeds.

Kola consists of the dried cotyledons of *Cola vera* K. Schum. (Fam. Sterculiaceæ), a large tree growing wild in Sierra Leone, North Ashanti, and near the sources of the Niger, and cultivated in West Africa, the West Indies, Brazil and Java.

The cotyledons vary from 2 to 5 centimetres in length and are rather less in breadth. The shape is roughly plano-convex but varies considerably. Externally, the cotyledons are reddish-brown in colour, hard and solid, and break with a uniform fracture, the fractured surface being somewhat lighter in colour. There is no marked odour, but the taste is slightly bitter and astringent.

Kola **contains** caffeine (about 1·5 per cent.), traces of theobromine, kola red, fat, an oxydase, sugar and starch. The ash averages about 2 per cent.

Substitutes.—The seeds of *Cola acuminata* Schott and Endl., a tree growing in the Cameroons, having 3 to 5 cotyledons, are sometimes on the market; they contain less caffeine. Seeds with 6 cotyledons are also met with, these are derived from *Cola Ballayi* Cornu, and contain but little caffeine.

Action and Uses.—The properties of kola are virtually those of caffeine, modified slightly by the astringent matter present. The powdered drug is prepared in the form of chocolate and cocoa for its stimulating and sustaining properties. The liquid extract is sometimes used with liquid extract of coca, as a stimulant, or with phenazone, for use in migraine, mucilage being added to suspend resinous matters.

Dose.—1 to 3 grammes (15 to 45 grains).

Preparations

Extractum Kolæ Liquidum, B.P.C.—(Ext. Kolæ Liq.)—Liquid Extract of Kola. 1 in 1. Dose.—0·6 to 1·2 millilitres (10 to 20 minims).

Tinctura Kolæ, B.P.C.—(Tinct. Kolæ)—Tincture of Kola. 1 in 5. Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

KRAMERIA

(Kramer.)

Krameria

Synonyms—Krameria Radix; Krameria Root; Rhatany Root.

Krameria consists of the dried root of *Krameria triandra* Ruiz et Pav. (Fam. Leguminosæ), a shrubby plant indigenous to the mountain slopes of Peru and Bolivia. It is known in commerce as Peruvian rhatany.

The drug consists of a knotty crown, about 3 to 5 centimetres wide, to which are attached a number of nearly straight, but somewhat tortuous, roots which are dark reddish-brown and have a scurfy or, in the older pieces, a rugged and scaly bark; the smaller and smoother pieces show no conspicuous transverse fissures; the fracture is fibrous in the bark and splintery in the wood. The smoothed, transversely cut surface shows a dark reddish-brown bark, extending up to about one-third of the radius in thickness, and a dense, pale reddish-brown and finely porous wood which is traversed by numerous fine medullary rays and often shows a central, darker heartwood. The drug is odourless, but the bark has an astringent taste; the wood is almost tasteless.

The diagnostic **microscopical** characters are the thin-walled cork cells containing a dark reddish-brown colouring matter; the small groups of long, unligified, phloem fibres, accompanied by files of parenchyma containing prisms or sandy crystals of calcium oxalate; the numerous simple and compound starch grains, up to 40 microns in diameter, from the general parenchyma; the large amount of strongly thickened fibres and the vessels from the xylem.

Krameria **contains** about 8·5 per cent. of krameriatannic acid. The root also contains a dark red phlobaphene (krameria red), produced by the decomposition of the tannin, together with starch, etc. It yields to alcohol (60 per cent.), from 30 to 40 per cent. of extractive.

Substitute.—The root of *K. argentea* Mart. is exported from Brazil and is known in commerce as Pará rhatany. It may be distinguished by the appearance of the outer surface, which is of a deep purplish-brown colour, longitudinally wrinkled, and bears deep transverse fissures at intervals of about 6 to 12 millimetres, but is not rough or scaly. It is rarely over 12 millimetres in thickness and the width of the bark, as seen in section, is equal to about half the radius. The alcohol-soluble extractive is less than that of krameria and the tincture gives a clear solution when diluted with water.

Standard, B.P.—Krameria contains not more than 2 per cent. of foreign organic matter. Ash, not more than 6 per cent.

Krameria, in powder (Pulvis Krameriaë · Pulv. Kramer.), contains

the constituents and possesses the diagnostic microscopical characters of *Krameria*, and complies with the limit for ash of the unground drug.

Action and Uses.—*Krameria* is a powerful astringent, used both externally and internally, and has the general properties of tannic acid. It is used with or without cocaine, in the form of a lozenge or pastille, for sore throats. *Extractum Krameriaë Siccum* is given in pills as an intestinal astringent; it may also be used in the form of a suppository, with opium if necessary, for bleeding or prolapsed hæmorrhoids. The powdered root is added to tooth powders for use when the gums are spongy and inflamed. *Tinctura Krameriaë*, diluted with 12 parts of water, is used as a gargle for inflamed throats, and as a mouth-wash in stomatitis. Preparations of *krameria* are **incompatible** with gelatin and salts of iron.

Dose.—0·6 to 2 grammes (10 to 30 grains).

Preparations

Extractum Krameriaë Siccum, B.P.—(*Ext. Kramer. Sicc.*)—Dry Extract of *Krameria*. It is prepared with water and evaporated to dryness under reduced pressure. It should be stored in small, wide-mouthed well-closed containers in a cool place. **Dose.**—0·3 to 1 gramme (5 to 15 grains).

Infusum Krameriaë Concentratum, B.P.C.—(*Inf. Kramer. Conc.*)—Concentrated Infusion of *Krameria*. 1 in 2½. This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh infusion of *krameria* and differs also in containing a small proportion of alcohol. **Dose.**—2 to 4 millilitres (½ to 1 fluid drachm).

Infusum Krameriaë Recens, B.P.C.—(*Inf. Kramer. Rec.*)—Fresh Infusion of *Krameria*. *Syn.*—Infusion of Rhatany. 1 in 20. When infusion of *krameria* or *Infusum Krameriaë* is prescribed, fresh infusion not being specified, either *Infusum Krameriaë Recens*, or *Infusum Krameriaë Concentratum* suitably diluted, may be dispensed.

This infusion was included in the British Pharmacopœia, 1914, under the name of Infusum Krameriaë.

Tinctura Krameriaë, B.P.—(*Tinct. Kramer.*)—Tincture of *Krameria*. 1 in 5, by percolation with alcohol (60 per cent.). **Dose.**—2 to 4 millilitres (½ to 1 fluid drachm).

Trochiscus Krameriaë, B.P.—(*Troch. Kramer.*)—Lozenge of *Krameria*. *Syn.*—*Krameria* Lozenge. Each lozenge contains approximately 0·06 gramme or 1 grain of dry extract of *krameria*.

Trochiscus Krameriaë et Cocainæ, B.P.—(*Troch. Kramer. et Cocain.*)—Lozenge of *Krameria* and Cocaine. *Syn.*—*Krameria* and Cocaine Lozenge. Each lozenge contains approximately 0·06 gramme or 1 grain of dry extract of *krameria* and approximately 0·003 gramme or ½ grain of cocaine hydrochloride.

LAC COACTUM

(*Lac Coact.*)

Curdled Milk

Synonym.—Soured Milk.

Curdled milk is prepared by sterilising cows' milk by heating it in

an autoclave at a temperature of 125° for thirty minutes and cooling to 40°; a culture of *Bacillus bulgaricus* or *B. acidophilus* is then added and the temperature maintained at 38° to 40° for eight to twelve hours, according to the concentration and activity of the culture employed. The organisms may be added as liquid cultures or in lightly compressed tablets. They should be freshly prepared. The tablets contain the bacilli in a more or less dormant condition, and require a longer incubation with milk to produce curdled milk.

Action and Uses.—Curdled milk is employed as an intestinal antiseptic to inhibit the growth of putrefactive micro-organisms. Its action is due to the massive ingestion of the lactic acid-producing bacilli, many of which pass through the stomach into the intestinal tract where they produce a pH unsuited to the growth of many forms of putrefactive bacteria. The flora of the tract is changed and the reaction altered to suit the growth of the benign micro-organisms.

LACTIC ACID MILK consists of cows milk to which has been added one drachm of lactic acid, drop by drop, to each pint. It should be freshly prepared (see *Acidum Lacticum*). Dried lactic acid milks, which when reconstituted by the addition of water represent whole milk, half-cream milk, and separated milk, are in common use. Lactic acid milk is used in infant feeding and in cases of gastro-enteritis associated with diminished secretion.

HYDROCHLORIC ACID MILK is made by adding 40 minims of dilute hydrochloric acid to a pint of fresh milk. It is used in cases of lactalbumin sensitiveness, especially associated with a deficiency of gastric secretion. It finds its greatest use in cases of eczema and asthma in childhood.

LACCA

(Lac.)

Shellac

Shellac consists of a resinous substance prepared from a secretion that encrusts the bodies of a scale insect, *Tachardia lacca* R. Blanchard (Order Hemiptera, Fam. Coccideæ), which lives on the juices of the stems of various plants; the best known of these are *Butea frondosa* Roxb., *Ficus religiosa* Linn., *Schleichera trijuga* Willd., *Shorea robusta* Gaertn. and *Zizyphus jujuba* Lam., but there are also plants specially grown for the purpose, including *Acacia arabica* Willd. and *Cajanus indicus* Spreng. Most of the shellac of commerce comes from Mirzapore and Calcutta. The encrusted twigs, collected from the trees during May, June, October and November, are known as "stick lac." The resinous crust is broken from the twigs, washed with water to remove the red colouring matter, known as "lac dye," and dried, thus forming "seed lac." The washed and dried seed lac is melted with a certain proportion of orpiment and resin in bags of special cloth.

through which it is pressed. This molten lac is placed on a surface heated by means of hot water, and spread into a sheet or skin about 3 millimetres in thickness. This is further stretched out, and so made to yield a very thin, paper-like, sheet shellac. It is then sorted according to colour.

Shellac occurs in thin fragments or scales, varying in size, and often somewhat curved, reddish-orange to reddish-brown in colour, transparent, hard and brittle, odourless and tasteless. The palest variety is the most esteemed, and is known as "orange" shellac. The darker varieties, known as "ruby," "garnet," etc., diminish in value in proportion to the depth of colour. Shellac is insoluble in water, but easily soluble in alcohol, especially on heating; it is soluble also in solutions of potassium and sodium hydroxides, and borax. Cold light petroleum, free from water and alcohol, extracts only about 5 per cent., consisting chiefly of wax. Digested with ammonia in a closed vessel, shellac swells to a gelatinous mass. The iodine value at 22° is between 10 and 20.

Shellac **contains** about 6 per cent. of wax, about 6·5 per cent. of a pigment named laccin or laccaic acid, 70 to 85 per cent. of resinous matter, 65 per cent. of which is insoluble in ether and 35 per cent. soluble in ether containing alcohol. The part insoluble in ether is probably a resinotannol ester of aleuritic acid, while the ether-soluble portion includes a yellow colouring matter called erythrolaccin.

Varieties.—"Button lac" and "garnet lac" are made from "seed lac," which is melted and then cooled by throwing it on to water.

Substitutes.—Colophony is added to lower the melting-point, an essential condition for many industries, and it is frequently present to the extent of from 2 to 5 per cent., few shellacs being entirely free from it. Colophony is detected by dissolving the sample in alcohol, pouring the solution into water, collecting and drying the precipitate, triturating it with light petroleum, filtering the liquid, and shaking the filtrate with a small quantity of water containing 0·1 per cent. of copper acetate; when colophony is present the light petroleum layer will show an emerald-green colour. The iodine value is also raised, colophony having a fairly constant iodine value of about 228 at 22°. "Bleached shellac" is prepared by treating an alkaline solution with chlorine or sulphurous acid, when, on the addition of sulphuric acid, it is obtained as a precipitate, which is collected, washed, "pulled" under water, and finally twisted into sticks and thrown into cold water. It has a yellowish-white colour and a silky lustre. It is readily soluble in alcohol or wood naphtha when freshly prepared, or when preserved under water, but becomes insoluble on exposure to the air or even on long keeping under water. "Liquid shellac" is formed by boiling shellac with solution of sodium hydroxide; on cooling, sulphuric acid is added, and the precipitated, viscous, liquid shellac can then be extracted with ether. It is a thick liquid, insoluble in water, but soluble in alcohol and ether. It forms salts with lead, zinc, barium and magnesium; the magnesium salt is amorphous, very soluble in water, precipitated on boiling, but redissolved on cooling.

Uses.—Shellac is of importance in the arts but is not used in medicine. It is the chief constituent of sealing wax, and is an ingredient of many varnishes and polishes. An ammoniacal solution is sometimes used as an enteric coating for pills and capsules.

LACTOSUM

(Lactos.)

Lactose*Synonyms*—Saccharum Lactis; Milk Sugar.

Lactose, or α -lactose, is a crystalline disaccharide which may be obtained from the whey of milk by gently evaporating to a low bulk and setting aside for a few days, when the sugar crystallises out as a yellow, granular mass, and is subsequently decolourised with charcoal and re-crystallised. Lactose occurs as an odourless, white, crystalline powder, with a slightly sweet taste. The aqueous solution is dextrorotatory and reduces Fehling's solution when heated. Dilute acids convert it into galactose and dextrose; heated with alkalis it becomes brown. When heated to 130° , it loses its water of crystallisation without melting and leaves a white, hygroscopic mass; at higher temperatures, it melts, swells up and burns, evolving an odour of burnt sugar and leaving a bulky, carbonaceous residue. β -Lactose is also obtainable; it is anhydrous, more soluble than lactose, and passes to the α form in solution.

Soluble in water (1 in 7), boiling water (1 in 1); almost insoluble in alcohol (90 per cent.), ether and chloroform

Standard, B.P.—Lactose has a specific rotation at 20° , determined on a 10 per cent. w/v boiled solution, of not less than $+52^\circ$ and not more than $+52.6^\circ$. Ash, not more than 0.1 per cent. Arsenic limit, 1 part per million. Lead limit, 2 parts per million. It complies also with limit tests for more soluble sugars, copper and acidity

Action and Uses.—Lactose is a valuable nutrient. It is less sweet than sucrose and is less liable to cause intestinal fermentation. It is largely employed in the humanisation of cows' milk for infants. Lactose for general use is the most satisfactory form of sugar for infant feeding, but should not be used in excessive quantities since it is too laxative and renders the stools too acid. Mixtures of carbohydrates obtained by the partial hydrolysis of starch are also used. Cows' milk contains about 4.5 per cent. of lactose, whilst normal human milk approximates to 6.5 per cent. When cows' milk is diluted with water to reduce the casein content, lactose is added to bring up the strength to 6.5 per cent. of the whole. Lactose may sometimes appear in the urine of infants having diarrhoea, since any lactose which enters the blood is immediately excreted, the renal threshold for this sugar being practically zero. Demonstrable quantities of lactose are excreted in the urine, during the first five days after parturition, by about 40 per cent. of women; the amount may be as much as 2 per cent.

Lactose is slightly laxative and diuretic. It has been used in doses of 8 to 16 grammes (2 to 4 drachms) daily as a diuretic in renal dropsy. Large doses of lactose are given with living cultures of *Bacillus acidophilus* when it is desired to favour the growth of this organism in the

intestine in the treatment of intestinal intoxication. It is employed in pharmacy as a diluent for standardised vegetable products and for powders. It is used as an absorbent in the preparation of some extracts, but though less prone to absorb moisture than sucrose, it is not so suitable for this purpose as an inert vegetable powder.

LACTUCA

(*Lactuc.*)

Lettuce

Synonym—Wild Lettuce.

Lettuce is the fresh, flowering herb, *Lactuca virosa* Linn. (Fam. Compositæ), a biennial plant indigenous to Europe and Northern Asia and cultivated in Britain and most European countries.

The plant has an erect, solid stem from 60 to 120 centimetres high, prickly near the base, smooth and branching above, and producing more or less leafy panicles of small, pale yellow flowerheads. The lower leaves are large, sessile, oblong-ovate, coarsely toothed and usually bear stiff bristles or prickles on the under surface of the midrib and lateral veins. The upper leaves are smaller, amplexicaul and more or less deeply lobed. The florets number six to twelve and are all ligulate; the fruit is small and flattened and bears a slender beak about as long as the fruit. From the leaves and stem when incised, there exudes a copious, white, bitter latex, having a characteristic odour somewhat similar to that of opium.

Lettuce **contains**, in addition to the constituents of the latex, traces of a mydriatic alkaloid.

Action and Uses.—Lettuce is a mild sedative and hypnotic, and is used in the treatment of irritable cough. Extractum Lactucae is prescribed in pill form, sometimes with calomel, and is an ingredient of lozenges and pastilles.

LACTUCARIUM.—Lettuce opium is the dried latex of lettuce. It occurs in hard, opaque, irregular pieces, often curved on one side. They are light green when fresh but become dull brown on keeping. The interior of fresh pieces may be whitish and soft, but darkens and hardens on keeping. Lactucarium yields nearly half its weight to water, forming a deep brown infusion. The odour is characteristic, recalling that of opium, and the taste is bitter. Lactucarium contains a colourless, tasteless, crystalline substance named lactucerin, or lactucone (about 50 per cent.); this is accompanied by the bitter principles, lactucin and lactucic acid, which are crystalline, and lactucopicrin, which is amorphous. Mannitol, sugar and caoutchouc are also present. Lactucarium is employed as a sedative for irritable cough, usually in pastilles and lozenges. **Dose.**—0·3 to 1 gramme (5 to 15 grains).

Preparations

Extractum Lactucae, B.P.C.—(*Ext. Lactuc.*)—Extract of Lettuce. A soft extract prepared from the expressed juice. **Dose.**—0·3 to 1 gramme (5 to 15 grains).

LÆVULOSUM

(Lævulos.)

Lævulose*Synonyms*—Fructose; Levulose.

Lævulose consists mainly of the monosaccharide, lævulose, together with small quantities of dextrose and water. It is found frequently in nature, accompanying dextrose in fruits and honey, or cane sugar in other plants. Lævulose may be prepared from "invert sugar," which is a mixture of equal parts of dextrose and lævulose prepared by the hydrolysis of sucrose with dilute sulphuric acid. Excess of acid is removed by treatment with barium carbonate and the evaporated liquid is cooled in ice and treated with calcium hydroxide which combines with the lævulose to form a sparingly soluble saccharate. The precipitate is removed and decomposed by carbon dioxide, the precipitated calcium carbonate filtered off and the filtrate allowed to crystallise or evaporated to dryness *in vacuo*. Lævulose may also be obtained from the inulin of dahlia tubers and chicory root by boiling with dilute mineral acids.

It occurs as an odourless, white or cream coloured, hygroscopic, crystalline powder with a sweet taste. The aqueous solution is lævorotatory and reduces Fehling's solution; the specific rotation of pure lævulose at 20°, in a well-boiled 10 per cent. solution, is -93.6° . When heated it becomes anhydrous, and melts at about 95° ; at 170° it is converted into the dextrorotatory compound, lævulosan, $\text{C}_6\text{H}_{10}\text{O}_5$, and at higher temperatures it swells up and burns, evolving an odour of burnt sugar and leaving a bulky, carbonaceous residue.

Very **soluble** in water and diluted alcohol; less soluble in alcohol (90 per cent.); insoluble in dehydrated alcohol and ether.

Standard, B.P.—Lævulose has a specific rotation, determined at 20° in a well-boiled 10 per cent. w/v aqueous solution and calculated on the substance dried at 105° , of not less than -81° . Loss on drying at 105° , not more than 5 per cent. Arsenic limit, 2 parts per million. Lead limit, 2 parts per million. Sulphated ash, not more than 2.5 per cent.

Action and Uses.—Lævulose is more easily assimilated than sucrose and has been recommended for use in such wasting diseases as phthisis, large quantities, 120 to 240 grammes (4 to 8 ounces), being given daily with tincture of quassia or other bitter. Lævulose, like other lævorotatory carbohydrates, is sometimes found to be assimilated by diabetics, when the usual carbohydrate foods increase the excretion of sugar in the urine and are therefore inadmissible. It is also recommended for administration to tuberculous children in place of lactose or sucrose. Lævulose is often used as a test of liver efficiency. Unless there is a definite lesion of the liver, lævulose does not raise the blood sugar concentration. 50 grammes in 100 millilitres of water is given by the

mouth and the blood sugar is determined at intervals of thirty minutes for two hours and compared with a sample taken before the ingestion of the lævulose.

LAPPA

(Lappa)

Burdock

Synonym—Burdock Root.

Burdock is the dried root of *Arctium majus* Bernh. (Fam. Compositæ) and of other species of *Arctium*, plants growing in Europe, Northern Asia and the United States of America. The roots are collected in the spring of the second year of their growth, before the flowers have appeared.

The root is simple, greyish-brown and usually occurs in pieces from 5 to 20 centimetres long and from 0·5 to 2 centimetres thick; it is sometimes split longitudinally, when the pieces assume a channelled form, frequently showing internally a whitish, lacunous tissue. Externally, the root is longitudinally wrinkled and bears the scars or small warty projections left by the removal of the small secondary roots; near the crown an indistinct annulation is sometimes seen and at the summit the felted-hairy remains of the leaf-bases may be present. The fracture is short and horny, the smoothed, transverse surface showing a light brown bark extending for about one quarter of the radius, then a dark cambium line surrounding a compact and indistinctly radiate xylem, which passes, towards the central quarter of the radius, into a white, parenchymatous region which has become lacunous by shrinkage. The odour is slight and the taste sweetish and mucilaginous.

Burdock **contains** inulin, fixed and volatile oils, pectin and sugar.

Standard.—Burdock contains not more than 5 per cent. of leaf-bases and stem and not more than 2 per cent. of other foreign organic matter.

Action and Uses.—Burdock is rarely used in medicine. It has been administered in the form of decoction (Decoctum Lappæ, 1 in 20) as a diuretic and diaphoretic, as much as a pint being given daily.

Dose.—1 to 6 grammes ($\frac{1}{4}$ to $1\frac{1}{2}$ drachms).

LARIX

(Larix)

Larch

Synonyms—Laricis Cortex; Larch Bark.

Larch is the bark obtained from *Larix europæa* DC. (Fam.

Pinaceæ), a tree indigenous to Southern and Central Europe and cultivated in Britain. The bark is stripped from the branches and dried. Young bark, or older bark deprived of its outer portion, is preferred.

The bark occurs in flat, curved or channelled pieces, rarely in quills. The outer bark, when not removed, is frequently largely developed, its outer surface is yellowish or dark brown and fissured, and it readily splits tangentially into flakes, disclosing a rose-coloured surface; the inner bark is narrow and whitish. The fracture is short and somewhat fibrous. The smoothed, transverse section shows a rhytidome built up of laminæ of reddish-brown cork separated by tangential plates of rose-pink tissue. The odour is terebinthinate and the taste is astringent, terebinthinate and rather bitter.

The diagnostic **microscopical** characters are the large, spindle-shaped and often irregular bast fibres, which may be as much as a millimetre in length, and certain long, narrow cells of the phloem parenchyma, each containing several small, prismatic crystals of calcium oxalate.

Larch **contains** tannin, and the crystalline bitter principle, larixin (larixinic acid), which appears to be allied to catechol. Larixin is said to be most abundant in the young bark.

Action and Uses.—Larch has been used internally as an expectorant in chronic bronchitis in the form of a tincture (Tinctura Laricis, 1 in 8; dose, 20 to 30 minims).

LAUROCERASUS

(*Laurocer.*)

Cherry-laurel

Synonyms—*Laurocerasi Folia*; Cherry-laurel Leaves.

Cherry-laurel consists of the fresh leaves of *Prunus Laurocerasus* Linn. (Fam. Rosaceæ), an evergreen shrub indigenous to Persia and Asiatic Turkey and cultivated in temperate regions.

The leaves are shortly petiolate, with a simple, coriaceous lamina, from 12 to 17 centimetres long and from 4 to 5 centimetres broad, oblong-lanceolate to oblong-obovate, the apex being acuminate and recurved. The margin is distantly serrate and slightly revolute; the upper surface is dark green and glossy, the lower surface paler. The midrib is prominent below and the venation is pinnate, the lateral veins anastomosing near the margin. One or two nectaries occur on the under surface at the base of the lamina on either side of the midrib. The leaves, when bruised, develop the characteristic odour of prussic acid and benzaldehyde.

Cherry-laurel **contains** the glycoside, prulaurasin (laurocerasin), which has been obtained in long, slender, acicular, bitter crystals, melting at 120° to 122°; it closely resembles amygdalin, but is not identical with it, prulaurasin being the glycoside of racemic mandelonitrile,

whereas amygdalin is the gentiobioside of α -mandelonitrile. It contains also the enzyme, prunase, which in contact with the prulaurasin decomposes it with formation of dextrose, hydrocyanic acid and benzaldehyde. The leaves yield, on an average, about 0.1 per cent. of hydrocyanic acid; young leaves yield more than old ones and unexpanded leaves may yield as much as 2.4 per cent

Action and Uses.—Cherry-laurel is used for the preparation of Aqua Laurocerasi, which is employed for internal and external use as a sedative, in place of dilute hydrocyanic acid. It is added to eye lotions (1 in 16), and is also prescribed as a flavouring agent.

Preparation

Aqua Laurocerasi, B.P.C.—(Aq. Laurocer.)—Cherry-laurel Water. *Syn.*—Aqua laurocerasi I.A. It is prepared by distillation from the fresh leaves, the product being adjusted to contain from 0.09 per cent. to 0.11 per cent. w/v of HCN. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

This water was included in the British Pharmacopœia, 1914

Aqua amygdalæ amaræ I.A. is prepared from bitter almond and contains 0.1 per cent. of hydrocyanic acid.

LAWSONIA

(Lawson.)

Henna

Synonym—Henna Leaf.

Henna consists of the dried leaves of *Lawsonia alba* Lam. (Fam. Lythraceæ), a shrub indigenous to Arabia and cultivated in Northern Africa, India and Ceylon.

The leaves are about 2.5 to 5 centimetres long and 1 to 2.5 centimetres broad, oval, greenish-brown or brown, and glabrous, having a short petiole, mucronate apex, entire and revolute margin, decurrent base, and pinnate venation, the lateral veins being curved and joining near the margin.

The diagnostic **microscopical** characters are the polygonal, tabular cells of the epidermis with striated cuticle; the cells of the mesophyll containing yellow colouring matter; the cluster-crystals of calcium oxalate measuring up to about 40 microns in diameter; 2 or sometimes 3 rows of palisade on each side; the absence of trichomes.

Henna **contains** fats, an ether-soluble resin, hennotannic acid and a colouring matter, lawson (2-hydroxy-1 : 4-naphthoquinone). It yields to water about 25 to 33 per cent. of extractive. The ash is from 7 to 10.5 per cent.

Standard.—Henna yields to water not less than 25 per cent. of extractive. Acid-insoluble ash, not more than 4 per cent. Boil 2

grammes for thirty minutes with 40 millilitres of water; in the decoction, boil for one hour 0.5 gramme of white knitting wool which has been washed in warm water containing a little ammonia, rinse the wool several times in water and dry; a fine Titian-red colour is imparted to the wool.

Uses.—Henna is used as a dye for the hair and for this purpose is often mixed with other substances.

LEPTANDRA

(Leptand.)

Leptandra

Synonyms—Black Root; Culvers Root.

Leptandra consists of the dried rhizome and roots of *Veronica virginica* Linn. (Fam. Scrophulariaceæ), a tall perennial herb, abundant in Eastern and Central North America.

The hard, woody rhizome occurs in pieces about 5 centimetres in length and one centimetre in diameter; it is dark greyish-brown in colour and bears brown cataphyllary leaves; its upper surface bears small buds and the remains of aerial stems, which are encircled by scale leaf scars and are usually cup-shaped at the ends. To the sides and under surface are attached numbers of stout roots which tend to divide into numerous fibrous pieces leaving the central strand of wood. The fracture is short; the smoothed, transverse surface shows a narrow, dark cortex, a paler ring of wood and a large dark pith. The odour is slight, and the taste bitter and acrid.

Leptandra **contains** an amorphous bitter substance, 3 : 4-dimethoxy cinnamic acid, mannitol, dextrose, verosterol, cinnamic and *p*-methoxycinnamic acids in the form of esters, and a mixture of fatty acids

Standard.—Leptandra contains not more than 5 per cent of its stem and other foreign organic matter. Acid-insoluble ash, not more than 6 per cent.

Leptandra, in powder (Pulvis Leptandræ : Pulv. Leptand.), contains the constituents of Leptandra, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Leptandra is a reputed cholagogue, and is said to promote the flow of bile without irritating the intestine. It has been recommended in chronic constipation. It may be administered as Extractum Leptandræ in pills, and is frequently combined with podophyllin or euonymin, extract of hyoscyamus or belladonna being added to prevent griping.

Dose.— 1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

Preparations

Extractum Leptandræ, B.P.C.—(Ext. Leptand.)—Extract of Leptandra. *Syn.*—Leptandrin. A dry extract. Dose.—0·03 to 0·12 gramme ($\frac{1}{2}$ to 2 grains).

Tabellæ Leptandræ Compositæ, B.P.C.—(Tab. Leptand. Co.)—Compound Tablets of Leptandra. *Syn.*—Tabellæ Laxativæ Compositæ; Vegetable Laxative Tablets. Each tablet contains 1 grain of compound extract of colocynth, $\frac{1}{2}$ grain each of extract of leptandra, jalap resin, resin of podophyllum, dry extract of hyoscyamus and extract of taraxacum, and oil of peppermint. Dose.—1 to 3 tablets.

LIMONIS CORTEX

(Limon. Cort.)

Lemon Peel

Lemon peel consists of the outer part of the fresh pericarp of *Citrus Limonia* Osbeck (Fam. Rutaceæ), a small tree cultivated in the countries bordering the Mediterranean Sea. The fruit is gathered when green, afterwards ripening and becoming yellow in colour.

Externally, lemon peel is pale yellow in colour, the surface being glabrous but somewhat rough owing to the presence of large oil glands just beneath the epidermis; internally, it is white and pithy. The odour is strong and fragrant and the taste is pleasantly bitter.

The diagnostic **microscopical** characters are the numerous large, ovoid, lysigenous oil glands in the yellowish tissue just beneath the epidermis; the lacunous parenchyma of the pithy portion, consisting of stellately-branched cells; the numerous prisms of calcium oxalate; the small, scattered vascular bundles. Lemon peel **contains** volatile oil and hesperidin.

Standard, B.P.—Lemon peel contains only a small amount of the white spongy part of the pericarp on the inner surface.

Action and Uses.—Lemon peel is a bitter stomachic, but is used more as a flavouring agent than for this property. Dried lemon peel may be used in tropical and subtropical parts of the Empire for making preparations when the fresh peel cannot be obtained.

LIMONIS CORTEX SICCATUS.—Dried lemon peel is the dried, outer part of the pericarp of *Citrus Limonia* Osbeck. The peel occurs in the form of spiral bands about 1·5 centimetres wide, 2 to 3 millimetres thick, and often 20 or more centimetres long; certain pieces show the nipple-shaped apex of the fruit. The outer surface is brownish-yellow, rough from the presence of projections over the oil glands, and often slightly concave; the inner surface is white or whitish and somewhat lacunous; there is present only a small part of this inner white portion of the pericarp. The peel is brittle, and possesses a pleasant, aromatic odour and a bitter, aromatic taste. Dried lemon peel is used for the same purposes as fresh lemon peel.

Preparations

Syrupus Limonis, B.P.—(Syr. Limon.)—Syrup of Lemon. It contains the alcohol-soluble matter of 6 per cent. w/v of lemon peel with citric acid and syrup. It should be stored in a cool place in a container previously washed with boiling water. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Syrupus Succı Limonis, B.P.C.—(Syr. Succ. Limon.)—Syrup of Lemon Juice. Lemon juice, about 1 in 2, with a tincture of lemon peel and sucrose Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This syrup was included in the British Pharmacopœia 1914, under the name of Syrupus Limonis.

Tinctura Limonis, B.P.—(Tinct. Limon.)—Tincture of Lemon. 1 in 4, by maceration with alcohol (60 per cent.). Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

LINUM

(*Linum*)

Linseed

Synonyms—*Linı Semina*: Flaxseed.

Linseed is the dried, ripe seeds of *Linum usitatissimum* Linn. (Fam. Linacæ), a tall, erect annual cultivated in most temperate and tropical regions. The fruit is a small, globular capsule containing about ten seeds which are separated when ripe.

The seeds are small, brown and glossy, with a minutely pitted surface; they are about 4 to 6 millimetres long and 2 to 2.5 millimetres in maximum width, elongated-ovoid and strongly flattened. They are rounded at one end and obliquely pointed at the other, near which, on one edge, is a slight depression in which both the hilum and the micropyle are situated. The embryo, consisting of two yellowish-white, flattened plano-convex cotyledons and a radicle, nearly fills the seed and is completely surrounded by a thin, whitish endosperm; both endosperm and embryo are oily. The drug is odourless and has a mucilaginous, oily taste.

The diagnostic **microscopical** characters are the isodiametric cells of the testa with mucilaginous outer walls; the cylindrical, collenchymatous cells of the middle layer of the seed coats; the single layer of yellowish-brown, longitudinally elongated, sclerenchymatous cells, about 120 to 190 microns long and 14 to 17 microns wide, with thick, lignified and pitted walls; the single layer of flattened, polygonal pigment cells with reddish-brown contents; the aleurone grains from the cotyledons, up to 20 microns in diameter, each with globoid and crystalloid; the abundant globules of fixed oil; the presence of an occasional starch grain.

Linseed **contains** from about 30 to 40 per cent. of fixed oil, about 6 per cent. of mucilage which occurs in the seed coat, and about 25 per cent. of proteins, together with wax, resin, sugar, phosphates, and a small quantity of the glycoside, linamarin (phaseolunatin). The unripe seeds contain an occasional starch grain.

Varieties.—The principal supplies are obtained from the Argentine, Russia, Canada, India, Holland, and the United States of America. Linseed varies somewhat in appearance according to its source. In general, warm climates yield larger and paler seeds than cold climates.

Substitute.—A variety of linseed with pale yellowish seed coats is known as white linseed. Powdered linseed cake, left after extracting the oil from the seeds by pressure, is sometimes known as "linseed meal"; it is distinguished from the pharmacopœial linseed meal by its low yield of fixed oil, which is usually about 6 to 8 per cent.

Standard, B.P.—Linseed contains not more than 2 per cent. of foreign organic matter

Action and Uses.—Linseed is used in the preparation of Infusum Lini, which is administered as a demulcent in the treatment of cough, especially those forms due to irritation of the pharynx and upper part of the respiratory passages. Infusion of linseed is also given as a demulcent drink in intestinal or urinary catarrhs, and a simple mucilage, prepared by pouring boiling water over linseed and straining, is used as an enema in cases of ulcerative colitis. Crushed linseed is used in the form of a poultice (Cataplasma Lini, Linseed Poultice), to apply warmth and moisture locally for the relief of superficial or deep-seated inflammation. The poultice mass may be prepared by adding 4 ounces of crushed linseed gradually to 10 fluid ounces of boiling water. It is usually enclosed in muslin, and the surface of the poultice may be smeared with oil to prevent it adhering to the skin.

Preparations

Infusum Lini, B.P.C.—(Inf. Lini)—Infusion of Linseed. About 1 in 30. Dose.—30 to 120 millilitres (1 to 4 fluid ounces).

Linum Contusum, B.P.—(Linum Contus.)—Crushed Linseed. *Syn.*—Lini Semina Contusa; Linseed Meal. Linseed, coarsely powdered, containing not less than 30 per cent. of fixed oil, and exhibiting only an occasional starch grain in the residue. Ash, not more than 5 per cent. It should be recently prepared.

Mucilago Lini, B.P.C.—(Mucil. Lini)—Mucilage of Linseed. 1 in 8.

LIQUOR AMMONIÆ FORTIS

(Liq. Ammon. Fort.)

Strong Solution of Ammonia

Strong solution of ammonia is an aqueous solution of ammonia, NH_3 (17.03), and may be prepared by heating a mixture of ammonium chloride and slaked lime and dissolving the resulting gas in water. It may be obtained from the ammoniacal liquors of gas works by distillation with slaked lime or synthetically from atmospheric nitrogen. Strong solution of ammonia occurs as a clear, colourless liquid with a very pungent, characteristic odour and a strongly alkaline reaction. It produces dense, white fumes when the vapour is brought into contact with the vapour of hydrochloric acid. It should be **stored** in well-stoppered bottles in a cool place.

Miscible with water in all proportions

Standard B.P.—Strong solution of ammonia contains not less

than 31·5 per cent. and not more than 33·5 per cent. w/w of NH_3 . Specific gravity, 0·885 to 0·891. Residue on evaporation to dryness on a water-bath, not more than 0·01 per cent. w/v. Arsenic limit, 0·5 part per million. Lead limit, 1 part per million. It complies also with a limit test for tarry matter.

Action and Uses.—Ammonia, when inhaled, excites the medulla and the fifth nerve endings, causing acceleration of the heart, stimulation of respiration, and some vasoconstriction. The rationale of smelling salts depends upon these reflex effects. Its effects are therefore similar to those of ammonium chloride—mildly expectorant, diaphoretic and diuretic. Ammonia is given **internally** in the form of *Liquor Ammonia Dilutus* or *Spiritus Ammonia Aromaticus*. Hypodermic injections of dilute solution of ammonia (2 to 6 minims) have been given for collapse. **Externally**, the dilute solution of ammonia is rubefacient and counter-irritant. It is used to neutralise insect stings; for snake bites it is injected into the site of the puncture and a dose may also be injected into the vein of the leg in urgent cases. In the form of liniment, it is used as a rubefacient and counter-irritant application for lumbago, joint affections, muscular pains, and in bronchitis; this preparation is known also as "hartshorn and oil." In the form of cloudy or household ammonia solution of ammonia is used as a cleansing agent for the skin and for domestic purposes generally; a suitable preparation may be prepared with 10 per cent. of ammonia and 1 per cent. of soap and is rendered opalescent by the addition of a soluble calcium salt.

The greatest care should be used in handling strong solution of ammonia, and in opening its containers; its concentrated vapour may cause inflammation of the air passages or spasm of the glottis with sudden death. In cases of **poisoning** by solutions of ammonia, vinegar, lemon juice, or acetic acid, freely diluted, should be given. Demulcent drinks should be taken freely and an injection of morphine given if necessary.

Preparations

Linimentum Ammonia, B.P.C.—(*Lin. Ammon.*)—Liniment of Ammonia. Dilute solution of ammonia, 25 per cent. v/v. with oleic acid and liquid paraffin.

This liniment replaces the liniment of the British Pharmacopœia, 1914, which contained 25 per cent. v/v of almond oil and 50 per cent. v/v of olive oil, in place of the oleic acid and liquid paraffin.

Liquor Ammonia Anisatus, B.P.C.—(*Liq. Ammon. Anisat.*)—Anisated Solution of Ammonia. *Syn.*—*Liquor Ammonii Anisatus*; *Spiritus Ammonia Anisatus*. Dilute solution of ammonia, 1 in 6, with oil of anise and alcohol (90 per cent.). Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

Liquor Ammonia Dilutus, B.P.—(*Liq. Ammon. Dil.*)—Dilute Solution of Ammonia. It contains 10 per cent. w/w of NH_3 (limits, 9·5 to 10·5). Specific gravity, 0·958 to 0·9615. Arsenic limit 0·10 part per million. Lead limit 0·3 part per million. Residue on evaporation to dryness on a water-bath, not more than 0·005 per cent. It complies also with a limit test for tarry matter. It should be stored in well-closed containers in a cool place. Dose.—0·6 to 1·2 millilitres (10 to 20 minims).

LIQUOR ANTIMONII CHLORIDI

(Liq. Antim. Chlorid.)

Solution of Antimonious Chloride*Synonym*—Butter of Antimony

Solution of antimonious chloride may be prepared by the action of hydrochloric acid on black antimony which has been purified until comparatively free from other metals, the clear solution being filtered and concentrated to the required specific gravity. It is a heavy liquid of a yellowish-red colour, this colour being partly due to the presence of large traces of iron. When mixed with excess of water, it deposits a white precipitate of antimony oxychloride

Standard.—Solution of antimonious chloride contains not less than 17 and not more than 18 per cent. w/w of Sb. Specific gravity, 1·465 to 1·475

Assay.—Mix about 0·5 millilitre, accurately weighed, with 20 millilitres of water, 5 grammes of sodium potassium tartrate and 2 grammes of sodium bicarbonate, and titrate with N/10 iodine; each millilitre of N/10 iodine is equivalent to 0·006088 gramme of Sb.

Uses.—Solution of antimonious chloride has been used as an escharotic for poisoned wounds and cancerous growths. It is now rarely used except in veterinary practice and in the manufacture of furniture polishes

LIQUOR ERGOSTEROLIS IRRADIATI

(Liq. Ergosterol. Irrad.)

Solution of Irradiated Ergosterol

Solution of irradiated ergosterol is a solution in arachis oil or other suitable vegetable oil of the product, or of the purified calciferol separated from it, obtained by irradiating a solution of ergosterol with ultra-violet light. Ergosterol, $C_{27}H_{41}OH, H_2O$, is a sterol obtained from yeast and also present in ergot. It may be dehydrated at 105° , but it quickly re-absorbs moisture from the air. It crystallises from alcohol in wide, monoclinic lamellæ, and from ether in monoclinic needles, melting between 162° and 164° . It is strongly lævorotatory. The irradiation may be carried out by surrounding a mercury vapour lamp with a spiral of silica tubing of 4 millimetres bore, through which a 0·3 per cent. solution of ergosterol in ether is allowed to pass at a rate of about 20 to 30 millilitres per minute. The solution of ergosterol before and after irradiation is kept in an atmosphere of nitrogen from which all traces of oxygen and carbon dioxide have been removed. The ether is removed by distillation under reduced pressure and the residue is treated with 90 per cent. alcohol when the greater part of the unchanged ergosterol remains undissolved.

Irradiated ergosterol is identified by its power to cure rickets produced experimentally in rats. It contains vitamin D, which has been isolated in pure, crystalline form and named calciferol. Calciferol melts between 114.5° and 117° ; its antirachitic activity is equivalent to 40,000 International units per milligram. It is strongly dextrorotatory. Solution of irradiated ergosterol should be **stored** in well-closed containers in a cool place and protected from light.

Standard, B.P.—Solution of irradiated ergosterol contains in 1 gramme approximately 3000 units of antirachitic vitamin (vitamin D). The unit of vitamin D is the activity contained in a specified quantity of a solution of irradiated ergosterol issued by the National Institute for Medical Research, London, and adopted as the International standard by the Permanent Commission on Biological Standardisation of the League of Nations. The assay of solution of irradiated ergosterol is conducted by a contemporary comparison with the standard by a biological method which depends on its power to promote calcification in the bones of rats. The assay process may utilise either the curative or the prophylactic effect of the vitamin.

Action and Uses.—Vitamin D is essential for the normal calcification of bones during growth (i.e., it prevents the development of rickets), and during maturity (i.e., it prevents the development of osteoporosis). The absence of vitamin D from the diet is said to increase liability to dental caries. The low levels of calcium and phosphorus of the blood in rickets and osteoporosis are brought back to normal by giving solution of irradiated ergosterol. An adequate amount of calcium salts and phosphorus compounds in the diet is essential during the administration of vitamin D. Overdosage should be avoided since mild toxic symptoms have been attributed to large doses. Continued overdosage may cause abnormal deposition of calcium in various tissues of the body. It has been stated that the toxic dose is not far removed from the optimal curative dose. Liability to toxic effects of large doses of solution of irradiated ergosterol appears to be greater in normal subjects than in rachitic patients.

Dose.—Prophylactic, 1000 to 3000 units daily for an infant (0.3 to 1 millilitre, 5 to 15 minims); curative, 5000 to 10,000 units daily for an infant (1.5 to 3 millilitres, 25 to 50 minims).

Preparations

Emulsio Olei Arachis, B.P.C.—(Emuls. Ol. Arach.)—Emulsion of Arachis Oil. *Syn.*—Marylebone Cream (Improved). Each fluid drachm contains about $\frac{1}{2}$ fluid drachm of arachis oil and solution of irradiated ergosterol equivalent to about 300 units of antirachitic activity. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Extractum Malti cum Vitaminis, B.P.C.—(Ext. Malt. c. Vitamin.)—Extract of Malt with Vitamins. Solution of vitamin A, 1 per cent. w/w, and solution of irradiated ergosterol, 1.5 per cent. w/w, in extract of malt. It is about 3 times as potent as extract of malt and cod-liver oil; 4 millilitres (1 fluid drachm) contains about 3000 units of vitamin A and 225 units of antirachitic activity (vitamin D). Dose.—8 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce)

LIQUOR FORMALDEHYDI

(Liq. Formaldehyd.)

Solution of Formaldehyde*Synonym*—Formalin.

Solution of formaldehyde is an aqueous solution of formic aldehyde, HCHO (30·02), containing some methyl or ethyl alcohol, or both, to prevent polymerisation of the formaldehyde to solid paraformaldehyde, $(\text{CH}_2\text{O})_n$. The general use of the synonym "formalin" is limited to Great Britain and Northern Ireland. Formaldehyde itself is a colourless, extremely irritating gas which is obtained by the dry distillation of calcium formate or by the catalytic oxidation of the vapour of methyl alcohol.

Solution of formaldehyde occurs as a colourless liquid with a characteristic, pungent, irritating odour and a burning taste. It reduces ammoniacal silver nitrate solution, yields hexamine when treated with solution of ammonia, and a formate when boiled with an alkali. When a trace of a dilute solution of formaldehyde is added to a solution containing 1 per cent. w/v of phenylhydrazine hydrochloride and a small quantity of potassium ferricyanide strongly acidified with hydrochloric acid, a brilliant red colour is produced. When two drops of solution of formaldehyde are added to sulphuric acid mixed with a small quantity of salicylic acid, a deep red colour is produced. When mixed with an equal volume of sodium hydroxide solution and boiled with resorcinol, formaldehyde yields a yellow colour, changing to red. When evaporated to dryness on a water-bath, solution of formaldehyde yields a white residue of paraformaldehyde. It should be **stored** in well-closed containers, in a moderately warm place.

Standard, B.P.—Solution of formaldehyde contains not less than 37 per cent. and not more than 41 per cent. w/v of CH_2O . Specific gravity, 1·080 to 1·095. It is neutral or slightly acid to litmus.

Action and Uses.—Solution of formaldehyde is a very powerful germicide; diluted with 200 parts of water it kills most micro-organisms. It reacts with proteins and when undiluted it has a caustic action on the tissues. Applied undiluted to the skin, it hardens it, ultimately rendering it impermeable. As a germicide, solution of formaldehyde is considered to be as effective as mercuric chloride, but owing to its irritant and destructive action its use is limited. Continuous inhalation of formaldehyde causes inflammation of the respiratory tract and may result in bronchitis and pneumonia. Undiluted solution of formaldehyde is sometimes applied to small patches of ringworm. A 1 or 2 per cent solution of Liquor Formaldehydi in water has been used as a paint or spray in diphtheria and ozæna, while 1 part with 3 parts of glycerin is sometimes used as a paint in lupus vulgaris. As a mouth-wash or gargle, 1 part in 500 parts of water is suitable. A 0·05 per cent. solution of Liquor Formaldehydi in water may be used as an eye lotion. Solution of formaldehyde is used for disinfecting excreta, but it is not suitable for

preserving urine for subsequent examination. *Liquor Formaldehydi Saponatus*, suitably diluted, may be used as an antiseptic solution for instruments.

For the disinfection of rooms, solution of formaldehyde may be used with a spray. The gas may be liberated readily from the solution by adding 50 grammes of potassium permanganate or 100 grammes of chlorinated lime to each 100 millilitres. It is stated that the gas liberated from 5 ounces of the solution is sufficient to disinfect completely 1000 cubic feet of air space when the room is closed for ten hours. The solid polymeride may be used if vaporised with a suitable lamp, instead of the solution (see *Paraformaldehydum*). Formaldehyde solution does not injure metals or fabrics. A 2 per cent. solution in water is used as a preservative for pathological specimens. This is preferable to alcohol because the specimens retain their colour. As a hardening agent for microscopical purposes, a 4 per cent. aqueous solution is used. For preserving corpses for dissection, a 10 per cent. solution is commonly used. A 1 in 5 dilution may be applied to insect bites; a 1 in 20 dilution exposed in a shallow container is said to kill flies. When a 1 per cent. solution of formaldehyde is prescribed, 1 volume of *Liquor Formaldehydi* diluted to 100 volumes with water should be dispensed.

Formaldehyde renders protein less susceptible to the action of pepsin. Advantage is taken of this fact in the preparation of glutoid capsules. These consist of gelatin which has been dipped in formaldehyde solution. Solution of formaldehyde is **incompatible** with ammonia and oxidising agents. **Poisoning** by formaldehyde is characterised by severe pain throughout the alimentary tract, which may be followed by collapse and death; in non-fatal cases the liver and kidneys may become affected. Poisoning by inhalation produces pneumonia and bronchitis. Treatment consists of the use of the stomach pump or an emetic and administration of aromatic spirit of ammonia.

Preparation

Liquor Formaldehydi Saponatus, B.P.C.—(*Liq. Formaldehyd. Sap.*)—Solution of Formaldehyde with Soap. Soft soap, 1 in 2½, and solution of formaldehyde, 1 in 5, in alcohol (90 per cent.) and distilled water

This solution was included in the British Pharmacopœia 1914.

LIQUOR GLYCERYLIS TRINITRATIS

(*Liq. Glyc. Trinit.*)

Solution of Glyceryl Trinitrate

Synonyms—*Solutio nitroglycerini spirituosa I.A.*; *Liquor Trinitrin*; *Solution of Trinitrin*; *Solution of Nitroglycerin*; *Spiritus Glycerilis Nitratis*.

Solution of glyceryl trinitrate is a solution of glyceryl trinitrate in alcohol (90 per cent.). Glyceryl trinitrate, $C_3H_5(NO_3)_3$ (227.1), is the nitric acid ester of glycerin and is prepared by treating dehydrated

glycerin with a mixture of fuming nitric acid and sulphuric acid. After purification, glyceryl trinitrate is obtained as an odourless, colourless liquid with a sweet, aromatic, pungent taste. It solidifies at 8° and, in the solid condition, is dangerous to handle, readily exploding on percussion and sometimes spontaneously. While liquid, contact with a flame neither ignites nor explodes it, but contact with red-hot iron does. When absorbed by diatomite it constitutes the explosive, dynamite. The name "Liquor Glonoini" is sometimes used for solution of glyceryl trinitrate.

Solution of glyceryl trinitrate occurs as a clear, colourless liquid, neutral to litmus, and having a specific gravity of 0.836 to 0.841. It yields a turbid mixture when mixed with twice its volume of distilled water, the glyceryl trinitrate being thrown out of solution and, after standing, separating as an oily liquid. In contact with alkalis the glyceryl trinitrate is slowly decomposed and, on the subsequent addition of potassium iodide solution and dilute sulphuric acid, iodine is liberated and brown fumes evolved.

Standard, B.P.—Solution of glyceryl trinitrate contains not less than 0.9 per cent. and not more than 1.1 per cent. w/v of $C_3H_5(NO_3)_3$. Alcohol content, 88 to 90 per cent. v/v of ethyl alcohol.

Action and Uses.—Glyceryl trinitrate is absorbed unaltered by the stomach, and is supposed to be converted into nitrite in the body. The action of glyceryl trinitrate resembles that of amyl nitrite, but is less rapidly produced and is more prolonged. Solution of glyceryl trinitrate is employed to reduce blood pressure in arterial degeneration and chronic nephritis. It is also given to relieve spasmodic asthma, the difficult breathing of acute bronchitis, and in some forms of vomiting, including sea-sickness, and is used in angina pectoris, but its use should be avoided in the angina due to coronary thrombosis. Tolerance of the drug is soon established and, after long-continued use, as much as 4 millilitres (1 fluid drachm) has been given. Glyceryl trinitrate is often administered in the form of *Tabella Glycerylis Trinitratis* which should be chewed, not swallowed whole.

Dose.—0.03 to 0.12 millilitre ($\frac{1}{2}$ to 2 minims).

Preparation

Tabella Glycerylis Trinitratis, B.P.—(Tab. Glyc. Trinit.)—Tablet of Glyceryl Trinitrate. *Syn.*—*Tabellæ Trinitrin*; Trinitrin Tablets; Tablets of Nitroglycerin. Each tablet contains 0.0005 gramme (about $\frac{1}{200}$ grain) of glyceryl trinitrate in a chocolate basis. Dose.—1 or 2 tablets.

LIQUOR HYDROGENII PEROXIDI

(Liq. Hydrog. Perox.)

Solution of Hydrogen Peroxide

Synonym—Liquor Hydrogenii Dioxidii.

Solution of hydrogen peroxide is an aqueous solution of hydrogen

peroxide, H_2O_2 (34.02), and may be prepared by the action of dilute sulphuric acid upon barium peroxide suspended in water, at a temperature below 10° . It occurs as a colourless, odourless liquid, with a slightly acid taste. It is comparatively stable in the presence of a slight excess of acid, but it readily decomposes when rendered alkaline and when in contact with oxidisable substances or certain metals. When heated, it decomposes with evolution of oxygen. When one drop is shaken with a mixture of ether and an acidified solution of potassium chromate, the ethereal layer, after separation, is coloured blue. Solution of hydrogen peroxide is met with in commerce as 10, 12, 20 and 30 "volume", the number indicating the volumes of oxygen obtainable from one volume of the preparation. A 100 volume solution is also obtainable, containing 30 per cent. w/v of H_2O_2 , and is more stable than the weaker forms. It should be **stored** in a bottle made of neutral glass, closed with a glass stopper or a paraffined cork, in a cool place, and protected from light.

Standard, B.P.—Solution of hydrogen peroxide contains not less than 2.5 per cent. and not more than 3.5 per cent. w/v of H_2O_2 , corresponding to about 10 times its volume of available oxygen. Residue on evaporation on a water-bath, not more than 0.2 per cent. w/v. It complies also with limit tests for barium and for acidity.

Action and Uses.—Solution of hydrogen peroxide owes its efficacy as an antiseptic and disinfectant to the readiness with which it liberates oxygen in the presence of living or dead tissue and bacteria. It does not combine with albumin, and is non-poisonous. It is applied locally to wounds, and used to cleanse discharging ulcers, abscesses, and venereal sores. It is also used as drops for the ear, often with an equal volume of alcohol (95 per cent.) or industrial methylated spirit, and stronger solutions are employed in dental practice to cleanse septic cavities, etc. In washing out empyemal or serous cavities, care is necessary on account of the large volume of oxygen rapidly liberated.

For external use in skin diseases, it may be applied mixed with glycerin and rose water, or a cream may be prepared with anhydrous wool fat and 2 per cent. of the solution. A 1 in 8 solution may be used as a spray to the throat in diphtheria and scarlet fever, and as a disinfectant gargle or mouth-wash. A 1 in 10 solution has been used as an eye lotion. Diluted with water (1 in 4) it has been used to arrest epistaxis, and as a wash to brush the teeth and destroy dental discharges. It is occasionally used internally, when it should be well diluted. It is also used to bleach hair and delicate fabrics. Strong solutions of the peroxide produce irritating "burns" on the skin, but the pain disappears in about an hour and no blister is left. It is **incompatible** with most organic substances and with alkalis, iodides, permanganates and oxidisable substances.

Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

ETHER OZONICUS.—Ozonic ether is an ethereal solution of hydrogen peroxide prepared by shaking a strong solution of the peroxide with ether and separating the ethereal layer. With potassium permanganate solution and dilute sulphuric acid it yields about five volumes of oxygen. It is not miscible with water, but mixes readily with alcohol. Ozonic ether is occasionally given in mixtures in the treatment of whooping cough, solution being effected by the addition of alcohol. It may be used as a test for blood; when some freshly prepared tincture of guaiacum is added to a liquid containing traces of blood, the subsequent addition of ozonic ether causes the formation of a blue oxidation product, which colours the ethereal layer. Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

LIQUOR VITAMINÆ-A

(Liq. Vitamin. A)

Solution of Vitamin A

Solution of vitamin A is a solution in arachis oil or other suitable vegetable oil of a concentrate obtained from mammalian or other suitable livers. It may be prepared by the following process. The liver is chopped up and saponified with alcoholic potash; the unsaponifiable matter is extracted with ether, care being taken to prevent oxidation, the ether is removed, and the residue dissolved in twice its weight of methyl alcohol and cooled to 0°, when most of the cholesterol crystallises out and is removed; finally the methyl alcohol is removed by distillation.

A concentrate so prepared from mammalian livers contains a very small amount of vitamin D, but may contain more vitamin A than a concentrate prepared in the same way from cod-liver oil. The concentrate is dissolved in the oil and the solution diluted to the required strength. A guide to the vitamin A content may be obtained by applying the antimony trichloride test as described in the British Pharmacopœia and determining the relative concentration which gives 5 blue units in a Lovibond tintometer. The "blue value" is the number of blue units, calculated from the result, that would be given by 0.04 gramme of substance. The vitamin A content of preparations may also be standardised by spectrographic means, either by measuring the intensity of absorption of the characteristic band in the ultra-violet portion of the spectrum, or by measuring the intensity of absorption of either or both of the two bands in the visible spectrum produced by the action of antimony trichloride on the vitamin. It should be **stored** in well-closed containers, in a cool place and protected from light.

Standard.—Solution of vitamin A contains in 1 gramme approximately 60,000 units. The unit of vitamin A is the vitamin A activity of 0.001 milligram of a sample of carotene kept in the National Institute for Medical Research, London, and provisionally adopted as the International standard by the Permanent Commission on Biological Standardisation of the League of Nations. The assay of a solution of vitamin A is conducted biologically by a contemporary comparison with the standard.

Action and Uses.—The mode of action of vitamin A is unknown. Its deficiency in the diet leads to general degenerative changes in the epithelium of the alimentary canal, which cause defective absorption. Inflammatory changes in the structure of the eye, known as xerophthalmia, are also produced, and can be cured by the administration of this vitamin. There is often a general lowering of the resistance of the body, particularly of the respiratory tract, to infective agents. Vitamin A has, in fact, been called the anti-infective vitamin. It has been shown experimentally that diets rich in vitamin A prevent degeneration of the spinal cord which occurs when diets containing ergot are eaten. Lathyrism in dogs fed on *Lathyrus sativus* may be prevented by giving yellow maize which is rich in vitamin A, but not by white maize which is almost devoid of vitamin A.

Therapeutically, vitamin A is indicated for children during the period of growth, for women during pregnancy and lactation, and to increase resistance to bacterial infection. This vitamin has been given as a prophylactic against puerperal sepsis in doses of 10,000 units daily throughout pregnancy, or 50,000 units daily during the last month of pregnancy. For the treatment of puerperal sepsis, 450,000 units daily in twelve doses may be given; as a general safeguard against infections of the respiratory tract, 5000 to 15,000 units may be given.

Dose.— 5000 to 50,000 units

Preparation

Extractum Malti cum Vitaminis, B.P.C.—(Ext. Malt. c Vitamin.)—Extract of Malt with Vitamins. Solution of vitamin A, 1 per cent. w/w, and solution of irradiated ergosterol, 1.5 per cent. w/w, in extract of malt. It is about 3 times as potent as extract of malt and cod-liver oil; 4 millilitres (1 fluid drachm) contains about 3000 units of vitamin A and 225 units of antirachitic activity (vitamin D). **Dose.**— 8 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

LITHII ACETYSALICYLAS

(Lith. Acetylsalicyl.)

Lithium Acetylsalicylate

Lithium acetylsalicylate, $\text{CH}_3\text{CO}\cdot\text{OC}_6\text{H}_4\cdot\text{COOLi}$, may be prepared by neutralising a solution of acetylsalicylic acid in an organic solvent with lithium carbonate and precipitating the salt by the addition of ether. It occurs as a slightly hygroscopic powder, decomposing in moist air. The aqueous solution is gradually hydrolysed, forming lithium salicylate and acetic acid. It should be **stored** in well-stoppered bottles.

Soluble in water (1 in 1) and alcohol (1 in 4).

Standard.—Lithium acetylsalicylate, determined by the method for Lithii Citras, contains not less than 95 per cent. of $\text{C}_6\text{H}_7\text{O}_4\text{Li}$; 1 gramme

of Li_2SO_4 is equivalent to 3.384 grammes of $\text{C}_9\text{H}_7\text{O}_4\text{Li}$. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million.

Action and Uses.—The action of lithium acetylsalicylate is virtually that of acetylsalicylic acid. On account of its gradual hydrolysis in aqueous solutions it is best **administered** in powders, cachets or tablets.

Dose.—0.3 to 1 gramme (5 to 15 grains).

LITHII BENZOAS

(Lith. Benz.)

Lithium Benzoate

Lithium benzoate, $\text{C}_6\text{H}_5\cdot\text{COOLi}$, may be prepared by stirring lithium carbonate into distilled water and adding a sufficient quantity of benzoic acid to the warmed liquid. The resulting solution is filtered, evaporated to a small bulk, allowed to crystallise, and the crystals dried at the ordinary temperature, or the solution may be evaporated and the residue dried at 30° to 35° . It occurs as a light, white powder or in small, shining, crystalline scales, odourless or with a slight benzoin-like odour, and having a sweetish, saline taste. It is slightly unctuous to the touch. On heating, the salt fuses, and at a higher temperature it carbonises, giving off inflammable vapours having a benzoin-like odour; on complete ignition, it leaves a white residue of lithium carbonate, which has an alkaline reaction and colours a non-luminous flame crimson. A 10 per cent. aqueous solution gives with ferric chloride solution a buff-coloured precipitate, and with dilute hydrochloric acid a white crystalline precipitate of benzoic acid.

Soluble in water (about 1 in 3), boiling water (about 1 in 2), alcohol (1 in 15), and boiling alcohol (1 in 10).

Standard.—Lithium benzoate, determined by the method of the British Pharmacopœia for Sodii Benzoas, contains not less than 98.5 per cent. of $\text{C}_7\text{H}_5\text{O}_2\text{Li}$; each millilitre of N/2 sulphuric acid is equivalent to 0.06399 gramme of $\text{C}_7\text{H}_5\text{O}_2\text{Li}$. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. It complies with the limit tests for chlorides, sulphates and chlorinated compounds in Sodii Benzoas.

Action and Uses.—Lithium benzoate resembles in its action the benzoates of sodium and potassium. It is antiseptic and diuretic, and is employed in cystitis and gonorrhœa. The acid radical is excreted as hippuric acid in the urine and therefore this salt of lithium does not render the urine less acid, as does the citrate. Although formerly credited with limiting uric acid formation it has no such action. Lithium benzoate is commonly **administered** in mixture form, or enclosed in a cachet to be swallowed with a large draught of water.

Dose.—0.3 to 1 gramme (5 to 15 grains).

LITHII BROMIDUM

(Lith. Brom.)

Lithium Bromide

Lithium bromide may be prepared by neutralising a hot solution of hydrobromic acid with lithium carbonate. The solution obtained, which must be faintly acid after all carbon dioxide is driven off, is filtered and evaporated, and the residue dried at 120° . It may be obtained in crystals by evaporating its syrupy solution over concentrated sulphuric acid. The amount of water of crystallisation varies according to the temperature of crystallisation, but the commercial salt contains less than one molecule. It occurs as a more or less granular, very deliquescent, odourless, white, crystalline powder, having a somewhat sharp and bitter taste. On heating, the salt fuses, and slowly volatilises as the temperature is raised.

Soluble in water (5 in 3), boiling water (10 in 3), alcohol and ether-alcohol.

Standard.—Lithium bromide, determined by the method of the British Pharmacopœia for Potassii Bromidum, and calculated on the substance dried at 160° , contains not less than 98 per cent. of LiBr; each millilitre of N/10 silver nitrate is equivalent to 0.008686 gramme of LiBr. Loss, on drying at 160° , not more than 15 per cent. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. 1 gramme complies with the limit test for sulphates. It complies with the limit tests for bromate, barium, chloride, and alkali in Potassii Bromidum. 1 millilitre of chloroform, shaken with a solution of 0.5 gramme in 10 millilitres of water and 2 drops of ferric chloride solution, does not acquire a violet colour (limit of iodide).

Action and Uses.—Lithium bromide has similar properties to potassium bromide, but is liable to cause digestive disturbances. It is used in epilepsy and gout. It is best **administered** in mixture form, flavoured with aromatic syrup.

Dose.—0.3 to 1 gramme (5 to 15 grains).

LITHII CARBONAS

(Lith. Carb.)

Lithium Carbonate

Lithium carbonate may be obtained by various processes from lepidolite and other mineral ores containing lithium. It occurs as a white, odourless, amorphous powder, or in minute, crystalline grains, having a slightly alkaline taste. Its aqueous solution is alkaline to litmus. On heating to dull redness, it melts to a transparent liquid, losing a

portion of its carbon dioxide and becoming partly converted into oxide. Moistened with hydrochloric acid and heated on a platinum wire it imparts a crimson colour to the flame.

Soluble in water (1 in 80) and boiling water (1 in 140); more soluble in water containing carbon dioxide; insoluble in alcohol

Standard.—Lithium carbonate contains not less than 98·5 per cent. of Li_2CO_3 , calculated on the substance dried at 100° . Loss on drying at 100° , not more than 1 per cent. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. 1 gramme dissolved in 10 millilitres of dilute nitric acid complies with the limit test for chlorides. 1 gramme dissolved in 10 millilitres of dilute hydrochloric acid complies with the limit test for sulphates. Dissolve 1 gramme in 30 millilitres of N/1 hydrochloric acid and neutralise with solution of ammonia, filter if necessary and divide into two portions: to one portion add 1 millilitre of ammonium oxalate solution; no turbidity or precipitate is produced on standing for five minutes (limit of calcium); to the second portion add 1 millilitre of sodium phosphate solution; no precipitate is produced on standing for five minutes (limit of magnesium)

Assay.—Dissolve about 1 gramme, accurately weighed, in 50 millilitres of N/1 sulphuric acid and titrate the excess of acid with N/1 sodium hydroxide, using methyl orange as indicator; each millilitre of N/1 sulphuric acid is equivalent to 0·03694 gramme of Li_2CO_3 .

Action and Uses.—Lithium carbonate resembles the carbonates of sodium and potassium in its action. It is diuretic and has been employed to increase the alkalinity of the blood and to prevent the deposition of insoluble urates or to remove deposits already formed. It is, however, extremely doubtful whether, in the concentration obtained, lithium salts have any action in this latter direction. The urates of lithium are more soluble than the corresponding salts of sodium or potassium, and it is upon this fact that the use of lithium salts in gout and rheumatism is founded. Its employment in medicine has no rational foundation, since the soluble urate cannot exist either in the body or in the urine in the presence of sodium and potassium ions. Lithium carbonate is **administered** in the form of lithia water, or in dilute solution in distilled water, copious draughts being taken, preferably on an empty stomach.

Dose.—0·12 to 0·3 gramme (2 to 5 grains).

LITHII CHLORIDUM

(Lith. Chlorid.)

Lithium Chloride

$\text{LiCl} = 42·40$

Lithium chloride may be prepared by neutralising hydrochloric acid

with lithium carbonate, or by decomposing an aqueous solution of lithium sulphate with barium chloride. When the solution is evaporated to dryness the anhydrous salt is produced, but if evaporated slowly over concentrated sulphuric acid the salt, $\text{LiCl} \cdot \text{H}_2\text{O}$, may be obtained. Lithium chloride occurs in white, octahedral crystals, or more frequently as a crystalline powder, or in masses, which are deliquescent, and have a taste similar to that of sodium chloride. It forms a crystalline compound with alcohol. Evaporation of an aqueous solution is accompanied by slight decomposition, traces of hydrochloric acid being lost and the solution becoming alkaline. At a red heat it fuses to a clear liquid, giving off some chlorine; at a higher temperature it is volatilised. Alcohol dissolves lithium chloride from an admixture with sodium and potassium chlorides. It should be **stored** in well-closed containers.

Readily **soluble** in water (2 in 3), alcohol (1 in 30) and ether-alcohol.

Standard.—Lithium chloride, determined by the method of the British Pharmacopœia for Sodii Chloridum, contains not less than 99 per cent. of LiCl , calculated on the salt dried at 100° ; each millilitre of N/10 silver nitrate is equivalent to 0.004240 gramme of LiCl . Loss on drying at 100° , not more than 5 per cent. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. 1 gramme complies with the limit test for sulphates.

Action and Uses.—Lithium chloride has the typical salt action of the chlorides of the alkali metals, but is rarely used medicinally. It is diuretic and is occasionally employed in very dilute solution in gout and rheumatism. A 2 per cent. w/v solution in water is used for medical ionisation.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

LITHII CITRAS

(Lith. Cit.)

Lithium Citrate

Lithium citrate may be prepared by neutralising a solution of citric acid with lithium carbonate, filtering and crystallising the solution. It occurs in somewhat deliquescent, odourless, white crystals, having a cooling, slightly saline taste. The aqueous solution is faintly alkaline to litmus. Lithium citrate loses three-fourths of its water of crystallisation at 100° , but requires a temperature of 150° to 160° to render it anhydrous. Heated to redness it chars, giving off inflammable vapours and finally leaving a white residue of lithium carbonate. When too high a temperature is used during incineration, some of the carbonate is converted to oxide.

Soluble in water (1 in 2); almost insoluble in alcohol and ether.

Standard.—Lithium citrate contains not less than 98·5 per cent. of $C_6H_5O_7Li_3 \cdot 4H_2O$. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. 1 gramme complies with the limit tests for chlorides and sulphates.

Assay.—Ignite about 1 gramme, accurately weighed, add an excess of sulphuric acid, re-ignite and weigh the residue of Li_2SO_4 ; 1 gramme of residue is equivalent to 1·710 gramme of $C_6H_5O_7Li_3 \cdot 4H_2O$.

Action and Uses.—Lithium citrate resembles in its action the citrates of sodium and potassium, and is excreted in the urine as carbonate. It increases the alkalinity of the blood, and renders the urine less acid. For the reasons stated under Lithii Carbonas, it is largely employed in gout and rheumatism, being often preferred to the carbonate on account of its greater solubility in water. It is **administered** in solution with large draughts of water, in tablets dissolved in water, or as Lithii Citras Effervescens.

Dose. - 0·3 to 0·6 gramme (5 to 10 grains).

Preparation

Lithii Citras Effervescens, B.P.C.—(Lith. Cit. Efferv.)—Effervescent Lithium Citrate. About 1 in 20. Dose.—4 to 8 grammes (1 to 2 drachms).

Effervescent lithium citrate was included in the British Pharmacopœia, 1914.

LITHII IODIDUM

(Lith. Iod.)

Lithium Iodide

$LiI = 133·9$

Lithium iodide may be prepared by neutralising a solution of hydriodic acid with lithium carbonate, filtering, evaporating, and drying the residue at 100° to 105°. It occurs as irregular, deliquescent, odourless, white or yellowish-white masses, and has a bitter, saline taste. On keeping it becomes yellowish in colour and should be **stored** in well-closed containers. The aqueous solution is neutral or faintly alkaline, and on concentration over sulphuric acid deposits crystals of the composition, $LiI \cdot 3H_2O$, which melt between 72° and 73°.

Readily **soluble** in water and alcohol.

Standard.—Lithium iodide, determined by the method of the British Pharmacopœia for Potassii Iodidum, contains not less than 99 per cent. of LiI , calculated on the salt dried at 120°; each millilitre of M/20 potassium iodate is equivalent to 0·01339 gramme of LiI . Loss on drying at 120°, not more than 10 per cent. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million.

Action and Uses.—Lithium iodide resembles in its properties the iodides of potassium and sodium. It is occasionally employed in place of these salts in chronic gout and rheumatism, and is administered in dilute aqueous solution. It is also employed in aqueous solution (25 per cent.) in pyelography.

Dose.—0·06 to 0·3 gramme (1 to 5 grains).

LITHII SALICYLAS

(Lith. Salicyl.)

Lithium Salicylate

Lithium salicylate, $\text{C}_6\text{H}_4(\text{OH})\cdot\text{COOLi}$, may be prepared by heating on a water-bath, to a temperature not above 60° , a mixture of lithium carbonate, salicylic acid and water. The resulting liquid is evaporated at about 60° , and the residue dried. Lithium salicylate occurs as an odourless, white or greyish-white, hygroscopic, crystalline powder, which exhibits needle-shaped crystals under the microscope, and has a nauseating, sweet taste. The aqueous solution should be colourless, with a faintly acid reaction. On heating, the salt decomposes, emitting an odour of phenol and leaving an alkaline residue.

Soluble in water (4 in 3), alcohol (1 in 2) and ether.

Standard.—Lithium salicylate, determined by the method of the British Pharmacopœia for Sodii Salicylas, contains not less than 98·5 per cent. of $\text{C}_7\text{H}_5\text{O}_3\text{Li}$, calculated on the salt dried at 120° ; each millilitre of N/2 sulphuric acid is equivalent to 0·07198 gramme of $\text{C}_7\text{H}_5\text{O}_3\text{Li}$. Loss on drying at 120° , not more than 3 per cent. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. It complies with the limit tests for free acid, chloride and sulphate in Sodii Salicylas.

Action and Uses.—Lithium salicylate has properties resembling those of sodium salicylate. The salicylic radical temporarily increases the excretion of uric acid, besides relieving the pain and stiffness of rheumatic joints. A 30 per cent. w/v solution of lithium salicylate in doses up to 4 millilitres (60 minims) is used as a sclerosing agent for the injection treatment of varicose veins; a local anæsthetic is sometimes added. Lithium salicylate is best **administered** in aqueous solution, well diluted. It is incompatible with alkali carbonates, free ammonia and acids

Dose.—0·6 to 2 grammes (10 to 30 grains).

LOBELIA

(Lobel.)

Lobelia*Synonyms*—*Lobelia herba* I.A.; Indian Tobacco.

Lobelia consists of the dried, aerial parts of *Lobelia inflata* Linn. (Fam. Campanulaceæ), an erect, annual herb indigenous to, and cultivated in, the Eastern United States of America. The plant is cut down when the lower fruits are nearly ripe, and dried.

The stems are green in colour, often with a purplish tint, rounded, hairy and winged in the upper part, channelled, angled and nearly glabrous below; they bear unicellular hairs up to about 1.2 millimetres in length and alternate leaves or leaf-scars. The leaves are pale green, broadly ovate to ovate-lanceolate in outline and vary in length from about 3 to 8 centimetres; the margin is irregularly toothed and the lamina bears scattered, bristly hairs, especially on the veins of the lower surface. The fruit is an inflated, ovoid or ellipsoidal, bilocular capsule, containing, when ripe, numerous brown, ovoid, reticulate seeds about 0.5 to 0.7 millimetre long and about 0.3 millimetre wide. *Lobelia* has a slight and somewhat irritating odour; the taste, which is at first slight, becomes burning and acrid when the drug is chewed.

The diagnostic **microscopical** characters are the elongated-polygonal, highly refractive, lignified, anticlinal walls of the seed epidermis; the conical, unicellular, or rarely 2-celled, trichomes with thin, warty walls and usually about 300 microns, but sometimes as much as 1.2 millimetres, long; the straight-walled, papillose, upper epidermal cells of the leaves; the abundant minute drops of oil scattered throughout the mesophyll; the anastomosing laticiferous vessels of the stem and leaf; the lignified and pitted parenchyma of the pith; the water-pores, usually about 9 in number, on the upper surface of most of the teeth of the leaves; the spherical pollen grains with smooth extine and three pores.

Lobelia contains lobeline, $C_{22}H_{27}O_2N$, lobelanine, lobelanidine and a number of other alkaloids; the most important is lobeline. The drug also contains a neutral, crystalline substance, inflatin, and lobelic acid.

Standard, B.P.—*Lobelia* contains not more than 60 per cent. of stems and not more than 2 per cent. of foreign organic matter. Acid-insoluble ash, not more than 5 per cent.

Lobelia, in powder (*Pulvis Lobeliae* : *Pulv. Lobel.*), contains the constituents and possesses the diagnostic microscopical characters of *Lobelia*, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—*Lobelia* is used for its action in depressing the vasomotor centre and peripheral vagus, thus producing dilatation of the bronchioles by relaxing the bronchial muscles. Lobeline has an action very closely resembling that of nicotine; it first excites nerve cells and then paralyzes them. It has been used as an antidote to poisoning by opium, barbitone, carbon monoxide, etc., in asphyxia during surgical

anæsthesia, and in the paralysis of the respiratory centre occurring during lumbar anæsthesia. For these purposes it may be administered by intramuscular injection in doses of 0.003 to 0.009 gramme ($\frac{1}{30}$ to $\frac{2}{30}$ grain). The stimulation is pronounced, but transient.

Lobelia is given in spasmodic asthma, in the dyspnœa of chronic bronchitis, and in other affections of the respiratory passages; it should not be employed when there is cardiac disease. Lobelia is also used as an expectorant in laryngeal and bronchial catarrh. Its action in spasmodic asthma is enhanced by combination with sodium iodide or bromide. Large doses are diuretic, cathartic and emetic, and may cause collapse through medullary paralysis. It is an ingredient of *Pulvis Lobeliæ Compositus* and other powders intended to be burnt for the relief of asthma, but the use of such powders is not to be recommended owing to the vicious circle set up by the irritant fumes resulting from combustion. For internal use, the simple tincture and ethereal tincture are administered. In cases of **poisoning** by lobelia, the stomach should be evacuated and stimulants given.

Dose.—0.2 to 0.6 gramme (3 to 10 grains).

Preparations

Mistura Lobeliæ et Stramonii Composita, B.P.C.—(Mist. Lobel. et Stramon. Co.)—Compound Mixture of Lobelia and Stramonium. Each fluid ounce contains 4 grains of ammonium carbonate, 5 grains of potassium iodide and 10 minims each of ethereal tincture of lobelia and tincture of stramonium, in chloroform water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Pulvis Lobeliæ Compositus, B.P.C.—(Pulv. Lobel. Co.)—Compound Lobelia Powder. Equal parts of lobelia, stramonium and tea, impregnated with potassium nitrate and oil of anise.

Pulvis Stramonii Compositus, B.P.C.—(Pulv. Stramon. Co.)—Compound Stramonium Powder. Stramonium, 1 in 2, with lobelia, anise and tea, impregnated with potassium nitrate and oil of eucalyptus.

Tinctura Lobeliæ Ætherea, B.P.—(Tinct. Lobel. Æther.)—Ethereal Tincture of Lobelia. 1 in 5, by percolation with spirit of ether. Dose.—0.3 to 1 millilitre (5 to 15 minims).

Tinctura Lobeliæ Simplex, B.P.C.—(Tinct. Lobel. Simp.)—Simple Tincture of Lobelia. *Syn.*—Tinctura Lobeliæ. 1 in 8, in alcohol (60 per cent.) Dose.—0.6 to 2 millilitres (10 to 30 minims).

Tinctura Lobeliæ I.A. is prepared with alcohol (70 per cent.) from 10 per cent. w/w of lobelia.

LUPULINUM

(Lupulin.)

Lupulin

Lupulin consists of the glandular trichomes separated from the strobiles of *Humulus Lupulus* Linn. (Fam. Cannabinaceæ). The glands, which are distributed over the bases of the bracts, over the

perigones, and, to a less degree, over the stipules, may be separated by shaking and beating the hops and sifting the resulting powder.

The drug forms a granular, golden-yellow powder, which darkens with age to yellowish-brown. The odour is strong and characteristic, valerian-like in old samples, and the taste is bitter and aromatic. **Microscopically**, the glands are more or less rounded in shape, 100 to 250 microns in diameter; the lower portion consists of a single, hemispherical, concave layer of cells, the delicate cuticle of which has been raised by the oleo-resinous secretion to form a domed covering.

Lupulin **contains** about 3 per cent. of volatile oil, which consists chiefly of the sesquiterpene, humulene, together with various oxygenated bodies, to which the oil owes its peculiar odour. Other constituents are the crystalline principles, humulone and lupulone, the yellow crystalline principles, xanthohumol and choline, resin and wax.

Adulterants.—Inferior qualities of lupulin often consist of sweepings from the floors of hop kilns.

Standard.—Lupulin yields not more than 40 per cent. of ether-insoluble matter. Ash, not more than 14 per cent.

Action and Uses.—Lupulin is an aromatic bitter, and is reputed to be mildly sedative. It is occasionally **administered** as a hypnotic in pills, with dilute alcohol as an excipient, or in capsules or cachets.

Dose.—0.12 to 0.3 gramme (2 to 5 grains).

LUPULUS

(Lupul.)

Lupulus

Synonyms—Hops; Humulus; Strobili Lupuli.

Lupulus consists of the dried strobiles of the hop plant, *Humulus Lupulus* Linn. (Fam. Cannabinaceæ), collected from cultivated plants. The hop is a dioecious, climbing plant, growing in Europe generally, and largely cultivated in South-Eastern England, Belgium, Germany, Russia, California, etc. Lupulus should be **stored** in closed containers and protected from light.

The strobiles are about 3 centimetres long, and ovoid or flattened-ovoid in shape. They consist of a hairy, zigzag axis, 12 to 16 millimetres long, carrying a number of imbricated, pale yellowish-green, ovate, membranous bracts and stipules, the bracts being twice as numerous as the stipules. In the axil of each bract is a small achenial fruit, over which the margin is folded; the stipules are flat, and without fruits. The bracts and stipules are about 15 to 30 millimetres long and 5 to 10 millimetres wide. The perigones and the bases of both the bracts and stipules are sprinkled with minute, shining glands (see Lupulinum).

Recently dried lupulus possesses a bitter, aromatic taste and a strong characteristic, aromatic odour which gradually becomes distinctly unpleasant as the drug is kept, the change being ascribed to the oxidation of the resin with production of valeric acid; on this account, only recently dried material should be used, which can be recognised by its odour and distinct greenish colour.

Lupulus **contains** volatile oil, of which it yields about 0.3 to 1.0 per cent. (specific gravity, 0.840 to 0.890; optical rotation, -1° to $+2^{\circ}$; refractive index, 1.470 to 1.495). Light petroleum extracts a soft resin (7 to 14 per cent.), and ether, a hard resin. The bitterness appears to be due to a number of substances, of which two, lupulone and humulone, have been obtained crystalline. Lupulus also contains a yellow, crystalline body, xanthohumol, a saturated acid, lactic acid, together with hentriacontane, ceryl alcohol and cerotic acid. The leafy organs contain about 5 per cent. of tannin, which is not a constituent of the glands.

Standard.—Lupulus contains not more than 2 per cent. of foreign organic matter. Acid-insoluble ash, not more than 5 per cent.

Action and Uses.—Lupulus has the action of the aromatic bitters. The infusion is employed as a vehicle, especially for bitters and tonics; the tincture is stomachic, and is used to improve the appetite and digestion. Both preparations were formerly believed to be sedative, and were given in nervousness and hysteria, and at bedtime to induce sleep. Lupulus is also made up into pillows, on the supposition that it induces sleep; any such action must be attributed to suggestion rather than to any effect of the volatile principles. Preparations of lupulus are **incompatible** with mineral acids and metallic salts.

Preparations

Extractum Lupuli, B.P.C.—(Ext. Lupul.)—Extract of Lupulus. *Syn.*—Extract of Hops. A soft extract. Dose.—0.3 to 1 gramme (5 to 15 grains).

Infusum Lupuli Concentratum, B.P.C.—(Inf. Lupul. Conc.)—Concentrated Infusion of Lupulus. *Syn.*—Concentrated Infusion of Hops. About 1 in $2\frac{1}{2}$. When infusion of lupulus or Infusum Lupuli is prescribed, this concentrated infusion diluted with seven times its volume of distilled water may be dispensed. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Tinctura Lupuli, B.P.C.—(Tinct. Lupul.)—Tincture of Lupulus. *Syn.*—Tincture of Hops. 1 in 5. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

LYCOPODIUM

(*Lycopod.*)

Lycopodium

Lycopodium consists of the spores of the common club moss, *Lycopodium clavatum* Linn. (Fam. Lycopodiaceæ), a creeping plant

indigenous to Europe, Asia and North America. It is collected chiefly in Russia, during July and August, by beating and shaking the plants and sifting the powder thus obtained. It should be **stored** in well-closed containers to prevent the development of mould.

Lycopodium is a pale yellow, very mobile powder, having a density of about 1·06 to 1·09, but which, because of the peculiar structure of its surface, floats upon water without becoming wet. When blown into a flame, it burns with a brilliant flash, but in a crucible it burns slowly. When rubbed between the fingers it is characteristically smooth and devoid of grittiness. 1 milligram of the powder consists of about 94,000 spores. Examined **microscopically**, the spores are seen to be very uniform in shape and size, the maximum width varying from 21 to 30 microns, being most commonly about 25 microns. Each spore has the shape of a triangular pyramid with a convex base, and is, in fact, the fourth part of a sphere which has been divided by plane surfaces radiating from its centre. The convex surface is covered with a fine network of raised ridges, the meshes being four to six-sided; the three flat, triangular faces have a similar network near the bases, but are nearly smooth towards the apex of the spore; strong ridges mark the lines of union of the flat faces. When crushed, the ruptured spores yield small drops of fixed oil, which stains red with tincture of alkanna.

Lycopodium **contains** about 50 per cent. of fixed oil, which consists chiefly of lycopodium-oleic acid with a little glyceryl myristate. The oil can be obtained by triturating the lycopodium with fine sand or pumice stone, and extracting with ether. Other constituents are sugar, traces of alkaloidal matter, and a phytosterol.

Substitutes and Adulterants.—Starch, pine pollen, resin, mineral matter and other substances have been used to adulterate lycopodium. Pine pollen, collected in Hungary, is known as *Lycopodium Hungaricum*.

Standard.—Lycopodium yields not more than 3 per cent. of ash. Moisture, not more than 5 per cent.

Action and Uses.—Lycopodium is employed in dispensing as a covering for pills. It does not absorb moisture, and affords some protection to pills composed of hygroscopic substances. It is used as a dusting powder for the skin, to soothe inflamed surfaces and reduce friction. On account of its lightness, it is a convenient diluent for insufflations for the throat, nose and ear; it is also employed as the basis for medicated snuffs. Tincture of lycopodium has been prescribed for incontinence of urine, and to allay spasm and irritation of the bladder. Lycopodium is used in quantitative microscopy.

Preparation

Tinctura Lycopodii, B.P.C.—(Tinct. Lycopod.)—Tincture of Lycopodium, 1 in 10. Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

MAGENTA

(Magent.)

Magenta

Synonyms—Fuchsine; Basic Fuchsine; Rosaniline Hydrochloride.

Magenta (Colour Index No. 677) is a mixture of pararosaniline (Colour Index No. 676) (hydrochloride of triaminotriphenylcarbinol anhydride) and rosaniline (hydrochloride of triaminodiphenyltolylcarbinol anhydride), and may be prepared by heating a mixture of aniline, *o*-toluidine and *p*-toluidine and their hydrochlorides with nitrobenzene, or a mixture of nitrobenzene and *o*-nitrotoluene in the presence of iron or zinc chloride. It occurs in glistening, iridescent, green crystals. The aqueous solution becomes yellow on the addition of hydrochloric acid, and a reddish precipitate of rosaniline bases separates on the addition of ammonia or milk of lime. The aqueous solution is decolourised on agitation with ammonia solution and zinc dust.

Soluble in water and alcohol, forming deep red solutions; more soluble in amyl alcohol; insoluble in ether.

Standard.—Magenta leaves not more than 5 per cent. of sulphated ash. Arsenic limit, 10 parts per million. Lead limit, 50 parts per million. Dissolve the sulphated ash from 1 gramme in 20 millilitres of water and 2 millilitres of dilute hydrochloric acid, and add 1 millilitre of potassium ferrocyanide solution; no precipitate is formed (limit of zinc).

Action and Uses.—Magenta is used chiefly in the form of carbol-fuchsin, as a reagent in microscopy for the detection of *B. tuberculosis*. It is also employed as a colouring agent, and a 1 per cent. ointment has been used in the treatment of impetigo.

ACID FUCHSINE (Colour Index No. 692) is a mixture of the sodium or ammonium salts of the di- and trisulphonic acids of magenta. It is soluble in water and alcohol.

MAGNESII BOROCITRAS

(Mag. Borocit.)

Magnesium Borocitrate

Magnesium borocitrate may be prepared by stirring a mixture of magnesium oxide, 3 parts, powdered boric acid, 3 parts, and powdered citric acid, 10 parts, with distilled water, 4 parts, to form a pasty mass. This hardens in a short time, and may be powdered; or it may be spread on glass plates and scaled. Magnesium borocitrate occurs as a white powder or in colourless, shining scales, having a bitterish taste and a weak acid reaction.

Slowly and completely **soluble** in water, more quickly soluble on heating. A small quantity of water converts it into a turbid liquid, but with a larger quantity it dissolves to form a clear solution.

Action and Uses.—Magnesium borocitrate is employed as a urinary antiseptic in chronic cystitis. It is **administered** in mixture form or in cachets. Pulvis Magnesii Borocitratis Compositus is more palatable, and is similarly employed. A mixture of magnesium borocitrate, 1 part, and sucrose, 2 parts, is known as borocite.

Dose.—1 to 2 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ drachm).

Preparation

Pulvis Magnesii Borocitratis Compositus, B.P.C.—(Pulv. Mag. Borocit. Co.)—Compound Magnesium Borocitrate Powder. Magnesium borocitrate, 1 in 3, with sucrose. **Dose.**—2 to 4 grammes ($\frac{1}{2}$ to 1 drachm).

MAGNESII CARBONAS LEVIS

(Mag. Carb. Lev.)

Light Magnesium Carbonate

Light magnesium carbonate is a hydrated, basic magnesium carbonate of variable composition, but corresponding approximately with the formula, $3\text{MgCO}_3 \cdot \text{Mg}(\text{OH})_2 \cdot 3\text{H}_2\text{O}$. It may be prepared by the following process:—Dissolve 125 parts of magnesium sulphate in 1000 parts of cold distilled water; add a cold solution of 150 parts of sodium carbonate in 1000 parts of distilled water and boil for fifteen minutes; collect the precipitate, wash with boiling water until the washings are free from sulphate, and dry at a temperature not exceeding 100° . Light magnesium carbonate occurs as a very light, white, stable powder, which is odourless and almost tasteless.

Almost **insoluble** in water and alcohol (90 per cent.).

Standard, B.P.—Light magnesium carbonate leaves on ignition not less than 42 per cent. and not more than 45 per cent. of residue. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. It complies also with limit tests for soluble matter, copper, calcium, chloride, sulphate and iron.

Action and Uses.—Light magnesium carbonate is antacid and laxative, resembling light magnesium oxide in its action. It is, however, less effective than the oxide, and has the disadvantage of liberating carbon dioxide. The light variety of magnesium carbonate is more suitable as an antacid and, for this reason, when magnesium carbonate is prescribed in mixtures, the light carbonate should be used, but when prescribed in powders or cachets, the heavy carbonate is more convenient. Light magnesium carbonate may be **administered** in powder form or in suspension in milk or water. It is often given with magnesium sulphate in the form of Mistura Alba, and is employed for subdividing volatile oils in inhalations, but should not be used with compound tincture of benzoin.

Dose.—0.6 to 4 grammes (10 to 60 grains).

MAGNESII CARBONAS PONDEROSUS

(Mag. Carb. Pond.)

Heavy Magnesium Carbonate

Heavy magnesium carbonate is a hydrated, basic magnesium carbonate of variable composition, but corresponding approximately with the formula, $3\text{MgCO}_3 \cdot \text{Mg}(\text{OH})_2 \cdot 4\text{H}_2\text{O}$. It may be prepared by the following process:—Dissolve 125 parts of magnesium sulphate in 250 parts of boiling distilled water; add a solution of 150 parts of sodium carbonate in 250 parts of boiling distilled water. Evaporate the mixed liquids to dryness, and digest the residue for thirty minutes with 500 parts of boiling distilled water; collect the precipitate, wash with boiling distilled water until the washings are free from sulphate, and dry at a temperature not exceeding 100° . Heavy magnesium carbonate occurs as a white, granular powder which is odourless and almost tasteless.

Almost **insoluble** in water and alcohol (90 per cent.).

Standard, B.P.—Heavy magnesium carbonate leaves on ignition not less than 42 per cent. and not more than 45 per cent. of residue. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. It complies also with limit tests for soluble matter, copper, calcium, chloride, sulphate and iron.

Action and Uses.—The medicinal properties of heavy magnesium carbonate closely resemble those of the light variety, but its smaller bulk renders it more convenient in use. It is **administered** in mixtures, cachets or powders. In the treatment of hyperchlorhydria, mixtures of calcium carbonate, sodium bicarbonate, bismuth carbonate and magnesium carbonate are used. The proportions of calcium and magnesium carbonate can be so adjusted that neither a purgative nor a constipating effect is produced. *Liquor Magnesii Bicarbonatis* is a mild laxative and antacid suitable for children; the slight bitterness of the liquid may be masked by the addition of sugar, or an acid syrup, effervescence occurring in the latter case.

Dose.—0.6 to 4 grammes (10 to 60 grains).

Preparations

Liquor Magnesii Bicarbonatis, B.P.—(Liq. Mag. Bicarb.)—Solution of Magnesium Bicarbonate. *Syn.*—Fluid Magnesia. It contains not less than 2.5 per cent. w/v of $\text{Mg}(\text{HCO}_3)_2$. 60 millilitres contains the equivalent of about 1 gramme, and 2 fluid ounces about 15 grains, of magnesium carbonate. Arsenic limit, 0.2 part per million. Lead limit, 0.5 part per million. It complies also with limit tests for alkali, chloride and sulphate. It should be stored in well-closed containers in a cool place. **Dose.**—30 to 60 millilitres (1 to 2 fluid ounces).

Liquor Magnesii Citratis, B.P.C.—(Liq. Mag. Cit.)—Solution of Magnesium Citrate. *Syn.*—Limonade Purgative; Effervescing Solution of Magnesium and Potassium Citrates. A solution containing carbon dioxide and magnesium citrate prepared with citric acid and 4 per cent. w/v of magnesium carbonate, flavoured with syrup of lemon. **Dose.**—100 to 300 millilitres ($3\frac{1}{2}$ to 10 fluid ounces), or more.

Pulvis Bismuthi Compositus, B.P.C.—(Pulv. Bism. Co.)—Compound Bismuth Powder. Bismuth carbonate, 1 part; calcium carbonate, 3 parts; heavy magnesium carbonate, 3 parts; sodium bicarbonate, 1 part. Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

Trochisci Alkalini Compositi, B.P.C.—(Troch. Alk. Co.)—Compound Alkaline Lozenges. Each lozenge contains 12 grains of compound bismuth powder.

MAGNESII CHLORIDUM

(Mag. Chlorid.)

Magnesium Chloride

Magnesium chloride may be prepared by neutralising hydrochloric acid with magnesium oxide or carbonate and crystallising. It occurs in colourless, transparent, deliquescent crystals. When heated in air, water is evolved, and at the same time partial decomposition occurs with evolution of hydrochloric acid and formation of oxychloride. The anhydrous salt, MgCl_2 , may be obtained by heating magnesium ammonium chloride.

Soluble in water (about 2 in 1) and alcohol (1 in 6).

Standard.—Magnesium chloride yields a clear solution when 2 grammes is dissolved in 10 millilitres of alcohol (85 per cent.). Arsenic limit, 2 parts per million. Lead limit, 5 parts per million. 1 gramme complies with the limit test for sulphates. 1 gramme in 25 millilitres of 20 per cent. sulphuric acid yields, on the addition of 50 millilitres of alcohol (95 per cent.) and allowing to stand overnight, not more than 0.04 gramme of CaSO_4 (limit of calcium).

Action and Uses.—Magnesium chloride has been used as a mild purgative in constipation and in intestinal dyspepsia.

Dose.—8 to 30 grammes ($\frac{1}{4}$ to 1 ounce).

MAGNESII BROMIDUM.—Magnesium bromide, $\text{MgBr}_2 \cdot 6\text{H}_2\text{O}$, is a colourless crystalline compound, soluble in water. It has an action similar to that of potassium bromide. Dose.—0.3 to 1.2 grammes (5 to 20 grains).

MAGNESII GLYCEROPHOSPHAS

(Mag. Glycerophosph.)

Magnesium Glycerophosphate

Synonym—Magnesium Glycerylphosphate.

Magnesium glycerophosphate, $\text{MgC}_3\text{H}_5(\text{OH})_2\text{PO}_4 \cdot 2\text{H}_2\text{O}$, may be

prepared by neutralising glycerophosphoric acid with magnesium carbonate. It occurs as a white, amorphous powder. Magnesium glycerophosphate is sometimes sophisticated by the addition of citric acid in order to render it more soluble. It is almost entirely **soluble** in cold water (about 1 in 50).

Standard.—Magnesium glycerophosphate contains not less than 97 per cent. of $C_3H_7O_6PMg$, calculated on the substance dried at 130° . Loss on drying at 130° , not more than 16 per cent. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. Dissolve 0.5 gramme in 10 millilitres of water acidified with sulphuric acid, add 2 millilitres of mercuric sulphate solution, boil and, if necessary, filter while hot; the hot filtrate, on the addition of potassium permanganate solution drop by drop, does not produce a white precipitate (limit of citrate). 1 gramme dissolves almost entirely in 50 millilitres of water, leaving not more than a slight residue, which completely dissolves on the addition of 0.2 millilitre of glycerophosphoric acid. When shaken with 25 parts of dehydrated alcohol and filtered, it yields on evaporation of the alcohol, and subsequent drying at 70° for one hour, not more than 1 per cent. of residue (limit of glycerin, etc.). A weight equivalent to 1 gramme of the substance dried at 130° , dissolved in 100 millilitres of water, requires for neutralisation to phenolphthalein not more than 2 millilitres of N/10 hydrochloric acid or of N/10 sodium hydroxide (limit of alkalinity or acidity). The neutralised solution requires not less than 9.8 millilitres of N/2 hydrochloric acid for neutralisation to methyl orange (minimum limit for glycerophosphate).

Assay.—Ignite about 0.5 gramme, accurately weighed, and weigh the residue; 1 gramme of the residue is equivalent to 1.746 gramme of $C_3H_7O_6PMg$.

Action and Uses.—Magnesium glycerophosphate has the general properties of the glycerophosphates (see Acidum Glycerophosphoricum), and is used for its glycerophosphate content rather than for the small proportion of magnesium present. It may be **administered** in solution in water flavoured with syrup of orange or orange-flower water. The salt is **incompatible** with alkali carbonates.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

MAGNESII HYDROXIDUM

(Mag. Hydrox.)

Magnesium Hydroxide

Synonym—Magnesium Hydrate.

Magnesium hydroxide may be prepared by boiling light magnesium oxide with from 20 to 30 times its weight of water for about twenty

minutes, draining and drying in thin layers at a temperature not exceeding 100°. It occurs as a white, amorphous powder, which differs from calcined magnesia by the greater readiness with which it dissolves in dilute acids.

Insoluble in water.

Standard.—Magnesium hydroxide yields on ignition not less than 67 per cent. and not more than 70 per cent. of residue. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. It complies with the limit tests for soluble matter, copper, calcium, chloride, sulphate and iron in *Magnesii Carbonas Levis*, the quantity taken for each test being three-fifths of the respective quantities of *Magnesii Carbonas Levis*.

Action and Uses.—Magnesium hydroxide is used as an antacid in gastric acidity and flatulence, in place of the alkali bicarbonates. It neutralises acidity with greater readiness than the oxides of magnesia, and has the advantage over carbonates that carbon dioxide is not evolved, and hence it does not cause an increased secretion of hydrochloric acid. It may be **administered** in tablets, powders or cachets, and may be suitably combined with powdered charcoal and carminatives. *Mistura Magnesii Hydroxidi* is usually the form in which the hydroxide is given. This preparation is also employed as a mouth-wash to neutralise the acids arising from fermentation around the teeth, the teeth and gums being brushed with the undiluted liquid at bedtime; it also serves as a useful antidote in cases of poisoning by mineral acids or arsenic.

Dose.—0·6 to 4 grammes (10 to 60 grains).

Preparations

Emulsio Paraffini Liquidi Alkalina, B.P.C.—(Emuls. Paraff. Liq. Alk.)—Alkaline Emulsion of Liquid Paraffin. Mixture of magnesium hydroxide, 25 per cent. v/v, with emulsion of liquid paraffin with agar. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Mistura Bismuthi et Magnesii Hydroxidum, B.P.C.—(Mist. Bism. et Mag. Hydrox.)—Mixture of Bismuth and Magnesium Hydroxides. Equal parts of mixture of bismuth hydroxide and mixture of magnesium hydroxide. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Mistura Magnesii Hydroxidi, B.P.—(Mist. Mag. Hydrox.)—Mixture of Magnesium Hydroxide. *Syn.*—Cream of Magnesia. An aqueous suspension of hydrated magnesium oxide, containing the equivalent of 8·25 per cent. w/v of $Mg(OH)_2$ (limits, 7·75 to 8·75). 16 millilitres contains the equivalent of 0·9 gramme, and 4 fluid drachms the equivalent of about 12½ grains, of magnesium oxide. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

This mixture was included in the British Pharmaceutical Codex, 1923.

Mistura Magnesii Hydroxidi et Paraffini Liquidi, B.P.C.—(Mist. Mag. Hydrox. et Paraff. Liq.)—Mixture of Magnesium Hydroxide and Liquid Paraffin. Liquid paraffin, 30 per cent. v/v, and mixture of magnesium hydroxide, flavoured with vanillin. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

MAGNESII OXIDUM LEVE

(Mag. Oxid. Lev.)

Light Magnesium Oxide*Synonyms*—Magnesia Levis; Light Magnesia.

Light magnesium oxide may be prepared by heating light magnesium carbonate to dull redness. It occurs as a very light, white, odourless powder, with a slightly alkaline taste. On exposure to the air it rapidly absorbs moisture and carbon dioxide. With fifteen times its weight of water it forms a gelatinous mass on standing for about thirty minutes. When heated strongly, it gives out a clear, white light. Light magnesium oxide should be **stored** in well-closed containers.

Almost **insoluble** in water and alcohol (90 per cent.).

Standard, B.P.—Light magnesium oxide loses on ignition not more than 5 per cent. of its weight. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. It complies also with limit tests for copper, calcium, chloride, sulphate, iron and soluble matter.

Action and Uses.—Light magnesium oxide is employed as an antacid and laxative, especially for children. It neutralises the acidity of the stomach in dyspepsia and heartburn, allays sickness, especially the vomiting of pregnancy, and renders the secretions less acid in gouty and rheumatic conditions. In the intestine it acts as a mild laxative, but, if repeatedly administered, concretions may be formed in the intestines. The neutralising value of magnesium oxide is more than twice that of magnesium carbonate and about four times that of sodium bicarbonate. Light magnesium oxide may be **administered** in powder form or in suspension in milk or water, but for administration in mixtures containing sodium bicarbonate the carbonates are preferred. The light variety of magnesium oxide is more suitable as an antacid than the heavy variety on account of its greater bulk and, for this reason, when magnesium oxide is prescribed in mixtures, the light oxide should be used, but when prescribed in powders or cachets, the heavy oxide is more convenient. Light magnesium oxide is also used as a dentifrice to neutralise acid secretions and to clean the teeth. It is **incompatible** with acids.

Dose.—0.6 to 4 grammes (10 to 60 grains).

MAGNESII OXIDUM PONDEROSUM

(Mag. Oxid. Pond.)

Heavy Magnesium Oxide*Synonyms*—Magnesia Ponderosa; Heavy Magnesia.

Heavy magnesium oxide may be prepared by heating heavy magnesium carbonate to dull redness. It occurs as a white, odourless

powder, with a slightly alkaline taste. On exposure to the air, it absorbs moisture and carbon dioxide. It does not form a gelatinous mass when allowed to stand in contact with water. It dissolves in dilute acids, forming solutions of magnesium salts. Heavy magnesium oxide should be **stored** in well-closed containers.

Almost **insoluble** in water and alcohol (90 per cent.).

Standard, B.P.—Heavy magnesium oxide loses on ignition not more than 5 per cent. of its weight. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. It complies also with limit tests for soluble matter, copper, calcium, chloride, sulphate and iron.

Action and Uses.—The medicinal properties of heavy magnesium oxide closely resemble those of the light variety, but its smaller bulk renders it more convenient in use. It may be **administered** in mixtures, cachets, or powders.

Dose.—0.6 to 4 grammes (10 to 60 grains).

MAGNESII PEROXIDUM

(*Mag. Perox.*)

Magnesium Peroxide

Magnesium peroxide may be prepared by adding solution of hydrogen peroxide to magnesium oxide, and keeping them in contact at the ordinary temperature for a day or two. The mixture is then filtered and the residue washed and dried at 100° to 105°. It occurs as a white, tasteless powder, having an alkaline reaction. It is more stable than hydrogen peroxide at a temperature of 100°; at about 300°, however, it loses all its active oxygen. It gives the reactions of hydrogen peroxide, including the characteristic blue colour on the addition of diluted sulphuric acid and a dichromate. Dilute acids liberate oxygen from magnesium peroxide.

Standard.—Magnesium peroxide contains not less than 15 per cent. of MgO_2 . Arsenic limit, 5 parts per million. Lead limit, 20 parts per million

Assay.—Weigh accurately 0.5 gramme into a flask, add 10 millilitres of water and 2.5 grammes of potassium iodide; allow the iodide to dissolve, add 10 millilitres of sulphuric acid (25 per cent.) and allow to stand for ten minutes; titrate the liberated iodine with N/10 sodium thiosulphate; each millilitre of N/10 sodium thiosulphate is equivalent to 0.002816 gramme of MgO_2 .

Action and Uses.—Magnesium peroxide is an oxidising agent and disinfectant. It has been employed to arrest gastric and intestinal fermentation. In the treatment of typhoid fever. 10 grain

doses every three or four hours have been found of service. Magnesium peroxide is **administered** in cachets, or the powder may be mixed with water; as an intestinal antiseptic it is best given in glutoid capsules. It is a useful antiseptic for the mouth, and may, with advantage, be added to tooth powders. Oxygenated tooth powder (Magnesii Peroxidum cum Creta) may be prepared with 10 per cent. of magnesium peroxide and 2.5 per cent. of hard soap in precipitated chalk suitably flavoured.

Dose.— 2 to 4 grammes ($\frac{1}{2}$ to 1 drachm).

MAGNESII PHOSPHAS

(Mag. Phosph.)

Magnesium Phosphate

Synonym—Tribasic Magnesium Phosphate.

Magnesium phosphate is the hydrated, tribasic magnesium phosphate, $Mg_3(PO_4)_2$, containing about 30 per cent. of combined water, and may be prepared by the interaction of magnesium sulphate and trisodium phosphate in aqueous solution. It forms a dry, slightly gritty, white powder, free from musty odour, and loses part of its water when dried at 100° . A less stable product, prepared by crystallisation below 36° , contains up to 60 per cent. of combined water and, unless kept at a low, even temperature, it is liable to develop growths of mould, as a result of evaporation followed by condensation of water.

Insoluble in water

Standard.—Magnesium phosphate, determined by the residue on ignition, contains not less than 68 per cent. of $Mg_3(PO_4)_2$. Arsenic limit, 5 parts per million. Lead limit, 25 parts per million. 1 gramme with 3 millilitres of nitric acid complies with the limit test for chlorides. 0.25 gramme with 2 millilitres of hydrochloric acid complies with the limit test for sulphates. 1 gramme diffused in 10 millilitres of water dissolves without effervescence on the addition of 5 millilitres of hydrochloric acid (limit of carbonate), and leaves not more than a slight residue.

Action and Uses.—Magnesium phosphate has antacid and mildly laxative properties. It is said to be superior to magnesium carbonates, hydroxide and oxides, and the alkali carbonates, in that it reduces the excess of acid in the stomach without producing systemic alkalisation. Magnesium phosphate is best **administered** in a little water. It is sometimes given with calcium phosphate to counteract any excessive aperient action produced by giving the magnesium compound alone.

Dose.— 1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

MAGNESII SALICYLAS

(Mag. Salicyl.)

Magnesium Salicylate

Magnesium salicylate, $(\text{C}_6\text{H}_4\text{OH}\cdot\text{COO})_2\text{Mg}\cdot 4\text{H}_2\text{O}$, may be prepared by neutralising a hot solution of salicylic acid with iron-free magnesium carbonate, filtering and evaporating the solution (in which the acid should be in slight excess) to crystallisation. It occurs in colourless, silky needles, or as a white or slightly pink, crystalline powder, with a sweetish but somewhat bitter taste. Heated to somewhat over 100° , it loses its water of crystallisation.

Readily **soluble** in water and alcohol.

Standard.—Magnesium salicylate, determined by the method of the British Pharmacopœia for Sodii Salicylas, contains not less than 99 per cent. of $\text{C}_{14}\text{H}_{10}\text{O}_6\text{Mg}$, calculated on the salt dried at 110° ; each millilitre of N/2 sulphuric acid is equivalent to 0·07460 gramme of $\text{C}_{14}\text{H}_{10}\text{O}_6\text{Mg}$. Loss on drying at 110° , not less than 19 per cent. and not more than 21 per cent. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million.

Action and Uses.—Magnesium salicylate has properties resembling those of the alkali salicylates, and has been used in typhoid fever and to disinfect the alimentary canal, but it is less readily absorbed than the alkali salicylates. It may be given in cachets, or in solution in water. It is **incompatible** with acids and alkali carbonates.

Dose.—0·5 to 2 grammes (8 to 30 grains).

MAGNESII SULPHAS

(Mag. Sulph.)

Magnesium Sulphate

Synonym—Epsom Salts.

Magnesium sulphate may be obtained by the action of sulphuric acid on magnesium carbonate, the latter being usually in the form of magnesite, a widely-distributed native basic carbonate. Large quantities are also obtained from the mineral, kieserite, $\text{MgSO}_4\cdot \text{H}_2\text{O}$, which is found in the Stassfurt deposits and is almost insoluble in water, but is gradually converted into the heptahydrate by prolonged contact with water. Magnesium sulphate occurs in colourless, odourless crystals, with a cool, saline, bitter taste and a neutral reaction. It effloresces in warm, dry air, and on heating at 150° to 160° is converted into the monohydrate; the last molecule of water of crystallisation is expelled at about 280° .

Soluble in water (1 in 1.5) and boiling water (20 in 3); almost insoluble in alcohol (90 per cent.).

Standard, B.P.—Magnesium sulphate contains not less than 99.5 per cent. and not more than the equivalent of 102 per cent. of $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$. Arsenic limit, 2 parts per million. Lead limit, 5 parts per million. The aqueous solution is neutral to litmus. It complies also with limit tests for zinc, chloride and iron.

Action and Uses.—Magnesium sulphate is a saline purgative. When taken by the mouth, it exerts a hydragogue cathartic action, which is entirely due to the property common to hypertonic non-absorbable solutions of withdrawing fluid by osmosis from the surrounding tissues. The Mg ion is only sparingly absorbed, and the SO_4 ion also is almost entirely excreted by the rectum; magnesium sulphate is therefore one of the most powerful of the saline purgatives, its positive and negative ions both contributing to this result. It produces no irritation; the increased peristalsis results from distention due to the presence of an increased quantity of fluid. Nevertheless, injections of magnesium sulphate under the skin, in about 50 per cent. of cases, produce some action on the bowels, probably from the direct irritation of the drug during excretion by the gut. Concentrated solutions are taken in dropsy, and in inflammatory and congestive conditions, to remove fluid and reduce blood pressure. In cholecystitis and some cases of catarrhal jaundice, 50 millilitres of a 25 per cent w/v solution administered directly into the duodenum by means of a duodenal tube, or given orally on a fasting stomach, is used to promote evacuation of the gall bladder. In tropical dysentery good results are obtained by giving 4 grammes (1 drachm) of magnesium sulphate with a few minims of dilute sulphuric acid, in concentrated solution, every two hours. With ferrous sulphate it is given in anæmia, usually with the addition of dilute sulphuric acid. It is the most commonly used domestic saline purgative in chronic constipation, and forms one of the chief ingredients of aperient mineral waters. It is used in baths as a fat-reducing agent, and for the treatment of rheumatism and lumbago.

Magnesium sulphate is a general protoplasmic poison and readily paralyses nerve structures. A 25 per cent. w/v solution of magnesium sulphate, injected into the spinal canal in doses of from 2.5 to 6 millilitres (40 to 90 minims), has given good results in tetanus. It should be employed at as early a stage as possible; in desperate cases, intra-cerebral injections have been used. Such injections have a paralytic action; they relax the muscles and prevent spasm. Intravenously, 10 to 25 millilitres (150 to 375 minims) of a 10 per cent. w/v solution has been found useful to control the convulsions in eclampsia. Magnesium sulphate used with morphine prolongs and intensifies the analgesic action of the latter. Hypodermic injections of 3 millilitres (45 minims) of isotonic solution (7.3 per cent. w/v) have been given in chorea. Applied locally, solutions of magnesium sulphate have an

anæsthetic action; a saturated solution has been used in orchitis, arthritis and other painful inflammations. Carbuncles, boils, etc., are well treated with wet dressings of a 25 per cent. w/v solution; this method has, however, been superseded generally by the use of magnesium sulphate paste (see *Magnesii Sulphas Exsiccatus*).

Magnesium sulphate is usually **administered** in solution or as *Magnesii Sulphas Effervescens*; it should be taken well diluted on an empty stomach. *Mistura Alba* is a popular form of administration. Dilute solutions are given in cases of lead poisoning to form the relatively insoluble lead sulphate, but it should be remembered that lead sulphate may produce lead poisoning. Solutions of magnesium sulphate for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. Magnesium sulphate is **incompatible** with alkali carbonates and bicarbonates. Strong solutions are incompatible with potassium and ammonium bromides, the double sulphate crystallising out. Cases of **poisoning** by magnesium sulphate have been reported. Hourly doses of mercurous chloride, 0.03 gramme ($\frac{1}{2}$ grain), are recommended, and large intravenous injections of normal saline solution, but the most valuable treatment is the injection of a 5 per cent. solution of a calcium salt which, in sufficient amount, completely counteracts the poisonous action of magnesium.

Dose.—2 to 16 grammes ($\frac{1}{2}$ to 4 drachms).

Preparations

Magnesii Sulphas Effervescens, B.P.C.—(*Mag. Sulph. Efferv.*)—Effervescent Magnesium Sulphate. *Syn.*—Effervescent Epsom Salts. About 1 in 2 of the crystalline salt. **Dose.**—For repeated administration, 4 to 12 grammes (1 to 3 drachms). For a single administration 16 to 30 grammes ($\frac{1}{2}$ to 1 ounce).

Effervescent magnesium sulphate, prepared from an equivalent quantity (500 grammes) of crystalline magnesium sulphate, was included in the British Pharmacopœia, 1914.

Mistura Alba, B.P.C.—(*Mist. Alb.*)—White Mixture. Each fluid ounce contains 120 grains of magnesium sulphate and 20 grains of light magnesium carbonate, in peppermint water. **Dose.**—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Mistura Sennæ Composita, B.P.—(*Mist. Senn. Co.*)—Compound Mixture of Senna. *Syn.*—Black Draught. Magnesium sulphate, 25 per cent. w/v, with liquid extract of liquorice, compound tincture of cardamom and aromatic spirit of ammonia, in infusion of senna. **Dose.**—30 to 60 millilitres (1 to 2 fluid ounces).

MAGNESII SULPHAS EXSICCATUS

(*Mag. Sulph. Exsicc.*)

Exsiccated Magnesium Sulphate

Synonym—Dried Epsom Salts.

Exsiccated magnesium sulphate may be prepared by drying magnesium sulphate at 100° until it has lost approximately 25 per cent.

of its weight. It occurs as a white powder. It should be stored in well-stoppered bottles.

Soluble in water (1 in 2); more rapidly soluble in hot water.

Standard.—Exsiccated magnesium sulphate, determined by the method of the British Pharmacopœia for Magnesii Sulphas, contains not less than 62 per cent and not more than 70 per cent of MgSO_4 ; each gramme of the residue is equivalent to 1.081 grammes of MgSO_4 . Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. 7.5 grammes dissolves in 20 millilitres of water, forming a solution which may be slightly turbid at first, but clears in a few minutes (limit of insoluble matter).

Action and Uses.—The medicinal properties of exsiccated magnesium sulphate are virtually those of magnesium sulphate. Its uses are, however, confined to certain preparations where it would be disadvantageous to use the ordinary salt. Exsiccated magnesium sulphate is one of the chief ingredients of effervescent and non-effervescent aperient powders or granules. Pasta Magnesii Sulphatis is used extensively as an application for carbuncles, boils, etc. The inflamed area is covered over with the paste spread on lint, jaconet is applied over the lint and, finally, cotton wool over and around the parts, the dressing being renewed until the central slough has separated, leaving a healthy, granulating surface.

Dose.—2 to 12 grammes ($\frac{1}{2}$ to 3 drachms).

Preparations

Pasta Magnesii Sulphatis, B.P.C.—(Past. Mag. Sulph.)—Magnesium Sulphate Paste. *Syn.*—Morison's Paste. Exsiccated magnesium sulphate dried at 100° , 45 per cent., and glycerin, with 0.5 per cent. of phenol.

Sal Aperiens Sulphuratum, B.P.C.—(Sal. Aper. Sulphur.)—Sulphurated Aperient Salt. *Syn.*—Harrogate Salts. Sulphurated potash, 3 per cent., and potassium acid tartrate, 15 per cent., with exsiccated magnesium sulphate. **Dose.**—4 to 8 grammes (1 to 2 drachms).

MALTOSUM

(Maltos.)

Maltose

Maltose is the β -maltose obtained from starch by the hydrolytic action of the enzyme diastase. It may be prepared by the action of malt extract on starch paste, and purified from dextrins by mixing the thin syrup obtained after evaporation with alcohol. The dextrin is removed by filtration, and the maltose obtained from the filtrate by evaporation and crystallisation. It crystallises from water in plates with one molecule of water, and from alcohol in crusts in the anhydrous

state. It reduces Fehling's solution, and may be distinguished from dextrose by not-reducing a solution of copper acetate in 1 per cent. acetic acid, and from lactose by the appearance of its osazone. It is dextrorotatory. On hydrolysis with mineral acids it yields dextrose.

Crystalline β -maltose, having the following properties, is used as a constituent of culture media:—Melting-point, 160° to 165° ; specific rotation, in 2 per cent. aqueous solution, $+129.0^{\circ}$ to $+129.3^{\circ}$; 1 gramme dissolves in 50 millilitres of alcohol (95 per cent.) without residue (limit of dextrin), and its osazone has a melting-point not lower than 205° .

Soluble in water and alcohol

Action and Uses.—It is used largely in bacteriological culture media. The use of carbohydrate mixtures containing maltose and dextrans for infant-feeding is described under *Lactosum*.

MANGANI CHLORIDUM

(Mang. Chlorid.)

Manganese Chloride

Manganese chloride may be prepared by dissolving manganese carbonate in hydrochloric acid, filtering the solution, concentrating, and allowing to crystallise. It occurs in the form of tabular crystals or as a granular, very hygroscopic powder, having a pale rose-red colour, and a bitter, sharp, styptic, afterwards saline taste. The diluted aqueous solutions are almost colourless, concentrated solutions pale red, and alcoholic solutions greenish. The latter burns with a red flame. The salt loses all its water of crystallisation at 100° . The anhydrous salt dissolves in water, with evolution of heat, melts in the absence of air at a red heat, and sublimes at a higher temperature. Heated in contact with air, it loses hydrochloric acid and yields an oxychloride.

Soluble in water (about 1 in 1) and alcohol; insoluble in ether.

Action and Uses.—Manganese chloride has the general properties of manganese salts, which are said to be more powerful stimulants to antibody formation than salts of other metals. Injected into experimental animals immunised against certain bacterial infections, they are said to increase very considerably the amount of antitoxin in the blood. Manganese salts are used in the treatment of staphylococcal infections, such as boils, furunculosis, etc. Manganese chloride, given by hypodermic injection, has been used in the treatment of pulmonary tuberculosis, in doses of 2.5 to 5 millilitres (40 to 75 minims) of a 0.6 per cent. w/v solution, given at intervals of three to five days. In dementia præcox, successful results have been reported from a course

of 30 twice-weekly injections of a 0.4 per cent. w/v solution, commencing with 2 millilitres (30 minims) and increasing to 8 millilitres (120 minims). This course is followed by oral doses of 0.3 gramme (5 grains) twice daily for one month. Small doses of manganese salts are sometimes given with iron in syrups and pills for the treatment of microcytic anæmia. As a local application, manganese chloride has been used to stimulate syphilitic and other indolent ulcers. Solutions of manganese chloride for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration.

Dose.—0.3 gramme (5 grains); 0.016 to 0.03 gramme ($\frac{1}{4}$ to $\frac{1}{2}$ grain), by injection.

MANGANI BUTYRAS.—Manganese butyrate, $(C_3H_7\text{-COO})_2Mn$, is used in 1 per cent. w/v solution as a remedy for furunculosis and for staphylococcal and gonococcal infections. Intramuscular injections of 1 to 2 millilitres (15 to 30 minims) of the solution may be made at intervals of 5 days, with a maximum number of three injections. Solutions of manganese butyrate for injection may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. They should be stored protected from light.

MANGANI SULPHAS.—Manganese sulphate, $MnSO_4 \cdot 4H_2O$, occurs in colourless or pale rose-coloured crystals, or as a nearly white powder, with a slightly bitter and astringent taste. It is soluble in water (1 in 1.5), the solution being neutral or very slightly acid to litmus, and insoluble in alcohol.

Preparation

Liquor Ferri Peptonatis cum Mangano, B.P.C.—(Liq. Ferr. Pepton. c. Mang.)—Solution of Iron Peptonate with Manganese. *Syn.*—Solution of Peptonised Iron with Manganese. Each fluid drachm contains about $\frac{1}{2}$ grain of manganese chloride with solution of iron peptonate. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

MANGANI DIOXIDUM PRÆCIPITATUM

(Mang. Diox. Præcip.)

Precipitated Manganese Dioxide

Synonym—Mangani Peroxidum Præcipitatum

Precipitated manganese dioxide consists chiefly of manganese dioxide, with small amounts of other oxides of manganese. It may be prepared by dissolving 5 parts of manganese sulphate in 100 parts of distilled water, diluting 25 parts of solution of ammonia and 25 parts of solution of hydrogen peroxide, each with an equal volume of distilled water, mixing, pouring the mixed solutions slowly, with constant stirring, into the solution of manganese sulphate, and allowing to stand for one hour, stirring frequently. The precipitate is washed and dried. It occurs as a very fine, heavy, odourless, tasteless, black powder, free from grittiness. Manganese dioxide is found in nature chiefly

in the form of pyrolusite, as steel-grey, prismatic crystals, having a specific gravity of 4.9, and also in the amorphous form, psilomelane, in which form it contains more or less iron oxide, calcium carbonate and earthy matter

Insoluble in water and alcohol; soluble in hot mineral acids, entirely soluble in cold hydrochloric acid.

Standard.—Precipitated manganese dioxide contains not less than 80 per cent. of MnO_2 . 1 gramme, digested with a mixture of 2 grammes of oxalic acid, 20 millilitres of distilled water and 3 millilitres of sulphuric acid for several hours on a water-bath, leaves not more than 0.2 per cent. of insoluble residue (limit of insoluble substances).

Assay.—Heat about 0.15 gramme, accurately weighed, with 50 millilitres of N/10 oxalic acid and 3 millilitres of sulphuric acid to 80° , and titrate with N/10 potassium permanganate; each millilitre of N/10 oxalic acid is equivalent to 0.004347 gramme of MnO_2 .

Action and Uses.—Precipitated manganese dioxide has been used in conjunction with iron salts in the treatment of anæmia. It may be **administered** in cachets or in pills.

Dose.—0.12 to 0.5 gramme (2 to 8 grains)

MANGANI GLYCEROPHOSPHAS

(Mang. Glycerophosph.)

Manganese Glycerophosphate

Synonym—Manganese Glycerylphosphate

Manganese glycerophosphate, $\text{MnC}_3\text{H}_5(\text{OH})_2\text{PO}_4$, may be prepared by neutralising glycerophosphoric acid with manganese carbonate. It occurs as a pale pink, amorphous powder.

Soluble in water

Standard.—Manganese glycerophosphate contains not less than 97 per cent. of $\text{C}_3\text{H}_7\text{O}_6\text{PMn}$, calculated on the substance dried at 130° . Loss on drying at 130° , not more than 5 per cent. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. 0.25 gramme complies with the limit test for iron. Dissolve 0.5 gramme in 10 millilitres of water acidified with sulphuric acid, add 2 millilitres of mercuric sulphate solution, boil and, if necessary, filter while hot; the hot filtrate, on the addition of potassium permanganate solution drop by drop, does not produce a white precipitate (limit of citrate). When shaken with 25 parts of dehydrated alcohol and filtered, it yields on evaporation of the alcohol, and subsequent drying at 70° for one hour, not more than 1 per cent. of residue (limit of glycerin, etc.). A weight of the substance equivalent to 1 gramme dried at 130° , dissolved in 100 millilitres of water, requires for neutralisation to phenolphthalein

not more than 2 millilitres of N/10 hydrochloric acid or of N/10 sodium hydroxide (limit of alkalinity or acidity). The neutralised solution requires not less than 8.0 millilitres of N/2 hydrochloric acid for neutralisation to methyl orange (minimum limit of glycerophosphate). 1 gramme dissolves in 100 millilitres of water, with only a slight turbidity.

Assay.—Ignite about 0.5 gramme, accurately weighed, and weigh the residue; 1 gramme of the residue is equivalent to 1.585 grammes of $C_3H_7O_8PMn$.

Action and Uses.—Manganese glycerophosphate has the general properties of manganese salts and the glycerophosphates. Like other manganese salts, it is sometimes used as a hæmatinic in conjunction with salts of iron. It may be **administered** in pills, tablets, or cachets

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

MANGANI HYPOPHOSPHIS

(Mang. Hypophosph.)

Manganese Hypophosphite

Manganese hypophosphite may be prepared by dissolving manganese carbonate in the equivalent quantity of hypophosphorous acid and crystallising from the hot aqueous solution, or by boiling a solution of barium hypophosphite with a solution of manganese sulphate, filtering, and evaporating or allowing to crystallise. Manganese hypophosphite occurs in white or slightly rose-coloured, odourless, nearly tasteless crystals, or as a granular powder. The aqueous solution is acid to litmus. On heating, the salt swells, evolves spontaneously inflammable hydrogen phosphide, and leaves a residue of manganese pyrophosphate. It is readily oxidised by nitric acid, and reduces acidified mercuric chloride solution to metallic mercury.

Soluble in water (1 in 7) and boiling water (1 in 6); almost insoluble in alcohol.

Standard.—Manganese hypophosphite, determined by the method for Calc. Hypophosphis, contains not less than 97 per cent of $Mn(H_2PO_2)_2 \cdot H_2O$; each millilitre of N/10 iodine is equivalent to 0.005075 gramme of $Mn(H_2PO_2)_2 \cdot H_2O$. Arsenic limit, 10 parts per million. Lead limit, 50 parts per million. 1 gramme, dissolved in 20 millilitres of water and filtered, remains clear on the addition of an equal volume of calcium sulphate solution (limit of barium).

Action and Uses.—Manganese hypophosphite has the general properties of manganese salts and the hypophosphites. Like other

manganese salts, it is sometimes used as a hæmatinic in conjunction with salts of iron. It may be **administered** in pills, tablets, or cachets, or in compound syrups and other preparations. Syrupus Hypophosphitum Compositus contains in 8 millilitres (2 fluid drachms) 0·037 gramme ($\frac{1}{2}$ grain) of manganese hypophosphite.

Dose.—0·06 to 0·3 gramme (1 to 5 grains).

MANNA

(Manna)

Manna

Manna is the dried, saccharine juice exuded from the stems of *Fraxinus Ornus* Linn. (Fam. Oleaceæ), a small tree indigenous to the Eastern Mediterranean, and cultivated in Sicily. When the trees are about ten years old, during July and August a vertical series of oblique incisions is made in the bark to the depth of the cambium; a juice slowly exudes from the wounds, and either dries on the stem (flake manna), or, in wet seasons, drops from the stems and is caught upon tiles, or the flattened cladodes of cactus, yielding a quality inferior to the flake manna.

Flake manna occurs in yellowish-white, brittle, stalactitic masses, about 10 to 15 centimetres long and 2 to 2·5 centimetres wide, which are more or less triangular in section, smooth and slightly concave on the side which was adherent to the tree; the structure is indistinctly crystalline. The odour is slight and agreeable, and the taste is sweet. The inferior qualities consist of fragments agglutinated together, often darker in colour. The cold-water extract does not undergo vinous fermentation with yeast.

Manna **contains** the hexahydric alcohol, mannitol, of which it may contain from about 40 to 60 per cent. Other constituents are mannotetrose (stachyose, about 12 to 16 per cent.), mannotriose (about 6 to 16 per cent.), dextrose, mucilage, water (about 10 per cent.) and traces of a fluorescent substance (fraxin). Mannitol can be isolated from manna by extraction with hot alcohol, cooling, and recrystallising the crystals that separate; it is soluble in about 6·5 parts of water, easily soluble in hot alcohol, sparingly in cold. Mannotetrose is dextrorotatory, and each molecule yields on hydrolysis two molecules of galactose and one each of dextrose and lævulose; each molecule of mannotriose yields two molecules of galactose and one of dextrose.

Action and Uses.—Manna is used as a gentle laxative for infants and children. It is sometimes administered in the form of syrup (Syrupus Mannæ, 1 in 10; dose, 1 to 4 fluid drachms), and as a compound syrup containing manna, senna and fennel.

Dose.—2 to 16 grammes ($\frac{1}{2}$ to 4 drachms).

MARANTA

(Marant.)

Arrowroot

Arrowroot is the starch prepared from the rhizomes of *Maranta arundinacea* Linn. (Fam. Marantaceæ), a native of Central America, but cultivated in the West Indies, Natal and other tropical and sub-tropical countries.

Arrowroot is a white powder, much of which adheres to form small, irregular masses up to about 5 millimetres in maximum length, and crepitates slightly when pressed. It is tasteless and odourless.

The diagnostic **microscopical** characters of arrowroot are the ovoid to ellipsoid shape of the granules, which frequently show small, local enlargements or tuberosities; the well-marked hilum, generally situated near the broader end of the granules, and frequently taking the form of a two-rayed cleft, which resembles the appearance of the wings of a bird in flight; the clearly marked, but very fine, concentric striations. The granules are simple, and vary in size from about 7 to 75 microns in their greatest dimension, being most commonly from 30 to 50 microns; they exhibit a well-marked cross by polarised light, and show brilliant colours with a selenite plate.

Arrowroot **contains** about 14 to 17 per cent. of moisture, the remainder of the granule consisting of 66 per cent. of polymerised amylose and 33 per cent. of amylopectin.

Varieties.—Several varieties of arrowroot are found in commerce and bear the names of their places of origin, e.g., Bermuda, St. Vincent, Natal, West Indian, etc.; the most highly valued variety is that from Bermuda. These varieties differ slightly in gelatinising properties.

Substitutes.—Many starches have been described as arrowroots and are sometimes substituted for arrowroot; the most important of these substitutes are the starches of potato, *Solanum tuberosum* Linn., sometimes known as English arrowroot, the sweet potato, *Ipomoea Batatas* Poir., sometimes known as Brazilian arrowroot, and various species of *Curcuma*, such as *C. angustifolia* Roxb. and *C. leucorhiza* Roxb., known as East Indian arrowroot. Potato starch is distinguished by the larger size, up to 100 or 150 microns, of many of its granules, which are sometimes compound, with 2 to 3 components, and have coarser striations, while the hilum has the form of a point situated usually at the narrower end of the ovoid granule. The granules of sweet potato starch are rounded, polyhedral or muller-shaped, many compound grains are present with 2 or 3 or sometimes up to 6 components; the individual granules are somewhat smaller than those of arrowroot, attaining a maximum of about 55 microns; the hilum is usually fissured or stellate and may be central or $\frac{1}{2}$ to $\frac{3}{4}$ eccentric. The granules of curcuma starch are typically scitamineous, about 30 to 60 or up to 140 microns long, 25 to 35 microns wide and 7 to 8 microns thick. The starch of *Manihot utilisima* Pohl is known as Brazilian, Bahia, Rio or Pará arrowroot. The granules are mostly compound, with 2 or 3 or up to 8 components which usually separate in the commercial starch. The simple granules are mostly sub-spherical and the components of compound grains are usually muller-shaped; the simple grains and smaller components measure 5 to 15 or 25 microns and the larger components 25 to 35 microns.

Standard.—Arrowroot loses, on drying at 100°, not more than 20 per cent. of its weight. Ash, not more than 0.3 per cent.

Action and Uses.—Arrowroot has the general properties of starch. It is used as a gruel in the treatment of diarrhœa. As a suspending agent it is used for preparing barium meals, and it is sometimes preferred for use in tablet-making, since it permits more rapid disintegration.

MARRUBIUM

(Marrub.)

Horehound

Synonyms.—Hoarhound; White Horehound.

Horehound consists of the dried leaves and flowering tops of *Marrubium vulgare* Linn. (Fam. Labiatae), an erect, herbaceous plant indigenous to Britain, and widely distributed over Europe.

The stem is quadrangular and branching; the leaves are cordate-ovate, shortly stalked and crenate, reticulate on both sides, and about 3 to 5 centimetres long. The stem and under surface of the leaves are covered with soft, woolly, whitish hairs. The flowers are small and white, in axillary verticillasters. The calyx has ten veins and ten teeth ending in rigid, hooked and recurved points; the corolla is bilabiate, the upper lip being small, erect and bilobed, and the lower lip trilobed. The drug has an agreeable odour, and a somewhat aromatic, bitter taste.

Horehound **contains** a crystalline bitter lactone, marrubiin, together with a little volatile oil and tannin. When infused with hot water for fifteen minutes, it yields about 20 per cent. of extractive. Marrubiin crystallises in colourless plates or needles, melting at about 160°; it is almost insoluble in water, but soluble in alcohol and ether.

Standard.—Horehound contains not more than 1 per cent. of foreign organic matter. Acid-insoluble ash, not more than 2 per cent.

Horehound, in powder (Pulvis Marrubii : Pulv. Marrub.), contains the constituents of Marrubium, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Horehound is expectorant and, in large doses, laxative. In the form of infusion, oxymel or syrup, it is a popular domestic remedy for coughs, colds and pulmonary affections.

Dose.—1 to 2 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ drachm).

Preparations

Infusum Marrubii Concentratum, B.P.C.—(Inf. Marrub. Conc.)—Concentrated Infusion of Horehound. About 1 in 2 $\frac{1}{2}$. When infusion of horehound or Infusum Marrubii is prescribed, this concentrated infusion diluted with seven times its volume of distilled water may be dispensed. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Syrupus Marrubii, B.P.C.—(Syr. Marrub.)—Syrup of Horehound. About 1 in 2. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

MASTICHE

(Mastich.)

Mastic

Mastic is a resinous exudation from *Pistacia Lentiscus* Linn. (Fam. Anacardiaceæ), a small tree indigenous to the Mediterranean countries. It is collected on the island of Chios (Scio) in the Ægean Sea, by puncturing the bark of the trees and allowing the oleo-resin, which is contained in schizogenous ducts in the bast, to exude and harden.

Mastic occurs in small, hard, globular or pyriform pieces, about 4 to 8 millimetres in diameter, or more rarely in ovoid or nearly cylindrical pieces up to 2 centimetres long and 1 centimetre wide. When fresh, the tears are pale yellow in colour, clear and glassy, but, on keeping, the surface becomes dull and dusty; they are brittle, and break with a conchoidal fracture. The acid number of mastic varies from about 50 to 67; specific gravity, 1.074; melting-point, about 106°. It is insoluble in water, partially soluble in alcohol or oil of turpentine, very soluble in chloroform (2 in 1), and in ether (2 in 1). The drug has a somewhat aromatic odour and agreeable taste, and breaks up, when chewed, into sandy fragments which agglomerate into a plastic mass.

Mastic **contains** resin, which is associated with about 2 per cent. of volatile oil. The resin has been separated into the following constituents: α - and β -masticinic acids (together forming about 4 per cent. of the drug), masticolic acid, α - and β -masticonic acids (about 38 per cent.), α -masticoresene (soluble in alcohol, about 30 per cent.), β -masticoresene (also called masticin, insoluble in alcohol, about 20 per cent.). The volatile oil consists chiefly of *d*-pinene.

Substitute.—East Indian or Bombay mastic is obtained from *P. Khinjuk* Stocks (and possibly other species); it somewhat resembles genuine mastic, but the tears are darker, less vitreous, and not so clean. It is also more soluble in alcohol, less soluble in oil of turpentine, and less disposed to agglomerate when chewed; the acid number varies from 103 to 109.

Action and Uses.—Mastic is used in Eastern countries as a masticatory to sweeten the breath and preserve the teeth and gums. It was formerly employed internally, as a stimulant to the mucous membranes in place of other terebinthinate resins, but is now rarely used. Solutions of mastic in alcohol, ether, or chloroform are used, applied on cotton wool, as temporary fillings for carious teeth. A surgical varnish containing mastic, 40 parts, castor oil, 1.2 parts, and benzene, to 100 parts, is used as a protective covering for wounds and to hold gauze and radium needles in position.

Dose. 1 to 3 grammes ($\frac{1}{4}$ to $\frac{3}{4}$ drachm).

Preparation

Tinctura Ammonia Composita, B.P.C.—(Tinct. Ammon. Co.)—Compound Tincture of Ammonia. *Syn.*—Eau de Luce. Mastic, 1 in 80, with alcohol (90 per cent.) and oil of lavender, in strong solution of ammonia.

MATICA

(Matic.)

Matico*Synonyms*—Matico Leaves; Maticæ Folia.

Matico consists of the dried leaves of *Piper angustifolium* Ruiz et Pav. (Fam. Piperaceæ), a shrub indigenous to Bolivia, Peru, Brazil and Colombia.

The leaves are from about 10 to 20 centimetres long and about 2 to 4 centimetres broad, lanceolate, acuminate, shortly petiolate, greyish or yellowish-green, and brittle; the base is cordate and unequal. The upper surface is tessellated by the depressed veinlets, dividing it into squares about 1 to 2 millimetres wide; the under surface has raised veinlets, the depressions thus formed being clothed with a coarse pubescence. Lateral veins curve rapidly towards the apex, being almost concurrent near the margin, which is entire and revolute. Flowering and fruiting spikes, when present, are slender, and about 10 to 15 centimetres long; the stalks have swollen nodes. The odour is slight and aromatic, and the taste bitter and camphoraceous.

The diagnostic **microscopical** characters are the numerous long, uniseriate covering hairs on both surfaces; the single row of hypodermis on the upper side; the dorsiventral mesophyll; the palisade tissue, usually two cells deep, with numerous large, sub-spherical idioblasts containing oil; the meristele of the midrib, consisting of about 4 to 10 vascular bundles in a crescent-shaped group; the scattered sclerenchymatous cells in the parenchyma of the midrib; the presence of acicular raphides and small prisms of calcium oxalate, and of spherical pollen grains about 25 to 30 microns in diameter.

Matico **contains** 1 to 3.5 per cent. of volatile oil, tannin, a bitter principle, and crystalline artanthic acid.

Substitutes.—The leaves of *Piper aduncum* Linn., often present in commercial matico, are distinguished by their more prominent, ascending, parallel veins, the spaces between which are nearly glabrous. Leaves of other species, such as *P. lineatum* Ruiz et Pav., *P. camphoriferum* C. DC. and *P. acutifolium* var. *subverhascifolium* Ruiz et Pav., yield volatile oils which differ from that of the genuine drug.

Standard.—Matico contains not more than 5 per cent. of the stems, flower spikes and other foreign organic matter. Acid-insoluble ash, not more than 6 per cent.

Action and Uses.—Matico has been employed as a styptic, but is now rarely used in medicine. The infusion (1 in 20) and tincture (1 in 5) have been used internally in mixture form; the latter is the more powerful styptic.

Dose.—2 to 8 grammes ($\frac{1}{2}$ to 2 drachms).

MATRICARIA

(Matric.)

Matricaria*Synonyms*—Chamomilla; German Chamomile.

Matricaria consists of the dried flowerheads of *Matricaria Chamomilla* Linn. (Fam. Compositæ), an annual plant indigenous to Northern Europe.

The dried flowerheads are about 6 millimetres in diameter, exclusive of pistillate ray florets, which have usually fallen off; these are about 12 to 20 in number, and are white at first, but darken with age; each ligulate corolla is about 6 millimetres long and 2 millimetres wide, and shows four veins and usually three teeth. The numerous brownish-yellow, tubular, disc florets, which are about 2 millimetres long, are usually firmly attached to a conical, hollow receptacle, which is about 5 millimetres high, bears no paleæ, and is surrounded by an involucre of about two to three rows of small imbricated bracts, having blunt apices and scarious margins. There is no pappus. The drug has a pleasant aromatic odour and a bitter taste.

Matricaria **contains** a blue volatile oil (German chamomile oil), a thick fluid, which is freely soluble in alcohol. It differs somewhat from oil of chamomile, but its exact composition has not been determined. In addition to the volatile oil, matricaria contains salicylic acid, apigenin, a glycoside of apigenin, umbelliferone methyl-ether, choline, triacontane, a phytosterol and a mixture of fatty acids. Matricaria yields to alcohol (60 per cent.) about 20 per cent. of extractive. The ash is about 10 per cent.

Standard.—Matricaria contains not more than 8 per cent. of its stems and other foreign organic matter. Acid-insoluble ash, not more than 4 per cent.

Matricaria, in powder (Pulvis Matricariæ; Pulv. Matric.), contains the constituents of Matricaria, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Matricaria has similar properties to chamomile, and is used for similar purposes.

Dose.—8 to 16 grammes (2 to 4 drachms).

MEDULLA RUBRA

(Medull. Rub.)

Red Bone Marrow

Red bone marrow is the mixed fatty material from the bones of calves and young oxen. The bones from recently killed animals are sawn longitudinally by machine saws, and the marrow is extracted.

It is the highly vascular connective tissue which occupies the spaces in the spongy, or cancellous, tissue. Marrow obtained from calves occurs as a reddish mass containing some fat cells and a large number of amœboid marrow cells, which are the precursors of the leucocytes found in the blood. Amongst the cells, a variable number of erythroblasts, which are the nucleated red cells, are to be found; from these cells the hæmoglobin-containing corpuscles of the blood are developed. The yellow marrow found in the bones of old animals contains no erythroblasts, and is not used in preparations for medical treatment.

Action and Uses.—Red bone marrow has been employed in the treatment of the anæmias, with a view to increasing the hæmoglobin content of the blood by stimulating the red bone marrow, but its use in pernicious anæmia is almost entirely superseded by preparations of liver or hog stomach. It is **administered** in the fresh state, or in the form of *Extractum Medullæ Rubræ*.

Dose.—1·3 to 2·6 grammes (20 to 40 grains).

Preparations

Extractum Malti Liquidum et Medullæ Rubræ, B.P.C.—(*Ext. Malt. Liq. et Medull. Rub.*)—Liquid Extract of Malt and Red Bone Marrow. Liquid extract of malt and extract of red bone marrow, equal parts. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Extractum Medullæ Rubræ, B.P.C.—(*Ext. Medull. Rub.*)—Extract of Red Bone Marrow. *Syn.*—Glycerin Extract of Red Bone Marrow. 1 in 4. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Glycerinum Glycerophosphatum cum Medulla Rubra, B.P.C.—(*Glycer. Glycerophosph. c. Medull. Rub.*)—Glycerin of Glycerophosphates with Red Bone Marrow. *Syn.*—Elixir Glycerophosphatum cum Medulla Rubra; Elixir of Glycerophosphates with Red Bone Marrow; Glycerol Glycerophosphatis cum Medulla Rubra. Equal parts of extract of red bone marrow and compound glycerin of glycerophosphates. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Syrupus Glycerophosphatum Compositus cum Medulla Rubra, B.P.C.—(*Syr. Glycerophosph. Co. c. Medull. Rub.*)—Compound Syrup of Glycerophosphates with Red Bone Marrow. Compound syrup of glycerophosphates and extract of red bone marrow, equal parts. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

MEL DEPURATUM

(*Mel Depur.*)

Purified Honey

Synonyms—Clarified Honey; Mel Despumatum.

Purified honey is prepared by melting honey, allowing it to stand, straining off the impurities which rise to the surface, and adjusting to a specific gravity of 1·36 by the addition of distilled water. Honey is a saccharine secretion deposited in the honeycomb by the bee, *Apis mellifica* Linn. (Order Hymenoptera) and other species, the saccharine

matter being extracted from the nectaries of flowers by the bee, the salivary glands of which contain the enzyme *invertase* which converts sucrose into invert sugar. Honey occurs as a viscous, translucent, syrupy liquid, or as a soft, opaque, crystalline, semi-solid mass, varying in colour from white to reddish-brown. Purified honey occurs as a thick, syrupy, translucent, pale yellow or yellowish-brown liquid, with a characteristic odour and a sweet, characteristic taste.

Honey **contains** about 70 to 80 per cent. of dextrose and *lævulose*; other constituents are water, small quantities of sucrose, dextrin, wax, proteins, volatile oil and formic acid, while pollen and flocculent matter are usually also present in suspension, and tend to induce fermentation. The finest grade of honey is that which is allowed to drain from the comb, but most of the honey of commerce is obtained by submitting the honeycomb to pressure, with or without the application of heat, or by means of a centrifuge.

Standard, B.P.—Purified honey has a specific gravity of 1.359 to 1.361. Optical rotation of a 20 per cent. w/v solution, decolourised if necessary, from $+0.6^{\circ}$ to -2° , corresponding to a specific rotation of $+3^{\circ}$ to -10° for the original purified honey. Ash, not more than 0.3 per cent. w/w. It complies also with limit tests for chloride and sulphate and a test for absence of artificial invert sugar.

Action and Uses.—Purified honey is used as a demulcent and sweetening agent. It is employed in cough mixtures with expectorants and sedatives, and is a convenient vehicle for the application of borax to the mouth in aphthous conditions.

Dose.—2 to 8 grammes ($\frac{1}{2}$ to 2 drachms).

Preparations

Linctus Acidus, B.P.C.—(Linct. Acid.)—Acid Linctus. Oxymel, 1 in 3, with dilute sulphuric acid, emulsion of chloroform and treacle. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Mel Boracis, B.P.—(Mel. Borac.)—Honey of Borax. *Syn.*—Borax Honey; Borax and Honey. Borax, 10 per cent. w/w, dissolved in glycerin and purified honey.

Oxymel, B.P.—(Oxymel)—Oxymel. Acetic acid and distilled water, of each 15 per cent. v/v, in purified honey. Specific gravity, 1.258 to 1.263. Optical rotation at 20° of a 25 per cent. w/v solution in water, decolourised if necessary with charcoal, $+0.6^{\circ}$ to -1.9° . It complies also with a test for limits of acidity. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

MENTHA PIPERITA

(Menth. Pip.)

Peppermint

Peppermint consists of the dried leaves and flowering tops of *Mentha piperita* Linn. (Fam. Labiatæ), a plant growing wild throughout

Europe, and cultivated in England, France, Germany, Russia and America. There are two varieties, known respectively as black peppermint and white peppermint.

The stems are quadrangular, and purplish or greenish in colour, with scattered, deflexed hairs and petiolate, ovate-lanceolate, light or dark green leaves, 3 to 8 centimetres long and about half that width, acute and sharply serrate. The small purple flowers occur in terminal, obtuse spikes consisting of closely-arranged verticillasters; each flower has a five-toothed, tubular calyx, a four-lobed campanulate corolla, and four short, equal stamens. The odour is strong and characteristic and the taste pungent and cooling. The drug **contains** volatile oil.

Standard.—Peppermint contains not more than 2 per cent. of foreign organic matter. Acid-insoluble ash, not more than 2 per cent.

Action and Uses.—Peppermint is an aromatic stimulant and carminative, and is used chiefly in the form of its volatile oil.

Dose.—2 to 4 grammes ($\frac{1}{2}$ to 1 drachm).

MENTHA PULEGIUM.—Pulegium, or pennyroyal, consists of the dried leaves and flowering tops of *Mentha Pulegium* Linn., a plant indigenous to Britain and most parts of Europe. The herb is very much branched, and prostrate or erect, with bluntly quadrangular stems. The leaves are petiolate, ovate and from 6 to 20 millimetres long with an entire to crenate margin. The flowers are in distant, axillary, globose verticillasters; the calyx and pedicels are pubescent or hispid. The odour is strong and characteristic, and the taste pungent and mint-like. It contains volatile oil. Pulegium has similar properties to peppermint and is used as an antispasmodic, but it is somewhat more irritant to the genito-urinary tract during excretion, and may thus reflexly augment uterine movements; it is, therefore, also used as an emmenagogue. The volatile oil is chiefly employed. Dose.—2 to 4 grammes ($\frac{1}{2}$ to 1 drachm).

MENTHA VIRIDIS.—Spearmint, or mint, consists of the dried leaves and flowering tops of *Mentha viridis* Linn., a native of Europe and Asia. It is widely cultivated for culinary use and is usually met with in commerce finely rubbed. Spearmint has a square stem and sessile, elliptical-oblong, sharply serrate leaves, about four times as long as they are wide. The flowers are in slender, somewhat cylindrical terminal spikes and the stamens are rather long. The odour is strong and characteristic; the taste is somewhat bitter and pungent. The drug contains volatile oil. Spearmint resembles peppermint in its properties, but its flavour is less agreeable in medicines. Dose.—2 to 4 grammes ($\frac{1}{2}$ to 1 drachm).

Preparations

Aqua Menthae Piperitæ Concentrata, B.P.—(Aq. Menth. Pip. Conc.)—Concentrated Peppermint Water. Oil of peppermint, 1 in 50. One part added to 39 parts of distilled water yields a preparation which is approximately equivalent in strength to distilled peppermint water, but contains 1·5 per cent. v/v of alcohol (90 per cent.). Dose.—0·3 to 1 millilitre (5 to 15 minims).

This concentrated water, prepared with 3 per cent. of oil of peppermint, was included in the British Pharmaceutical Codex, 1923.

Aqua Menthae Piperitæ Destillata, B.P.—(Aq. Menth. Pip. Dest.)—Distilled Peppermint Water. Oil of peppermint, 1 in 1000. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Aqua Menthae Viridis Concentrata, B.P.C.—(Aq. Menth. Vir. Conc.)—Concentrated Spearmint Water. Oil of spearmint, 1 in 50. One part added to 39 parts of distilled water yields a preparation which is approximately equivalent in strength to distilled spearmint water, but contains 1·5 per cent. v/v of alcohol (90 per cent.). Dose.—0·3 to 1 millilitre (5 to 15 minims).

Aqua Menthæ Viridis Destillata, B.P.C.—(Aq. Menth. Vir. Dest.)—Distilled Spearmint Water. Oil of spearmint, 1 in 1000. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

This water was included in the British Pharmacopœia, 1914, under the name of Aqua Menthæ Viridis.

MENTHOL

(Menthol)

Menthol

Menthol, *l-p*-menthan-3-ol, $\text{CH}_3\cdot\text{C}_6\text{H}_9(\text{OH})\text{C}_3\text{H}_7$, is a saturated cyclic alcohol, which is obtained from the volatile oils of various species of *Mentha*, and is imported into England chiefly from Japan. It is obtained mainly from *M. arvensis* var. *piperascens* Holmes in Japan, var. *glabrata* Holmes in China and *M. piperita* Linn. in America, and is separated from the oils by freezing. Menthol occurs in colourless, acicular or prismatic crystals, with a penetrating odour similar to that of peppermint, and a warm, aromatic taste, followed by a sensation of coldness. It volatilises slowly at ordinary temperatures but rapidly on warming. Specific gravity, about 0.890; boiling-point, about 216° . The alcoholic solution is lævorotatory and neutral to litmus. When triturated with camphor, thymol and other substances, the mixture liquefies. It is readily identified by means of its benzoic ester which is obtained by heating menthol with benzoic anhydride; it has a melting-point of $54\cdot5^\circ$ and is almost non-volatile in steam. Menthol may be differentiated from thymol, or the presence of the latter in menthol detected, by the addition of 3 drops of sulphuric acid and 1 drop of nitric acid to 1 millilitre of a solution of menthol in glacial acetic acid; no green colouration should be produced. Synthetic menthol, having similar properties but with a melting-point of from 30 to 35° , is also available, and can be obtained in the form of colourless crystals. It is a mixture of stereo-isomerides.

Very **soluble** in alcohol (90 per cent.) (5 in 1), ether (8 in 3), chloroform (about 4 in 1), liquid paraffin (1 in 6), light petroleum (10 in 7), olive oil (1 in 4) and volatile oils; almost insoluble in water and glycerin.

Standard, B.P.—Menthol has a melting-point of 42° to 43° . Residue on volatilisation, not more than 0.05 per cent.

Action and Uses.—Menthol is an antiseptic with a mildly anæsthetic action. When applied to the skin, a sensation of cold is produced, with dilatation of the vessels and a rise in the skin temperature, followed by partial anæsthesia and a feeling of numbness. Menthol is employed occasionally as a carminative, but it is liable to upset digestion. A solution in oil, or a mixture with an inert substance, may be **administered** in capsules, or it may be given in pills massed with powdered soap. When prescribed in pills with camphor, phenol, chloral hydrate,

thymol, or other substance with which menthol liquefies, a small quantity of wax should be added. Pastilles containing menthol, frequently with oil of eucalyptus, are employed for nasal and bronchial catarrh.

Menthol is applied **externally**, in the form of cones, or as a liniment or ointment with methyl salicylate, as an analgesic in neuralgia and rheumatic affections. Menthol is much used as an inhalation or application to inflamed nasopharyngeal and laryngeal mucous membranes. Mixed with camphor and oil of eucalyptus, it is inhaled from cotton wool or from hot water for the relief of catarrh. It is a common ingredient of snuffs, and is used in solution in light liquid paraffin (1 or 2 per cent.) as a spray to the nose or larynx. Menthol ointment (1 per cent. in soft paraffin) is applied to the nares in coryza. Mixtures of equal weights of menthol and chloral hydrate or camphor are applied on cotton wool to carious teeth to allay pain. Vapour rubs are preparations of menthol with other volatile substances in a basis of soft paraffin, and are applied to the chest for their local action and on account of their value when inhaled.

Dose.—0·03 to 0·12 gramme ($\frac{1}{2}$ to 2 grains).

MENTHYLIS VALERIANAS.—Menthyl valerianate may be prepared by the esterification of menthol with valerianic acid. It occurs as a colourless, pleasantly smelling liquid, insoluble in water and miscible with alcohol, ether and fatty oils. It is used as a nerve sedative and as a remedy for sea-sickness.

Preparations

Aqua Mentholis, B.P.C.—(Aq. Menthol.)—Menthol Water. A saturated solution of menthol in water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Emplastrum Mentholis, B.P.C.—(Emp. Menthol.)—Plaster of Menthol. Menthol, 15 per cent., in yellow beeswax and colophony

Insufflatio Mentholis, B.P.C.—(Insuff. Menthol.)—Menthol Insufflation. *Syn.*—Insufflatio Mentholis Composita; Menthol Snuff. Menthol, 1 in 20, with ammonium chloride, boric acid and lycopodium.

Insufflatio Mentholis et Cocainæ, B.P.C.—(Insuff. Menthol. et Cocain.)—Menthol and Cocaine Insufflation. *Syn.*—Menthol and Cocaine Snuff. Menthol, 2·5 per cent., and cocaine hydrochloride, 0·14 per cent., with ammonium chloride, camphor and lycopodium.

Nebula Cocainæ Composita, B.P.C.—(Neb. Cocain Co.)—Compound Cocaine Spray. Cocaine, 0·5 per cent. w/v, in compound menthol and thymol spray.

Nebula Guaiacolis et Mentholis, B.P.C.—(Neb. Guaiacol. et Menthol.)—Guaiacol and Menthol Spray. Guaiacol, 2 per cent. w/v, and menthol, 4 per cent. w/v, in light liquid paraffin.

Nebula Iodi et Mentholis, B.P.C.—(Neb. Iod. et Menthol.)—Iodine and Menthol Spray. Iodine, 2 per cent. w/v, and menthol, 4 per cent. w/v, in light liquid paraffin.

Nebula Mentholis et Thymolis Composita, B.P.C.—(Neb. Menthol. et Thymol. Co.)—Compound Menthol and Thymol Spray. Menthol, camphor and phenol, of each 2 per cent. w/v, and thymol, 0·2 per cent. w/v, in light liquid paraffin.

Pastilli Mentholis et Cocainæ, B.P.C.—(Pastil. Menthol. et Cocain.)—Menthol and Cocaine Pastilles. Each pastille contains menthol, $\frac{1}{20}$ grain, and cocaine hydrochloride, $\frac{1}{40}$ grain.

Pastilli Mentholis et Eucalyptolis, B.P.C.—(Pastil. Menthol. et Eucalyp.)—Menthol and Eucalyptol Pastilles. Each pastille contains menthol, $\frac{1}{10}$ gram, and eucalyptol, $\frac{1}{2}$ minim.

Pigmentum Mentholis et Tolueni, B.P.C.—(Pig. Menthol. et Toluén.)—Menthol and Toluene Paint. *Syn.*—Löffler's Paint. Menthol, 10 per cent. w/v, with dehydrated alcohol, strong solution of ferric chloride and toluene.

Spiritus Mentholis, B.P.C.—(Sp. Menthol.)—Spirit of Menthol. Menthol, 1 in 20, in alcohol (90 per cent.).

Spiritus Mentholis Compositus, B.P.C.—(Sp. Menthol. Co.)—Compound Spirit of Menthol. Camphor, menthol, terebene and eucalyptol, of each 1 in 10, in alcohol (90 per cent.). Dose.—10 drops, by inhalation.

MERCUROCHROMUM

(Mercurochrom.)

Mercurochrome

Synonym—Mercurochrome, 220 Soluble.

Mercurochrome consists chiefly of the disodium salt of dibromohydroxymercury-fluorescein, $C_{20}H_4O_6Br_2Na_2Hg$, and may be prepared by the interaction of dibromofluorescein and mercuric acetate. It occurs as greenish, iridescent scales or granules, giving a dark red aqueous solution which, on dilution, shows a marked green fluorescence.

Readily **soluble** in water; almost insoluble in alcohol; insoluble in chloroform and ether.

Standard.—Mercurochrome contains not less than 25 per cent. and not more than 28 per cent. of Hg, and not less than 21 per cent. and not more than 23 per cent. of Br, both calculated on the substance dried in a vacuum at 50° over sulphuric acid. Loss on drying in a vacuum at 50° over sulphuric acid, not more than 10 per cent. Dissolve 2.5 grammes in 50 millilitres of water at 15° , and allow to stand for twenty-four hours; centrifuge, and wash the deposit with water until the washings are colourless; dissolve the residue in 2 millilitres of nitric acid, warm slightly, dilute to 25 millilitres, and titrate with N/10 ammonium thiocyanate, using ferric ammonium sulphate as indicator; not more than 1 millilitre of N/50 ammonium thiocyanate is required (limit of free mercury). Dissolve 0.1 gramme in 10 millilitres of water, add 1 millilitre of N/1 sulphuric acid, allow to stand for five minutes, and filter; to the filtrate add 1 millilitre of hydrogen sulphide solution: the solution shows not more than a slight darkening in colour (limit of soluble mercury salts). Residue on ignition with sulphuric acid, not more than 22 per cent. (limit of sodium).

When used for intravenous injection, it complies with the test for toxicity.

Assay.—For mercury. Dissolve about 0.5 gramme, accurately weighed, in 10 millilitres of water. Add 100 millilitres of alcohol

(95 per cent.), 10 millilitres of hydrochloric acid and 1 gramme of zinc powder, and set aside in a warm place so that a steady evolution of gas proceeds. After one hour add 10 millilitres of hydrochloric acid and 1 gramme of zinc powder, and repeat the addition after another hour. Decant the solution through a filter and wash the residual amalgam twice with 10 millilitres of alcohol (95 per cent.) and then with water until free from chloride. Dissolve the residual amalgam, together with any collected on the filter, in 20 millilitres of nitric acid; add about 0.5 gramme of urea, warm on a water-bath, dilute to about 60 millilitres, and add N/10 potassium permanganate until a permanent pink colour is obtained. Decolourise with a few drops of ferrous sulphate solution, and titrate with N/10 ammonium thiocyanate, using ferric ammonium sulphate as indicator. Each millilitre of N/10 ammonium thiocyanate is equivalent to 0.01003 gramme of Hg.

For bromine. Mix 0.3 gramme in a porcelain crucible with 1 gramme of potassium nitrate, 2 grammes of potassium carbonate and 2 grammes of anhydrous sodium carbonate, and cover the surface with 2 grammes of a mixture of equal parts of anhydrous sodium and potassium carbonates; heat gently for twenty minutes, and finally heat strongly until completely fused; dissolve the cooled mass in water, acidify with nitric acid, add 20 millilitres of N/10 silver nitrate, and titrate with N/10 ammonium thiocyanate, using ferric ammonium sulphate as indicator; each millilitre of N/10 silver nitrate is equivalent to 0.007992 gramme of Br.

Test for Toxicity.—Mercurochrome has a toxicity, when injected intravenously into mice, which does not exceed the toxicity of the standard preparation of mercurochrome. The standard preparation of mercurochrome is a quantity of mercurochrome kept by the Pharmaceutical Society of Great Britain. The comparison between the toxicity of a sample of mercurochrome and that of the standard preparation is made in the following way. The average lethal dose of the standard preparation is first determined by injecting mice with the standard preparation. The mice should be, as far as possible, of the same weight, and should not differ by more than 8 grammes; they are prepared by removing food from their cages on the evening before they are to be injected; a solution of the standard preparation is made in freshly-distilled water, and is injected into each mouse by way of a tail vein. The volume injected is adjusted according to the body weight, so that 0.4 millilitre is given per 20 gramme weight of mouse. After they are injected, the mice are given food and observed during seven days to determine the number of mice which die. The average lethal dose is that dose which kills exactly one-half of a group of not less than thirty mice. A dose of the sample being tested equal to the average lethal dose of the standard preparation is then injected into each of ten mice, taking the precautions described. If not more than two mice die, the sample passes the test. When more than two mice die, the same dose of the sample being tested is injected into each of ten more mice. If the number of mice which die out of the twenty mice

injected is not greater than eight, the sample being tested passes the test, if, however, the number of mice which die is greater than fifteen the sample being tested is rejected. When the number of deaths is more than eight, but less than fifteen, a third group of ten mice is given the same dose of the sample being tested. If the number of mice which die out of the thirty mice injected is not greater than fifteen, the sample being tested passes the test; if the number is greater than fifteen, the sample being tested fails to pass the test.

Action and Uses.—Mercurochrome has been stated to possess a high degree of bactericidal action *in vitro*, but laboratory experiments indicate that it is relatively weak in its action. It is significant that it was introduced as a urinary antiseptic, and that the experiments were made in an acid medium. Mercurochrome is a more powerful antiseptic in an acid medium than in a neutral or alkaline medium, and it has been suggested that this feature is due to decomposition by acid with formation of mercuric compounds. It would appear that its use intravenously as an antiseptic is of no value, although it has been used by this route in obstinate cases of *B. coli* pyelitis, in gonorrhœa and in septicæmia. As it is excreted partly in the bile, its use has been advocated as a biliary antiseptic. For irrigation of the bladder in cystitis, and of the urethra in gonorrhœa, its use in 1 per cent. solution has been much vaunted, and good results claimed.

As a local application to ulcers, erysipelas and cellulitis, mercurochrome has its advocates, although laboratory experiments indicate that it possesses only a feeble bactericidal action towards both streptococci and staphylococci. For local application to wounds, a 1 to 4 per cent. w/v solution in water may be employed, and for skin sterilisation, a 2 per cent. w/v solution in a mixture of water, 3 parts, alcohol, 55 parts, and acetone, 10 parts, has been recommended. Absorbent gauze containing about 0.1 per cent. of mercurochrome has been used as a dressing. 2 to 5 milligrams per kilogram of body-weight, as a 0.5 per cent. solution, may be used intravenously, although injections of this amount should not be given at more frequent intervals than three days. Its toxicity may be reduced by the addition of dextrose to the solution immediately before injection. Acute mercurial poisoning is said to have been observed after the intravenous administration of mercurochrome. Solutions of mercurochrome for **injection** should be prepared by aseptic methods. Mercurochrome is **incompatible** with acids, the salts of most alkaloids, and with many local anæsthetics.

METHYLACETANILIDUM

(Methylacetanilid.)

Methylacetanilide

Methylacetanilide, $\text{C}_6\text{H}_5\text{N}(\text{CH}_3)\text{OC}\cdot\text{CH}_3$, may be prepared by treating monomethylaniline with acetic anhydride. When the reaction is

completed, the acicular crystals formed after cooling are collected and recrystallised from boiling water or dilute alcohol. It occurs in the form of colourless crystals, having a slightly saline taste. It readily forms supersaturated solutions in water. On heating with sodium hydroxide or sulphuric acid, it is decomposed into acetic acid and monomethylaniline, which, on treatment with solution of nitrous acid, yields a nitroso-compound which is insoluble in sodium hydroxide.

Soluble in water (1 in 60), boiling water (1 in 2), chloroform (1 in 2) and ether (1 in 10); very easily soluble in alcohol, both strong and diluted.

Standard.—Methylacetanilide melts between 100° and 101° . Ash, not more than 0.1 per cent.

Action and Uses.—Methylacetanilide resembles acetanilide, but its action is more powerful. It is used as an analgesic and antispasmodic for the relief of pain in neuralgia, sciatica and migraine. Methylacetanilide may be **administered** in solution in water, or in cachets or pills. It is not advisable to exceed 2 grains for a single dose. In case of **poisoning**, an emetic should be given, followed by stimulants and artificial respiration.

Dose.—0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains).

METHYLIS SALICYLAS

(Methyl. Salicyl.)

Methyl Salicylate

Methyl salicylate, $\text{C}_6\text{H}_4(\text{OH})\cdot\text{COOCH}_3$, is the methyl ester of salicylic acid, and may be prepared by dissolving salicylic acid in methyl alcohol, then gradually adding sulphuric acid, warming for about twenty-four hours, and distilling in a current of steam. It occurs as a colourless or pale yellow, oily liquid, with a strong, characteristic, aromatic odour, and a warm, sweet, aromatic taste. The aqueous solution is neutral or slightly acid to litmus, and yields an intense violet colouration on the addition of a trace of ferric chloride.

Slightly **soluble** in water; miscible with alcohol (90 per cent.), ether, chloroform, glacial acetic acid, carbon disulphide, and fixed and volatile oils.

Standard, B.P.—Methyl salicylate contains not less than 98 per cent. of $\text{C}_8\text{H}_8\text{O}_3$. Specific gravity, 1.186 to 1.191; refractive index at 20° , 1.536 to 1.538. It is soluble in 10 volumes of alcohol (70 per cent.), and complies also with a limit test for free acid.

Action and Uses.—Methyl salicylate has the general action of salicylates; in addition, it is readily absorbed when rubbed on the skin. The drug is occasionally given internally, when it should be dispensed

in capsules, preferably with an inert oil as diluent. It is applied **externally** in lumbago, sciatic and rheumatic conditions, either alone, or as a liniment, or as an ointment with a basis of lanolin. The undiluted substance may be painted on the skin and covered with oiled silk or gutta-percha tissue, or it may be mixed with an equal volume of oil and applied with gentle friction, or on lint. It is used as a flavouring agent in mouth-washes and tooth pastes. The symptoms of **poisoning** with methyl salicylate are those of acidosis, and should be treated by the administration of alkalis, dextrose and insulin.

Dose.—0.3 to 1 millilitre (5 to 15 minims).

ETHYLIS SALICYLAS.—Ethyl salicylate, $C_6H_4(OH) \cdot COOC_2H_5$, may be prepared by the esterification of ethyl alcohol with salicylic acid. It occurs as a transparent, colourless liquid, having an odour similar to that of the methyl ester and boiling at about 230° . It is used for the same purposes as methyl salicylate but is said to be less toxic and less irritant in its action. **Dose.**—0.3 to 0.6 millilitre (5 to 10 minims).

AMYLIS SALICYLAS.—Amyl salicylate, $C_6H_4(OH) \cdot COOC_5H_{11}$, may be prepared by the esterification of amyl alcohol with salicylic acid. It occurs as a colourless oil, having a powerful, fragrant odour, a specific gravity of about 1.055 and a boiling-point of about 278° . It is used in perfumery, particularly in the preparation of synthetic carnation perfumes.

Preparations

Linimentum Methylis Salicylatis, B.P.C.—(Lin. Methyl. Salicyl.)—Liniment of Methyl Salicylate. *Syn.*—Linimentum Betulæ Compositum; Compound Liniment of Birch. Rectified oil of camphor, 1 in 4, with menthol, oil of eucalyptus and methyl salicylate.

Linimentum Methylis Salicylatis Compositum, B.P.C.—(Lin. Methyl. Salicyl. Co.)—Compound Liniment of Methyl Salicylate. Rectified oil of camphor, 1 in 4, with menthol, chloral hydrate, methyl salicylate and chlorophyll.

Linimentum Methylis Salicylatis Oleosum, B.P.C.—(Lin. Methyl. Salicyl. Oleos.)—Liniment of Methyl Salicylate with Oil. *Syn.*—Linimentum Methylis Salicylatis Simplex. Methyl salicylate, 1 in 4, with rape oil.

Unguentum Methylis Salicylatis, B.P.C.—(Ung. Methyl. Salicyl.)—Methyl Salicylate Ointment. *Syn.*—Unguentum Methylis Salicylatis Forte; Strong Methyl Salicylate Ointment. Methyl salicylate, 50 per cent., in white beeswax and hydrous wool fat.

Unguentum Methylis Salicylatis Compositum, B.P.C.—(Ung. Methyl. Salicyl. Co.)—Compound Methyl Salicylate Ointment. *Syn.*—Unguentum Methylis Salicylatis Compositum Forte; Strong Compound Ointment of Methyl Salicylate; Unguentum Betulæ Compositum; Unguentum Analgesicum, Analgesic Balsam. Methyl salicylate, 50 per cent., and menthol, 10 per cent., with eucalyptol and oil of capuput, in white beeswax and hydrous wool fat.

Unguentum Methylis Salicylatis Compositum Dilutum, B.P.C.—(Ung. Methyl. Salicyl. Co. Dil.)—Dilute Compound Methyl Salicylate Ointment. Compound methyl salicylate ointment, 25 per cent., in hydrous wool fat ointment.

Unguentum Methylis Salicylatis Dilutum, B.P.C.—(Ung. Methyl. Salicyl. Dil.)—Dilute Methyl Salicylate Ointment. Methyl salicylate ointment, 25 per cent., in hydrous wool fat ointment.

METHYLSULPHONAL

(Methylsulphonal)

Methylsulphonal

Methylsulphonal, $(\text{CH}_3)(\text{C}_2\text{H}_5)\text{C}(\text{SO}_2\cdot\text{C}_2\text{H}_5)_2$, is diethylsulphone-methylethylmethane, and is prepared by the interaction of methyl-ethylketone and ethyl mercaptan, and oxidising the resulting mercaptol with potassium permanganate; the product is then purified by re-crystallisation from boiling water. Methylsulphonal occurs in the form of colourless, odourless, lustrous, crystalline scales, or as a crystalline powder, with a slightly bitter taste. When heated alone, it is decomposed, with evolution of sulphur dioxide; heated with anhydrous sodium acetate, hydrogen sulphide is given off; heated with powdered charcoal, the unpleasant odour of mercaptan is evolved.

Soluble in water (1 in 320), alcohol (90 per cent.) (1 in 12), and in ether.

Standard, B.P.—Methylsulphonal has a melting-point of 76° to 78° . Ash, not more than 0.05 per cent. It complies also with limit tests for free acid, and for readily oxidisable substances.

Action and Uses.—Methylsulphonal is a hypnotic resembling sulphonal, but is more rapid in its action. It has the disadvantages of slow excretion and ready accumulation exhibited by sulphonal, and hence is rarely used. It is best **administered** in cachets, swallowed with a large draught of hot liquid. In cases of **poisoning**, excretion can be assisted by giving alkaline liquids.

Dose.—0.3 to 1.2 grammes (5 to 20 grains).

METHYLTHIONINÆ CHLORIDUM

(Methylthionin. Chlor.)

Methylene Blue

Synonym—Methylthionine Chloride.

Methylene blue is tetramethylthionine chloride, and may be prepared by treating dimethyl-*p*-phenylenediamine with an oxidising agent in the presence of sodium thiosulphate; the thiosulphonic acid thus obtained is further oxidised in the presence of dimethylaniline and the product boiled with acid to yield the leuco-compound, from which methylene blue is obtained by treatment with ferric chloride. It occurs as an almost odourless, dark greenish, crystalline powder, with a metallic lustre, or as a dull, dark green or brown powder. An aqueous

solution, 1 in 10,000, is of a clear, deep blue colour, and responds to the following tests: the colour is discharged when the solution is warmed with zinc powder and acetic acid, but reappears when the liquid is filtered and exposed to the air; on the addition of potassium iodide, a deep blue, flocculent precipitate is formed and settles slowly, leaving a blue, supernatant liquid; when a few drops of N/10 solution of potassium dichromate are added to the aqueous solution, slightly acidified with dilute sulphuric acid, a bluish-violet precipitate is formed, the liquid becoming reddish-violet, and the blue colour is restored on the addition of sulphurous acid; on the addition of a few drops of a solution of iodine, a deep brown colouration is produced, the blue colour being restored on the addition of a few drops of sodium thio-sulphate solution. Commercial methylene blue is the double chloride of tetramethylthionine and zinc, and is not suitable for medicinal use.

Soluble in water (about 1 in 50), alcohol (90 per cent.) and chloroform.

Standard, B.P.—Methylene blue contains not less than 80 per cent. of $C_{16}H_{18}N_3ClS$. Arsenic limit, 10 parts per million. It complies also with a limit test for zinc.

Action and Uses.—Methylene blue is slightly antiseptic, and when taken internally it is excreted almost entirely by the kidneys. For this reason it is employed in such infections as gonorrhœa and catarrhal inflammation of the bladder. *In vitro*, it has a marked trypanocidal action, and destroys protozoa and parasitic worms. It was formerly employed as an analgesic in migraine, neuralgia, sciatica and other rheumatic affections, but it is of doubtful value in these conditions. It has also been used in cases of malaria where quinine is tolerated badly, but it is much inferior to alkaloids of cinchona. Methylene blue has some curative value in the treatment of piroplasmiasis, but is inferior to trypan blue. In large doses methylene blue is irritating. The drug is **administered** usually in the form of pills, capsules, or tablets, which should be taken with a draught of water. A lotion containing 0.25 per cent. w/v of the dye has been used in ozæna, and irrigations with solutions 1 in 1000 to 1 in 500 have been employed in cystitis.

A solution of methylene blue is injected intramuscularly as a test for permeability of the kidney. Cystoscopic observations are made of the first appearance of the dye in the urine. In normal conditions of the kidney, the urine assumes a greenish colour in about thirty minutes. The rate of excretion serves as an indication of the degree of renal lesion. Solutions for **injection** may be sterilised by heating in an autoclave or by tyndallisation. Solutions of methylene blue are largely used as stains for bacteria, Lœffler's alkaline solution being employed as a counterstain for acid-fast bacteria, and Neisser's acid solution being used as a stain for diphtheria bacilli. Methylene blue stains on the skin or on fabrics may be removed by the use of solution of chlorinated soda.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

METHYLVIOLA

(Methylviola)

Methyl Violet*Synonym*—Methyl Rosaniline.

Methyl violet (Colour Index No. 680) is a mixture of the hydrochlorides of the more highly methylated pararosanilines, containing principally tetra-, penta-, and hexamethylpararosanilines, formed by air oxidation of dimethylaniline and phenol, in the presence of sodium chloride and copper sulphate. It occurs as a greenish mass with a metallic lustre, or as a green, crystalline powder. It is precipitated from aqueous solution by tannic acid, and is decolourised by the action of hydrochloric acid and zinc powder, a blue colour being produced on the further addition of a slight excess of ammonia. On the gradual addition of hydrochloric acid to a 0·2 per cent. aqueous solution, the colour is changed through bluish-green and green to brownish-yellow, and on further dilution of the solution the colours are restored in reverse order. The colour base is precipitated by alkalis.

Soluble in water (1 in 20), glycerin (1 in 16), alcohol (1 in 20), the solution having a violet colour and being decomposed by exposure to light; insoluble in ether.

Standard.—Methyl violet leaves not more than 5 per cent. of sulphated ash. Arsenic limit, 10 parts per million. Not more than 1 per cent. is insoluble in boiling alcohol (limit of dextrin). Dissolve the sulphated ash from 1 gramme in 20 millilitres of water and 2 millilitres of dilute hydrochloric acid, and add 1 millilitre of potassium ferrocyanide solution; no precipitate is produced (limit of zinc).

Action and Uses.—Methyl violet is a powerful antiseptic. It is rarely used in medicine, but is employed as a bacteriological stain. For local use in gynaecological practice, and for administration intravenously in the treatment of staphylococcal septicæmia, crystal violet should be used (see *Viola Crystallina*).

MEZEREUM

(Mezer.)

Mezereon*Synonym*—Mezèreon Bark.

Mezereon consists of the dried bark obtained from *Daphne Mezereum* Linn. and *D. Laureola* Linn., both indigenous to Britain, and from *D. Gnidium* Linn. (Fam. Thymelæaceæ), indigenous to Southern Europe and Algeria.

The bark occurs in long, thin, flattened or quilled, very tough and occurle strips, about 0·5 to 2 centimetres wide, and having a papery cork a met. easily separates. The outer surface of the bark of *D. Mezereum* is

olive-brown or yellowish and finely wrinkled transversely, that of the stem showing scattered, rounded scars of buds and leaves; the inner surface is smooth, whitish or yellowish, and silky, and the fracture is tough and fibrous. The cortex of the stem is green and that of the root is yellowish. The outer surface of the bark of *D. Laureola* is purplish-grey, the scars of the buds and leaves being pointed-oval and crowded at intervals. It is odourless, and the taste is persistent, burning and acrid.

Mezereon **contains** a greenish-brown, amorphous, acrid resin (mezelein), which readily changes into a bitter, acid resin (mezeleic acid). The crystalline, bitter glycoside, daphnin, fixed oil, and a substance resembling euphorbone have also been isolated, but none of these is acrid.

Standard.—Mezereon yields not more than 2 per cent. of acid-insoluble ash.

Mezereon, in powder (Pulvis Mezerci : Pulv. Mezer.), contains the constituents of Mezereum, and complies with the standard for the unground drug.

Action and Uses.—Mezereon is not much used medicinally. It is an ingredient of Decoctum Sarsæ Compositum Concentratum. Applied externally, it is stimulant and vesicant.

MORPHINA

(Morph.)

Morphine

Morphine is the principal alkaloid occurring in opium, in which it exists in combination with meconic acid and sulphuric acid to the extent of from 8 to 20 per cent. or even more. It may be isolated by various methods, the final step usually being the addition of ammonia in slight excess to an acid solution of the base, the precipitate being washed with water until free from ammonium salt, and recrystallised from boiling alcohol.

It occurs in fine, odourless, colourless or white, needle-shaped crystals, or as a white, crystalline powder, permanent in air and having a bitter taste. Its aqueous solution is alkaline to litmus and is laevorotatory. It loses its water of crystallisation at about 100°, and melts with decomposition above 230°. The morphine molecule contains two hydroxyl groups, one of which is phenolic, and by interaction with alkyl halides and analogous compounds it yields derivatives which are known as ethers; by interaction with acids, acyl and similar radicles may be introduced with formation of esters. Codeine and ethylmorphine in this respect are ethers, whilst diamorphine is an ester. The esters are readily hydrolysed, but the ethers are more stable.

Dilute solutions of morphine in a slight excess of sulphuric acid

give a brown colouration on adding a saturated solution of potassium iodate and allowing to stand for a few minutes, the colour being intensified by the addition of excess of ammonia. Very dilute solutions in decinormal hydrochloric acid yield a yellowish-brown colour on the addition of sodium nitrite solution followed by excess of ammonia. These two reactions are used for the purpose of determining very small amounts of the alkaloid colorimetrically. The solid alkaloid, when moistened with ferric chloride solution, gives a deep greenish-blue colour; it also gives an orange-red colour with nitric acid, and a violet colour with sulphomolybdic acid. Morphine solutions added to potassium ferricyanide solution containing a drop of neutral ferric chloride give a deep blue solution which, on standing, throws down a blue precipitate (distinction from codeine).

Soluble in water (1 in 5000), boiling water (about 1 in 400), alcohol (1 in 100), boiling alcohol (1 in 14), chloroform (1 in 4000) and benzene (1 in 3250); almost insoluble in ether and ethyl acetate, and not very soluble in amyl alcohol; soluble in oleic acid (1 in 10), glycerin (1 in 125), and in solutions of the caustic alkalis, but very sparingly soluble in ammonia and the alkali carbonates; soluble in acids to form crystalline salts, from solutions of which it is precipitated by ammonia but not by potassium hydroxide.

Standard.—Morphine loses on drying at 110° not more than 7 per cent. of its weight. Ash, not more than 0.1 per cent. A solution in dilute hydrochloric acid complies with the limit test for other alkaloids in *Morphinæ Hydrochloridum*, using three-quarters of the weight there specified.

Action and Uses.—Morphine and its salts differ from other hypnotics in that they depress sensory nerve cells in the cerebrum, while most other hypnotics paralyse motor and sensory cells simultaneously. Because of this action on the cerebral hemispheres, morphine is the most valuable drug for the treatment of pain. It is of great value as a remedy for sleeplessness due to painful disease. For internal hæmorrhage, injections of morphine form a routine treatment; they act by soothing the patient, stopping restlessness, and so keeping blood pressure low. In acute febrile disease, especially where sleep is delayed, morphine is invaluable; it is used in the treatment of pneumonia and in conditions where normally the drug might even be contra-indicated, it being considered that the benefit secured by relief of pain and sleeplessness, with their attendant exhaustion, may more than compensate any disadvantage. It is less valuable in the treatment of mania, epilepsy and chorea than many other narcotics. Morphine depresses the medulla generally, including the respiratory centre, diminishes gaseous metabolism, and is used to arrest useless cough, but its employment is contra-indicated in conditions where there is much expectoration. It is largely prescribed with expectorants in the coughs of phthisis. It is useful in cases of acute asthma, and gives relief in hiccup. Occasionally it causes nausea and vomiting, and with some individuals this action would appear to be an idiosyncrasy

Since morphine has a specific action on the alimentary canal, diminishing peristalsis, it is employed in the treatment of diarrhœa and colic, especially that due to lead. In peritonitis it is especially valuable, diminishing the pain, restlessness and peristaltic movements; it should not be given, however, until a diagnosis has been made. Morphine has few peripheral actions, it does not affect the heart or peripheral circulation, and so is invaluable in the insomnia of cardiac disease. It has no effect on the kidneys, but is better avoided in renal disease on account of its constipating effect. Morphine tends, in general, to diminish secretions, but, since it dilates skin vessels, the excretion of sweat is increased. In diarrhœa, opium is preferred to morphine; for the relief of pain, morphine is preferable. Morphine constipates chiefly by contracting the pyloric and ileo-cæcal valves; opium constipates in the same way with the addition of a general relaxation of the rest of the intestinal muscle brought about by the narcotine and papaverine.

Tolerance to morphine is caused by the greater ability of the tissues to oxidise the alkaloid. The danger of habit-forming is very real, and great discrimination is required in prescribing the drug. Addicts require increasing quantities to satisfy their craving, and enormous doses are sometimes needed to produce the effect desired. Children and the aged are especially susceptible to morphine, and it must be prescribed for them with the very greatest care. It has, however, been stated frequently that the susceptibility in children applies only to infants still at the breast, and that after one year it appears to pass off.

For **internal** administration, the soluble salts of morphine are usually dispensed. The alkaloid is employed only when oily solutions are required. For the preparation of a solution in oil, the alkaloid is usually dissolved in ten times its weight of oleic acid, and the oleate so formed mixed with the oily vehicle; ointments containing 2 to 5 per cent. of morphine may be prepared similarly. Acute morphine **poisoning** has to be distinguished from certain cerebral conditions, intoxication, concussion and hæmorrhage; the equal pin-point pupils which do not react to light form a valuable aid in diagnosis. Treatment of poisoning by morphine consists in washing out the stomach with dilute potassium permanganate solution two or three times at intervals of thirty minutes. Artificial respiration and inhalation of oxygen must be employed if necessary. Atropine, hot coffee, caffeine, or strychnine may be used to excite the respiratory centre.

Dose.—0.008 to 0.02 gramme ($\frac{1}{8}$ to $\frac{1}{3}$ grain).

MORPHINÆ ACETAS

(Morph. Acet.)

Morphine Acetate

Morphine acetate may be prepared by neutralising freshly precipitated morphine, diffused in water, with acetic acid, evaporating on a

water-bath until the solution solidifies on cooling and, finally, carefully drying the salt at a gentle heat, when it may be powdered. It cannot be dried without some little decomposition occurring, acetic acid being liberated. It occurs as a white or yellowish-white, amorphous or crystalline powder, having a faintly acetous odour, especially when the vessel containing it is freshly opened. Samples which have been kept for any length of time become basic, owing to loss of acetic acid, and brownish in colour. In making aqueous solutions, a little free acetic acid is usually required to replace that lost during spontaneous decomposition. The alcoholic solution when mixed with ether deposits crystals of the base, free acetic acid remaining in solution. When heated, the salt loses water and acetic acid, and melts at about 200°. It contains the equivalent of about 71 per cent. of anhydrous morphine. In neutral solutions, ferric chloride produces a blue colour which is destroyed by acids, alcohol, or by heating. It yields the colour reactions given under *Morphina*. It should be **stored** in well-stoppered, amber-coloured bottles.

Soluble in water (1 in 2·5), alcohol (1 in 100) and glycerin (1 in 5); insoluble in ether.

Standard.—Morphine acetate leaves not more than 0·1 per cent. of ash. It complies with the limit test for other alkaloids in *Morphinæ Hydrochloridum*.

Action and Uses.—Morphine acetate has the general medicinal properties of the salts of morphine, but is little used owing to the tendency, both of the salt and its solutions, to undergo change. It may be administered as *Liquor Morphinæ Acetatis*. Solutions for **injection** may be sterilised by tyndallisation or by filtration. The containers should comply with the tests for limit of alkalinity of glass, and the solution should be stored protected from light. Morphine acetate is **incompatible** with solution of ammonia and vegetable astringents. In cases of **poisoning** by morphine acetate, the antidotes are those described for *Morphina*.

Dose.—0·008 to 0·02 gramme ($\frac{1}{8}$ to $\frac{1}{3}$ grain).

Preparation

Liquor Morphinæ Acetatis, B.P.C.—(*Liq. Morph. Acet.*)—Solution of Morphine Acetate. Morphine acetate, 1 per cent. w/v, in dilute acetic acid alcohol (90 per cent.) and distilled water. Dose.—0·3 to 2 millilitres (5 to 30 minims).

This solution was included in the British Pharmacopæia, 1914.

MORPHINÆ HYDROCHLORIDUM

(*Morph. Hydrochlor.*)

Morphine Hydrochloride

*Morphine hydrochloride may be prepared by neutralising morphine,

suspended in hot water, with diluted hydrochloric acid, concentrating the solution and setting it aside to crystallise. Morphine hydrochloride occurs in colourless, odourless, glistening needles or as a crystalline powder, with a bitter taste, and contains about 76 per cent. of anhydrous morphine. The aqueous solution is neutral to litmus and, on the addition of solution of ammonia, yields a white precipitate which dissolves on adding sodium hydroxide solution. It loses its water of crystallisation when heated at 100° , and chars at higher temperatures without melting. When morphine hydrochloride in powder is sprinkled on the surface of a few drops of nitric acid, an orange-red colour is produced; when added to sulphuric acid, containing a trace of solution of formaldehyde, a purple colour is produced. When a small quantity of morphine hydrochloride is heated with sulphuric acid on a water-bath for fifteen minutes, the resulting solution, when cooled and treated with a few drops of dilute nitric acid, gives a blood-red colouration. On the addition of 1 drop of ferric chloride solution to a 1 in 50 aqueous solution, a blue colour is produced.

Morphine hydrochloride may be distinguished from codeine by the immediate production of a bluish-green colour on the addition of potassium ferricyanide solution containing a trace of ferric chloride. A dilute aqueous solution, slightly acidified with dilute sulphuric acid, gives with potassium iodate solution a brown colouration reaching maximum intensity in about five minutes; on the addition of solution of ammonia, the colour changes nearly to black. This reaction serves to distinguish morphine from both codeine and diamorphine. Morphine hydrochloride should be **stored** in well-closed containers and protected from light.

Soluble in water (1 in 25), boiling water (1 in 1), alcohol (90 per cent.) (1 in 50), glycerin (1 in 8). Insoluble in ether and chloroform.

Standard, B.P.—Morphine hydrochloride loses on drying at 120° not more than 14.5 per cent. of its weight, the dried material being not more than faintly yellow in colour. Ash, not more than 0.1 per cent. It complies also with limit tests for other alkaloids and for readily-carbonisable substances.

Action and Uses.—Morphine hydrochloride has the general medicinal properties of the salts of morphine. It is one of the most stable salts of the alkaloid and, where its solubility permits, it is preferred to the salts of the organic acids. *Liquor Morphinae Hydrochloridi* is the most convenient preparation for general **administration**. Atropine sulphate ($\frac{1}{200}$ or $\frac{1}{100}$ grain) is frequently added to morphine injections to increase their analgesic effect, to lessen their tendency to cause constipation, and especially to reduce spasm. A solution for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. The containers should comply with the tests for limit of alkalinity of glass, and the solution should be stored protected from light. For use as mildly sedative and expectorant lozenges, *Trochiscus Morphinae* and *Trochiscus Morphinae et Ipecacuanhae* are suitable.

Morphine hydrochloride is sometimes given in pills, prepared by triturating it with lactose and massing with syrup of liquid glucose. Insufflatio Bismuthi et Morphinæ is used in nasal catarrh. Morphine hydrochloride is **incompatible** with solution of ammonia and vegetable astringents. In cases of **poisoning** by morphine hydrochloride, the antidotes are those described for Morphina.

Dose.—0.008 to 0.02 gramme ($\frac{1}{8}$ to $\frac{1}{2}$ grain).

Preparations

Injectio Morphinæ, B.P.C.—(Inj. Morph.)—Injection of Morphine. It contains 2.5 per cent. w/v of morphine hydrochloride; 0.6 millilitre contains 0.015 gramme, and 10 minims contains about $\frac{1}{4}$ grain, of morphine hydrochloride. **Dose.**—0.3 to 0.6 millilitre (5 to 10 minims), by subcutaneous injection.

This injection, prepared with 2.5 per cent. w/v of morphine tartrate, was included in the British Pharmacopæia, 1914, under the name of Injunctio Morphinæ Hypodermica.

Insufflatio Bismuthi et Morphinæ, B.P.C.—(Insuff. Bism. et Morph.)—Bismuth and Morphine Insufflation. *Syn.*—Ferrier's Snuff; Bismuth and Morphine Snuff. Bismuth subnitrate, 75 per cent., and morphine hydrochloride, 0.4 per cent., with acacia.

Liquor Morphinæ Hydrochloridi, B.P.—(Liq. Morph. Hydrochlor.)—Solution of Morphine Hydrochloride. It contains 1 per cent. w/v of morphine hydrochloride (limits, 0.95 to 1.05) in dilute hydrochloric acid, alcohol (90 per cent.) and distilled water. 2 millilitres contains 0.02 gramme, and 30 minims contains about $\frac{1}{4}$ grain, of morphine hydrochloride. **Dose.**—0.3 to 2 millilitres (5 to 30 minims).

Mistura Chloroformi Composita, B.P.C.—(Mist. Chlorof. Co.)—Compound Chloroform Mixture. *Syn.*—Mistura Tussi Sedativa; Mistura Tussi Rubra. Each fluid drachm contains 15 minims of dilute hydrobromic acid and $\frac{3}{8}$ grain of morphine hydrochloride, with chloroform, solution of bordeaux B, cherry-laurel water, syrup of tolu and syrup. **Dose.**—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Suppositorium Morphinæ, B.P.—(Supp. Morph.)—Morphine Suppository. Each suppository contains 0.015 gramme ($\frac{1}{4}$ grain) of morphine hydrochloride.

Tinctura Chloroformi et Morphinæ, B.P.C.—(Tinct. Chlorof. et Morph.)—Tincture of Chloroform and Morphine. *Syn.*—Chlorodyne; Tinct. Chlorof. et Morph. B.P. 1885. Chloroform, 1 in 8, morphine hydrochloride, about 1 in 450, and dilute hydrocyanic acid, about 1 in 16, with ether, alcohol (90 per cent.), oil of peppermint, liquid extract of liquorice, treacle and syrup. **Dose.**—0.3 to 0.6 millilitre (5 to 10 minims).

Tinctura Chloroformi et Morphinæ Composita, B.P.C.—(Tinct. Chlorof. et Morph. Co.)—Compound Tincture of Chloroform and Morphine. Chloroform, about 1 in 13, morphine hydrochloride, 1 in 100, with dilute hydrocyanic acid, about 1 in 20, tincture of capsicum, tincture of cannabis, oil of peppermint, glycerin and alcohol (90 per cent.). **Dose.**—0.3 to 1 millilitre (5 to 15 minims).

This tincture was included in the British Pharmacopæia, 1914.

Trochisci Chlorodini, B.P.C.—(Troch. Chlorod.)—Chlorodyne Lozenges. Each lozenge contains about $\frac{1}{16}$ grain of morphine hydrochloride with chloroform, ether, oil of peppermint and tincture of capsicum.

Trochisci Morphinæ, B.P.C.—(Troch. Morph.)—Morphine Lozenges. Each lozenge contains about $\frac{3}{16}$ grain of morphine hydrochloride.

This lozenge, containing 0.002 gramme of morphine hydrochloride, was included in the British Pharmacopæia, 1914.

Trochiscus Morphinae et Ipecacuanhae, B.P.—(Troch. Morph. et Ipecac.)—Lozenge of Morphine and Ipecacuanha. *Syn.*—Morphine and Ipecacuanha Lozenge. Each lozenge contains approximately 0.002 gramme or $\frac{1}{50}$ grain of morphine hydrochloride and approximately 0.006 gramme or $\frac{1}{16}$ grain of powdered ipecacuanha.

MORPHINÆ SULPHAS

(Morph. Sulph.)

Morphine Sulphate

Morphine sulphate may be prepared by neutralising morphine with dilute sulphuric acid. It occurs in white, odourless, acicular crystals, or in cubical masses, permanent in the air, and having a bitter taste. It contains the equivalent of about 75 per cent. of anhydrous morphine. It loses three molecules of water at 100°. When heated to about 250° the salt assumes a brown colour, and then chars without melting. Its solution is neutral to litmus, and yields, on the addition of ammonia, a precipitate which responds to the tests for morphine.

Soluble in water (1 in 21) and alcohol (1 in 700); insoluble in ether and chloroform.

Standard.—Morphine sulphate loses on drying at 130° not more than 12 per cent. of its weight. Ash, not more than 0.1 per cent. It complies with the limit test for other alkaloids in Morphinæ Hydrochloridum.

Action and Uses.—Morphine sulphate has the general properties of the salts of morphine and is one of the most suitable salts for hypodermic injection. It is sometimes given with atropine sulphate and hyoscine hydrobromide as a preliminary to general anaesthesia, and with hyoscine hydrobromide it is used to produce "twilight sleep." Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. The containers should comply with the tests for limit of alkalinity of glass, and the solution should be stored protected from light. Morphine sulphate is **incompatible** with solutions of ammonia and vegetable astringents. In cases of **poisoning** by morphine sulphate, the antidotes are those described for Morphina.

Dose.—0.008 to 0.02 gramme ($\frac{1}{8}$ to $\frac{1}{2}$ grain).

MORPHINÆ TARTRAS

(Morph. Tart.)

Morphine Tartrate

Morphine tartrate may be prepared by neutralising morphine, suspended in water, with tartaric acid, and crystallising the solution.

It occurs in neutral, odourless, minutely acicular crystals, with a bitter taste, and contains the equivalent of about 74 per cent. of anhydrous morphine. It effloresces on exposure to air, becoming anhydrous at 100°. Morphine tartrate responds to the tests described under morphine hydrochloride, the tests with sulphuric acid being carried out on the alkaloidal base separated by the addition of ammonia to the aqueous solution. It should be **stored** in well-closed containers and protected from light.

Soluble in water (1 in 11) and alcohol (90 per cent.) (1 in 600); almost insoluble in ether and chloroform.

Standard, B.P.—Morphine tartrate loses on drying at 100° not more than 7 per cent. of its weight. Ash, not more than 0.1 per cent. It complies also with a limit test for other alkaloids.

Action and Uses.—Morphine tartrate has the general properties of the salts of morphine. Liquor Morphinæ Tartratis is used similarly to the corresponding solution of morphine hydrochloride. Solutions for **injection** may be sterilised by tyndallisation or by filtration. The containers should comply with the tests for limit of alkalinity of glass, and the solution should be stored protected from light. Morphine tartrate is **incompatible** with solutions of ammonia and vegetable astringents. In cases of **poisoning** by morphine tartrate, the antidotes are those described for Morphina.

Dose.—0.008 to 0.02 gramme ($\frac{1}{8}$ to $\frac{1}{3}$ grain).

Preparation

Liquor Morphinæ Tartratis, B.P.C.—(Liq. Morph. Tart.)—Solution of Morphine Tartrate. Morphine tartrate, 1 per cent. w/v, in alcohol (90 per cent.) and distilled water. Dose.—0.3 to 2 millilitres (5 to 30 minims).

This solution was included in the British Pharmacopæia, 1914.

MORUS

(Morus)

Mulberry

Mulberry is the fresh, ripe fruit of *Morus nigra* Linn. (Fam. Moraceæ); it is cultivated in Great Britain.

The fruit is a dark purplish-black, globular sorosis, about two centimetres long and slightly less in diameter; it consists of about 40 small, individual fruits, each of which is an achene surmounted by two stigmas, and surrounded by four succulent and confluent perianth parts. The taste is sweet and acidulous. Mulberry **contains** about 10 per cent. of invert sugar, malic and citric acids, colouring matter, pectin, etc.

Action and Uses.—The juice of mulberry is slightly laxative and expectorant, but it is used chiefly as an adjuvant, in the form of *Syrupus Mori*.

RIBES NIGRUM.—Black currant is the fresh, ripe fruit of *Ribes nigrum* Linn. (Fam. Saxifragaceæ), a shrub of the same habitat as the red currant. The fruit is also similar but larger, being about ten millimetres in diameter and bluish-black in colour. The taste is pleasantly acidic and the aroma strong. Black currant contains about 3 to 4 per cent. of invert sugar, malic and citric acids, pectin and colouring matter. The juice is employed as a flavouring and colouring agent and in the preparation of pastilles and syrups. Black currant, imported or stored in metal containers, may contain excessive quantities of lead and tin.

RIBES RUBRUM.—Red currant is the fresh ripe fruit of *Ribes rubrum* Linn. (Fam. Saxifragaceæ), a shrub cultivated in Britain and in temperate parts of Europe and America. The fruit is a succulent berry, about six millimetres in diameter, spherical, bright red in colour, with a smooth surface, beneath which vascular strands are visible as pale coloured longitudinal lines. The berry bears at its summit the dried remains of the calyx and usually has a short pedicel attached to the base. The taste is very acidic and the odour slightly aromatic. Red currant contains about 2 per cent. of free acid, principally malic and citric acids, about 6 per cent. of invert sugar, red colouring matter, pectin, and about 85 per cent. of water. The ash is about 6 per cent. The juice of the red currant is employed as a flavouring and colouring agent and in the preparation of syrups.

RUBUS IDEUS.—Raspberry is the fresh, ripe fruit of varieties of *Rubus Idæus* Linn. (Fam. Rosaceæ), removed from the fibrous thalamus; it is cultivated in Great Britain. The fruit is a red, hollow, elongated-hemispherical etærio of about 40 to 50 drupels; the etærio is about 10 to 17 millimetres long; each drupel is covered with numerous unicellular, linear trichomes and bears at its apex a style about 4 millimetres long. Raspberry contains about 7 per cent. of invert sugar, citric acid, a red colouring matter, pectin, gum and traces of volatile oil and malic acid. The juice of the raspberry is employed as a flavouring agent.

Preparations

Syrupus Mori, B.P.C.—(Syr. Mori)—Syrup of Mulberry. A solution of sucrose in the juice expressed from mulberry fruit, containing also alcohol (90 per cent.). Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm)

Syrupus Ribis Nigri, B.P.C.—(Syr. Ribis Nig.)—Syrup of Black Currant. A solution of sucrose in the juice expressed from a mixture of black currant with a small proportion of red cherry. Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Syrupus Ribis Rubri, B.P.C.—(Syr. Ribis Rub.)—Syrup of Red Currant. A solution of sucrose in the juice expressed from a mixture of red currant with a small proportion of red cherry. Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

MOSCHUS

(Mosch.)

Musk

Musk is the sac containing the dried secretion from the preputial follicle of *Moschus moschiferus* Linn. (Order Ungulata), a small deer

inhabiting the mountainous regions of Northern India, Central Asia and parts of Siberia. The sac is situated immediately in front of the preputial orifice of the adult animal. In the fresh state the secretion is fluid, but after the animal has been killed the secretion gradually becomes solid, dark reddish-brown and granular. The sacs are cut from the animals, trimmed and dried, and are then known as "pods." They are packed in boxes, caddies or trays, in which they are exported, principally from China.

Musk varies with the district of origin, the most important varieties are Tonquin and Yunnan from China, Cabardine from Siberia and Northern China and Nepal and Assam from the provinces of those names. *Tonquin* musk is considered the best variety; the pods, which contain about 66 per cent. of grain musk, are about 4.5 to 6.5 centimetres in diameter, about 2 centimetres thick, and weigh from 25 to 35 grammes each; they are approximately hemispherical on one side, and almost flat or slightly convex on the other. The hemispherical side, which is covered with the hide of the animal, bears numerous brownish or brownish-white, short hairs surrounding a small, nearly central orifice. The skin of the opposite side is thinner, dark brown, and composed of several thin layers; the outer layers are sometimes removed, leaving only a very thin, steel-blue skin ("blue skin musk"). *Yunnan* musk pods are pear-shaped or nearly spherical. *Cabardine* musk pods are more oval, flatter and more hairy than those of the *Tonquin* variety; they are usually more moist, have a strong, ammoniacal odour, and are of inferior quality. *Nepal* and *Assam* musks are in small spherical pods with longer hairs, and are inferior in quality.

Grain musk (*Moschus in grano*) is the dry, granular secretion from the musk pods. It is a dark-brown, coarsely granular powder, which loses, when dried at 100°, from about 20 to 30 per cent. of its weight, and when dried over sulphuric acid, from about 10 to 15 per cent. of its weight. It yields to alcohol (90 per cent.) from 10 to 20 per cent. of non-volatile extractive, and to water, 50 to 75 per cent. of extractive. The ash contains only a slight trace of iron, and does not exceed about 8 per cent. The odour is strong, very persistent, and characteristic, and the taste is slightly bitter. Grain musk owes its odour to two ketonic bodies, muskone, 0.5 to 2 per cent., and a second ketone which has not yet been investigated. Resin, fat and protein are also present.

Action and Uses.—Grain musk was formerly regarded as a powerful stimulant to the medulla, and good results have been claimed from its use in cases of collapse. There is, however, no evidence to show that it has any action other than that due to its odour. It has been used in the treatment of hysteria, hiccough and other nervous manifestations, also in spasmodic asthma and as a stimulant in typhoid fever, pneumonia and bronchitis; the addition of camphor is an advantage. Grain musk is best **administered** in the form of a cachet, the drug being triturated with lactose; an emulsion may be prepared by

tritulating it with an equal quantity of acacia and sucrose, and adding water, or pills may be made by adding a little acacia and massing with syrup of liquid glucose. Grain musk is sometimes given in the form of tincture (Tinctura Moschi, 1 in 20; dose, $\frac{1}{2}$ to 1 fluid drachm). It is largely used in perfumery as a fixative.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

ARTIFICIAL MUSKS are synthetic, yellowish-white, crystalline compounds, which are now obtainable in a chemically pure state. They are insoluble in water, sparingly soluble (1 to 2 per cent.) in alcohol (95 per cent.), soluble in essential oils, benzyl alcohol, benzyl benzoate and ethyl phthalate. They are stable to caustic alkalis, but discolour when exposed to sunlight. They have very strong and persistent odours somewhat similar to, but distinct from, that of natural musk. Musk xylene is trinitro-*tert.*-butyl-*m*-xylene, $C_6(CH_3)_2(C_4H_9)(NO_2)_3$; it occurs in two crystalline modifications, a stable form, melting-point, 113 to 114°, and a labile form, melting-point, 106°. It may on first melting exhibit an indefinite melting-point owing to the simultaneous presence of the stable and labile forms; if the melted material is allowed to resolidify, the stable modification is produced. Musk ketone is dinitro-*tert.*-butyl-*m*-xylylmethylketone, $C_6(CH_3)_2(C_4H_9)(CO \cdot CH_3)(NO_2)_2$; melting-point, 135° to 136°. Its odour is not as strong as that of musk xylene but has a closer resemblance to that of natural musk. Musk ambrette is dinitro-*tert.*-butyl-*m*-cresyl-methylether, $C_6H(C_4H_9)(CH_3)(O \cdot CH_3)(NO_2)_2$; melting-point, 85°. Its odour is considered to be the finest of all the artificial musks. Other varieties of artificial musk are aldehyde musk, cyano musk and azimido musk, but they are seldom used. Artificial musks are used in perfumery as substitutes for grain musk but are usually regarded as inferior to the natural substance.

MUCUNA

(Mucun.)

Cowhage

Synonym—Cowitch.

Cowhage consists of the hairs which cover the fruit of *Mucuna pruriens* DC. (Fam. Leguminosæ), a climbing plant growing in tropical Africa, India and America.

Cowhage occurs as a loose, yellowish-brown, felted mass of hairs, intermingled with occasional black fragments of the pericarp. The hairs are from 1 to 2.5 millimetres long, unicellular and sharply pointed, with moderately thick, lignified walls, and numerous, minute and often recurved, cuticular prominences. They are about 60 microns in diameter at the base, above which they are slightly constricted, and then widen to about 100 microns at the middle of the hair, finally tapering to an acute apex.

Action and Use.—Cowhage, mixed with honey or treacle, has been employed as a vermifuge.

Dose.—0.6 to 4 grammes (10 to 60 grains).

MYLABRIS

(Mylab.)

Mylabris

Synonyms—Chinese Blistering Beetle; Chinese Cantharides.

Mylabris consists of the dried beetles, *Mylabris sida* Fab. and *M. cichorii* Linn., which are abundant in China and Eastern India, and *M. pustulata* Thunb., which is widely distributed in India (Fam. Meloidæ; Order Coleoptera).

The head is sub-globular, and bears black antennæ with eleven joints, arcuate and enlarged at the end; the mandibles, which have numerous, needle-like teeth on the projecting convex base of the inner surface, are dissimilar, in that the right mandible has a well-developed tooth on the inner margin just behind the tip, whilst the left mandible is without such a tooth; the elytra are black, and are marked by spots and bands, which are orange-yellow or bright red; the remainder of the body is black. *M. sida* is about 15 to 30 millimetres long and 5 to 10 millimetres wide, the yellow bands, as well as the black ground of the elytra, carrying stiff, black hairs; *M. cichorii* is about 12 to 20 millimetres long and 3 to 6 millimetres wide, the yellow bands of the elytra showing a yellow pubescence, while black hairs are present upon the black ground; *M. pustulata* is about 28 millimetres long and 10 millimetres wide, the spots and bands on the elytra being bright red. *Mylabris sida* and *M. cichorii* contain from 1 to 1·2 per cent., and *M. pustulata* up to 2·3 per cent., of cantharidin. The drug also contains fat and an odorous principle. The ash averages about 6·5 per cent., and the volatile matter at 100° about 13·5 per cent.

Action and Uses.—Mylabris is used as a source of cantharidin, and in India and the Eastern Colonies as a substitute for cantharides.

MYRICA

(Myric.)

Bayberry

Synonyms—Wax Myrtle Bark; Bayberry Bark.

Bayberry consists of the dried bark of the root of *Myrica cerifera* Linn. (Fam. Myricaceæ), a shrub growing commonly in the coastal region of North America from New Jersey to Florida. It should be **stored** in air-tight containers and protected from light.

The bark occurs in quilled pieces or curved strips, 2 to 15 centimetres long, 0·5 to 2 centimetres broad, and 1 to 2 millimetres thick; the outer surface is whitish to silvery-grey, except where cork is removed, when it is reddish-brown, smooth or transversely wrinkled, and bears scattered, rounded root-scars; the inner surface is dark brown, and finely striated longitudinally. The fracture is short, granular or

slightly fibrous. A smoothed transverse section is light brown in the outer portion and yellowish-brown in the inner portion, where groups of bast fibres are scattered between the medullary rays. The odour is distinct and aromatic; the taste is slightly bitter and astringent, becoming pungent and acrid.

The diagnostic **microscopical** features are fibres, accompanied by files of rectangular cells containing prismatic crystals of calcium oxalate; groups of stone cells; starch grains, either simple or 2 to 3 compound, individual grains being up to 12 microns in diameter; patches of thick-walled parenchyma, the cells being filled with a yellowish-brown substance, termed "gummy lignin."

Bayberry **contains** a little volatile oil, starch, gum, albumin, a red colouring matter, tannic and gallic acids, and an acrid, astringent resin. It also contains an acidic substance which has been named myricinic acid. It yields to cold water about 15 per cent. of extractive.

Standard.—Bayberry yields not more than 2 per cent. of acid-insoluble ash.

Bayberry, in powder (*Pulvis Myricæ*; *Pulv. Myric.*), contains the constituents and possesses the diagnostic microscopical characters, of *Myrica*, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Bayberry is tonic and astringent, and in large doses it may be emetic. It may be **administered** in the form of infusion or liquid extract. The powdered bark, mixed with ginger, capsicum and clove in varying proportions, is used under the name of composition powder as a domestic remedy for colds and chills.

Dose.—0.6 to 4 grammes (10 to 60 grains).

MYRISTICA

(*Myrist.*)

Nutmeg

Synonyms—*Nux Moschata*; *Myristicæ Semen*.

Nutmeg consists of the dried kernels of the seeds of *Myristica fragrans* Houtt. (Fam. *Myristicaceæ*), a tree indigenous to the Moluccas and cultivated in Penang, Sumatra, the East Indies, etc. The seed is divested of the arillus (mace) and slowly dried, an operation which takes from eight to ten weeks; the testa is then broken and the kernel removed.

The kernels are ovoid in shape, about 2 to 2.5 centimetres long and 1.5 to 2 centimetres broad; the surface is light brown, shows a network of shallow, reticulate grooves, and is marked with numerous small, dark brown points and lines. The hilum is indicated by a slight circular elevation, about 5 millimetres in diameter, somewhat eccentrically placed at the wider end, and connected by a broad, shallow

groove with the chalaza which has the form of a slight circular depression at the opposite end. The kernel consists of a pale brown endosperm covered by a thin, darker-brown perisperm, which penetrates the endosperm by numerous infoldings, producing the characteristic ruminate appearance of the section; the small embryo is found embedded in the endosperm just within the hilum. When pressed by the finger-nail, the cut surface exudes oil. The odour is aromatic and characteristic; the taste is aromatic and somewhat bitter.

The diagnostic **microscopical** characters are the inner, ruminate portion of the perisperm, consisting of an outer brown layer and an inner parenchyma, containing isolated or grouped, yellow oil cells; the polygonal cells of the endosperm, each containing a single aleurone grain with a large crystalloid, about 12 by 20 microns, and starch grains, 2 to 10 compound or simple, the latter being up to about 20 microns in width, all frequently embedded in a dark brown, fatty mass.

Nutmeg **contains** from 5 to 15 per cent. of volatile oil and about 35 per cent. of solid fat. The fatty acids consist mainly of myristic acid (about 61 per cent.), with smaller amounts of palmitic, oleic, linoleic and lauric acids. The ash is about 3 per cent., and the acid-insoluble ash about 0.15 per cent.

Substitutes and Adulterants.—Bombay nutmegs, from *Myristica malabarica* Lam., are longer, narrower and nearly devoid of odour. Macassar or Papua nutmegs, from *M. argentea* Warb., are also longer and narrower and have a uniform, scurfy surface and an acrid taste. Limed nutmegs are nutmegs which have been dipped in milk of lime and subsequently dried, a process which is intended to protect them from the attacks of insects. Factitious nutmegs are sometimes made from damaged nutmegs mixed with clay and pressed into moulds; they yield a small amount of volatile oil and have a high ash.

Standard, B.P.—Nutmeg consists only of the dried kernels of *Myristica fragrans*.

Nutmeg, in powder (*Pulvis Myristicæ* : *Pulv. Myrist.*), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—Nutmeg is aromatic and carminative by virtue of its volatile oil. In large doses, it excites the motor cortex and produces a species of epileptiform convulsions. It is **administered** in the form of powder, or, more usually, as the volatile oil.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

MYROBALANUM

(**Myrobal.**)

Myrobalan

Synonym—Black Chebulic Myrobalans.

Myrobalan consists of the dried, immature fruits of *Terminalia Chebula* Retz. (Fam. Combretaceæ), a tree indigenous to India.

The fruits are black in colour, ovoid or fusiform in shape, about 10 to 30 millimetres long and 5 to 15 millimetres wide. They are much shrivelled longitudinally, hard and brittle; the fractured surface is shiny, and when broken, the fruits often show a central cavity. The drug is without odour but has a very astringent taste. It **contains** from 20 to 40 per cent. of tannin and a greenish oleoresin.

Substitute.—The mature fruits, which are commonly imported for use in various technical processes, are larger and yellowish-brown in colour.

Action and Uses.—Myrobalan is used as an equivalent of gall in India and the Eastern Colonies. Unguentum Myrobalani and Unguentum Myrobalani cum Opio correspond to Unguentum Gallæ and Unguentum Gallæ cum Opio, but are prepared with myrobalan instead of gall. The mature fruit is employed extensively for tanning.

MYRRHA

(Myrrh.)

Myrrh

Myrrh is an oleo-gum-resin obtained from the stem of *Commiphora molmol* Engl. and possibly other species of *Commiphora* (Fam. Burseraceæ), shrubs or small trees growing in North-Eastern Africa and Southern Arabia. The oleo-gum-resin is secreted in numerous schizogenous ducts, which form lysigenous cavities by the breaking down of intervening tissue and become filled with the secretion. This is obtained by wounding the bark, or is exuded through natural fissures. It is yellowish-white and fluid at first, but soon hardens to a reddish-brown mass. It is exported from the coast of Somaliland.

Myrrh occurs in rounded or irregular tears, or in masses of agglutinated tears. Externally, it is reddish-brown or reddish-yellow in colour, dry, and often covered with a fine dust. It breaks with a brittle fracture, exhibiting a granular, somewhat translucent surface, which is oily and of a rich brown colour, and frequently exhibits whitish spots or veins. Myrrh may be identified by triturating it with five times its weight of sand, and shaking the resulting powder with ether; when the filtered ethereal solution is allowed to evaporate from a porcelain dish so as to leave a thin film, a violet colour is produced when the film is exposed to bromine vapour. The drug has an agreeable, aromatic odour, and an aromatic, bitter and acrid taste.

Myrrh **contains** 25 to 40 per cent. of resin, 57 to 61 per cent. of gum, 2.5 to 8 per cent. of volatile oil, a bitter principle, and 3 to 4 per cent. of impurities. That portion of the resin which is soluble in ether contains three free resin acids, namely, α -, β - and γ -commiphoric acids, the esters of a resin acid, commiphorinic acid and two phenolic resins, α - and β -heerabomyrrhol. From the resin insoluble in ether, two other acids, α - and β -heerabomyrrholic acids, have

been obtained. These constituents show little analogy with the substances that have been isolated from other resins. The volatile oil is yellow, and rapidly resinifies when exposed to the air, producing resin similar to that contained in the myrrh itself; it contains eugenol, *m*-cresol, cuminaldehyde, free formic and acetic acids, myrrholic acid (an isomeride of α -commiphoric acid) in the form of an ester, and the sesquiterpene, heerabolene. Both volatile oil and resin yield the same characteristic violet reaction with bromine vapour. The gum is apparently allied to acacia and, like it, is associated with an oxidase.

Substitutes and Adulterants.—Fahdlī or Arabian myrrh occurs in small masses of agglutinated tears with a less dusty surface and free from whitish markings on the fractured surface. It is less bitter in taste and also less fragrant than genuine Somali myrrh. Yemen myrrh occurs in large dusty pieces. It does not exhibit whitish streaks and does not exude oil when pressed with the finger-nail, and is less aromatic than myrrh. Perfumed bdellium or bissabol closely resembles myrrh. It breaks with a waxy fracture and gives an oily exudate when pressed with the finger-nail. The whitish markings on the fractured surface are traversed by brown resin patches. It differs from myrrh both in odour and taste and does not respond to the colour test; it is probably obtained from *C. erythraea* var. *glabrescens* Engl. Opaque bdellium is a very hard, yellowish-brown, opaque gum-resin with a slight odour and a bitter taste. African bdellium occurs in hard pieces, translucent in thin layers and breaking with a dull slaty fracture; it has a bitter taste and an odour recalling that of pepper. Indian bdellium occurs in irregular, reddish-brown masses. The fractured surface is hard and, like the outer surface, covered with minute, shiny points of resin. It has a feebly cedar-like odour which is developed on keeping and an acid but not bitter taste. Gum hotai occurs in liver-coloured, opaque masses. It contains an acid resin and a saponin, and is used for washing the hair. Finely powdered myrrh does not represent the official drug; it is deficient in volatile oil and may yield as much as 13 per cent. of ash.

Standard, B.P.—Myrrh contains not more than 4 per cent. of foreign organic matter. Ash, not more than 9 per cent. Matter insoluble in alcohol (90 per cent.), not more than 70 per cent.

Action and Uses.—Myrrh is mildly disinfectant, and is a local stimulant to the mucous membranes. Internally, like the other resins, it is carminative and, during excretion, acts as a mild, stimulating expectorant, diaphoretic and diuretic. Tincture of myrrh and tincture of myrrh with borax are used for mouth-washes and gargles in ulcerated or relaxed throat, aphthous stomatitis and spongy gums.

Dose.—0·3 to 1 gramme (5 to 15 grains).

Preparations

Pilulæ Aloes et Myrrhæ, B.P.C.—(Pil. Aloes et Myrrh.)—Aloes and Myrrh Pills. *Syn.*—Pilulæ Rufi; Rufus Pills. Each pill contains 2 grains of aloes and 1 grain of myrrh. Dose.—1 or 2 pills.

The mass with which these pills are made was included in the British Pharmacopæia, 1914.

Tinctura Aloes et Myrrhæ, B.P.C.—(Tinct. Aloes et Myrrh.)—Tincture of Aloes and Myrrh. *Syn.*—Elixir Proprietatis. Aloes, 1 in 10, and saffron, in tincture of myrrh. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Tinctura Myrrhæ, B.P.—(Tinct. Myrrh.)—Tincture of Myrrh. 1 in 5, by maceration with alcohol (90 per cent.). Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tinctura Myrrhæ Composita, B.P.C.—(Tinct. Myrrh. Co.)—Compound Tincture of Myrrh. *Syn.*—Tinctura Myrrhæ et Aloes. Myrrh and aloes, of each about 1 in 20.

Tinctura Myrrhæ et Boracis, B.P.C.—(Tinct. Myrrh. et Borac.)—Tincture of Myrrh and Borax. Tincture of myrrh, about 1 in 3, with tincture of *krameria*, oils of bergamot, lemon, orange, neroli and rosemary, and borax.

NAPHTHALENI TETRACHLORIDUM

(Naphthalen. Tetrachlor.)

Naphthalene Tetrachloride

Naphthalene tetrachloride is the addition product of naphthalene prepared by the action of chlorine on naphthalene until absorption is complete. The mixture of chlorinated compounds is extracted successively with light petroleum and alcohol, and the residue is crystallised from chloroform. It forms a white, odourless, crystalline powder.

Insoluble in water; slightly soluble in alcohol and ether; more soluble in chloroform.

Standard.—Naphthalene tetrachloride melts between 185° and 187°. Ash, not more than 0.1 per cent.

Action and Uses.—Naphthalene tetrachloride is administered in cachets, capsules, or pills for the same purposes as naphthalene.

Dose.—0.2 to 0.8 gramme (3 to 12 grains).

NAPHTHALENUM

(Naphthalen.)

Naphthalene

Naphthalene is a hydrocarbon obtained by the fractional distillation of coal tar; it is present in large quantity in the fraction obtained between 170° and 230°, from which on cooling it separates in crystals. These crystals are freed from liquid by straining and pressing, washed successively with caustic soda solution and sulphuric acid, and finally purified by sublimation. It occurs in colourless, transparent, crystalline or micaceous scales, having a characteristic, tar-like odour, and a sharp, aromatic taste. Specific gravity, about 1.15; boiling-point, about 218°. It volatilises slowly on exposure to the air, and rapidly when heated, and sublimes much below its melting-point. It burns with a smoky, luminous flame.

Insoluble in water; soluble in alcohol (1 in 23), ether (1 in 3) and chloroform (1 in 1.5).

Standard.—Naphthalene melts between 79° and 80° . Ash, not more than 0.05 per cent. A 2 per cent. w/v alcoholic solution is neutral to litmus. 1 gramme heated with sulphuric acid yields a solution with not more than a faint pink colour. When 1 gramme is boiled with 1 millilitre of sodium hydroxide solution and 10 millilitres of water, and the filtrate acidified with hydrochloric acid, no colour is formed on adding 1 drop of ferric chloride solution (absence of phenolic bodies).

Action and Uses.—Naphthalene has been employed as an antiseptic, but some doubt has been expressed as to whether it has itself such properties, or whether its antiseptic effects are due to the formation of naphthols. Its action closely resembles that of the naphthols, which are generally employed in preference. Naphthalene has been used as an intestinal disinfectant and in the treatment of diarrhœa. It is a vermifuge for both tape- and round-worms. Its toxicity is low because very little is absorbed. Large doses are liable to produce a form of parenchymatous nephritis. Externally, it is used in the form of an ointment (10 per cent.), and a solution of a similar strength in olive oil is used as a parasiticide in scabies and to destroy pediculi. Naphthalene is best **administered** in cachets or capsules. It is also prepared in the form of balls and tablets for keeping away moths from articles of clothing.

Dose.—0.2 to 0.8 gramme (3 to 12 grains).

ETHYLIS PHTHALAS.—Ethyl phthalate, $C_6H_4(COOC_2H_5)_2$, or diethyl phthalate, is a colourless, odourless liquid, having a specific gravity of about 1.12 and a boiling-range of 290° to 300° . It is miscible with oils and aromatic hydrocarbons, partly miscible with petroleum, and immiscible with water. It is used as a solvent and plasticiser in the manufacture of lacquers and varnishes, and also as a denaturant for alcohol.

AMYLIS PHTHALAS.—Amyl phthalate, $C_6H_4(COOC_5H_{11})_2$, may be obtained by the esterification of amyl alcohol with phthalic acid and occurs as an almost colourless and odourless liquid, having a specific gravity of about 1.026 and a boiling-range of 336° to 342° . It is miscible with oils and hydrocarbons but not with water, and is used as a solvent in the manufacture of lacquers and varnishes.

BUTYLIS PHTHALAS.—Butyl phthalate, $C_6H_4(COOC_4H_9)_2$, is prepared by the action of butyl alcohol on phthalic anhydride. It has a specific gravity of about 1.05 and boils at about 325° . It is immiscible with water, but mixes readily with oils and hydrocarbons, and is used extensively as a plasticiser and solvent in the manufacture of lacquers and varnishes.

NARCOTINA

(Narcotin.)

Narcotine

Narcotine, $C_{19}H_{14}O_4N(OCH_3)_3$, is an alkaloid obtained from opium,

in which it exists to the extent of from 2 to 10 per cent., for the most part in the free state. It may be obtained directly from opium by extraction with ether, or by digesting with dilute hydrochloric acid the residue left after exhausting opium with water; this solution is precipitated with sodium carbonate, the precipitate obtained boiled with alcohol, and the alcoholic solution concentrated and allowed to crystallise. It occurs in the form of colourless, odourless, tasteless, shining, rhombic prisms, or long needles. Its acid solutions taste bitter and are dextrorotatory; solutions in alcohol or chloroform are lævorotatory. In concentrated sulphuric acid, the alkaloid dissolves, forming a greenish-yellow solution which, on warming, becomes red, and on boiling, violet. Nitric acid produces a yellow-coloured solution. Sulphuric acid containing a trace of nitric acid produces a blood-red colour. The alkaloid, dissolved in dilute mineral acid, is almost completely precipitated by the addition of excess of sodium acetate.

Insoluble in water; soluble in ether, boiling alcohol, ethyl acetate and chloroform; soluble to some extent in benzene (distinction from morphine, which is quite insoluble); soluble in dilute mineral acids; insoluble in cold, but soluble in boiling solutions of alkalis.

Standard.—Narcotine melts between 175° and 176° . Ash, not more than 0.1 per cent.

Action and Uses.—Narcotine has at first a mildly depressant action upon the cerebral hemispheres. Its effect is similar to that of morphine on the sensory cells but is much less marked; this action is followed by exaggerated reflexes due to stimulation of the spinal cord, resulting in restlessness and tremors. Like papaverine, it relaxes the tone of plain muscle, especially when this is tonically contracted. It is much less poisonous than either morphine or codeine.

Dose.—0.06 to 0.2 gramme (1 to 3 grains).

NEOARSPHENAMINA

(Neoarsphenamin.)

Neoarsphenamine

Synonyms—Novarsenobenzol; Novarsenobenzene.

Neoarsphenamine consists mainly of sodium 3 : 3'-diamino-4 : 4'-dihydroxyarsenobenzene - N - methylenesulphoxylate, $(\text{NH}_2)(\text{OH})\text{C}_6\text{H}_3\text{As} : \text{AsC}_6\text{H}_3(\text{OH})(\text{NH}\cdot\text{CH}_2\cdot\text{O}\cdot\text{SO Na})$. This compound is the sodium salt of an acid differing from the principal constituent of arsphenamine in the replacement of one hydrogen atom of an amino-group by a methylenesulphinic group, the replacement being effected by treatment with sodium formaldehydesulphoxylate.

Neoarsphenamine occurs as a dry, yellow powder, freely mobile in contact with glass surfaces, and without odour except that due to traces of ether or alcohol. It is distributed in sealed glass phials from which the air has been evacuated or replaced by an inert gas. It contains, when determined by an approved method, not less than 18 per cent. and not more than 21 per cent. of As. The proportion of arsenic may be determined by the method given under Sodii Aminarsonas. The aqueous solution is neutral or slightly alkaline to litmus, and decolourises solution of iodine. On the addition of hydrochloric acid to the aqueous solution, a yellow precipitate of the free acid is produced, and when the mixture is warmed, sulphur dioxide is evolved and gives a blue colour with starch-iodate paper. When 10 millilitres of a 2 per cent. w/v aqueous solution acidified with phosphoric acid is distilled until about 5 millilitres of distillate has been collected, the distillate contains formaldehyde, which may be detected by adding 5 drops of a 1 per cent. w/v aqueous solution of phenol and running a layer of sulphuric acid under the mixture, when a red ring is produced at the zone of contact. Neoarsphenamine should be **stored** at a temperature below 15°. If it has become darker in colour it should not be used.

Soluble in water; insoluble in dehydrated alcohol and ether.

Standard, B.P.—Neoarsphenamine is controlled by regulations made under the Therapeutic Substances Act, 1925. The standard preparation for Great Britain and Northern Ireland is a quantity of neoarsphenamine kept in the National Institute for Medical Research, London. It complies with biological tests, carried out in an institution or laboratory approved by the licensing authority, for maximum toxicity and therapeutic potency. When 0.6 gramme of the powder is added to 1 millilitre of distilled water, it dissolves rapidly and completely, yielding a clear, yellow solution free from suspended particles. No precipitate is produced on shaking a 10 per cent. w/v aqueous solution with an equal volume of N/1 sodium carbonate (absence of arsphenamine). When kept in sealed phials, at a temperature of 56° for not less than twenty-four hours, the product retains its colour, physical properties and solubility.

Action and Uses.—Neoarsphenamine is the most efficient derivative of arsphenamine. It has the advantages of being less toxic, more readily soluble, and of not requiring to be neutralised. On the other hand, it is less active therapeutically. Neoarsphenamine is now used almost to the exclusion of arsphenamine. In general, the treatment **administered** to a case of early syphilis consists of a number of courses of intravenous injections of neoarsphenamine in conjunction with mercury or bismuth preparations, which may be given at the same time or in the intervals between arsenical courses. In each course the single dose of neoarsphenamine for a man of average weight, and presenting no contra-indication, increases from 0.45 to 0.75 gramme (7 to 12 grains). A dose of 0.45 gramme (7 grains) should cause *Sp. pallida* to disappear from the secretion of chancres or early secondary lesions in twenty-four hours. The number of injections per course varies from seven to ten, and the

intervals between courses from six weeks to two or three months. The number of courses is three or more, depending largely on the effect on the Wassermann and other serum reactions. If these are negative at the end of the first course, two or three more courses may be considered sufficient. If the serum reactions persist, the treatment is prolonged considerably. After the treatment has been completed, the patient is kept under observation for a minimum period of two years, during which time the blood is tested periodically, and the cerebrospinal fluid once or more often. When, for any reason, intravenous injections are impracticable, and sometimes as a matter of preference in the first instance, the arsphenamine preparation is given intramuscularly or into the areolar tissue overlying the muscle fascia in the gluteal region. In this case the preparation of choice is sulpharsphenamine, which causes far less discomfort than does neoarsphenamine administered by this route. Sometimes silver arsphenamine is still given to early cases, but usually it is reserved for syphilis of the central nervous system.

In cases with infections of longer standing, the serum reactions are not influenced, and some syphilologists content themselves with giving one or two courses, after which they place the patient under surveillance. Others persist in treatment for a number of years on the principle that the positive reactions mean living *Sp. pallida* somewhere in the body, and that the persistent treatment is an insurance against their causing damage to vital structures. In late syphilis of the nervous system, especially in tabes and general paresis, although the arsphenamines are greatly used, and especially perhaps sulpharsphenamine and silver arsphenamine, greater reliance is placed on tryparsone, which is given in courses of ten or more weekly injections, each of 2 to 3 grammes (30 to 45 grains), often in conjunction with injections of bismuth (see Tryparsonum). If this fails, it is usual to inoculate with malaria or recurrent fever, or to produce a series of pyrexial paroxysms by injections of such agents as sulphur in oil or Vaccinum Typho-paratyphosum. The pyrexial method has revolutionised the treatment of general paresis, completely altering the outlook in this hitherto hopeless form of syphilis. There is no evidence pathologically that a syphilitic patient ever becomes free from spirochaetes.

Solutions of neoarsphenamine for intravenous use are prepared by dissolving up to 0.3 gramme (5 grains) in 5 millilitres (75 minims) of cold sterilised water, or larger doses in 10 millilitres (150 minims). Intramuscular injections are painful, but the pain may be reduced by dissolving the neoarsphenamine in guaiacol-dextrose solution (guaiacol 1 part, dextrose, 50 parts, recently sterilised water, to 100 parts), but for this route sulpharsphenamine is preferred. Shortly after the introduction of the arsphenamines in the treatment of syphilis, toxic manifestations were observed. So various have been these ill-effects that no thoroughly satisfactory method of classification is possible. The following constitute the majority of recorded disturbances: (1) Immediate reactions, for example diarrhoea, vomiting, pyrexia, headache, and the vasomotor or so-called anaphylactoid effects. (2) Effects involving

the nervous system, "encephalitis hæmorrhagica." (3) Effects involving the liver: clinically these may be grouped as: (a) early jaundice, usually mild and evanescent; (b) late jaundice, sometimes occurring several weeks after the end of a course of treatment; (c) acute yellow atrophy. (4) Exfoliative dermatitis. (5) Various rare lesions, acute hæmorrhagic nephritis, purpura hæmorrhagica, aplastic anæmia. (6) Complications now regarded as relapses of the disease, or as due to temporary stimulation of the activity of the spirochætes. The first of these include such affections of the nervous system as cranial nerve palsies. In addition, accidents may occur due to faulty injection, such as perivascular infiltration and necrosis at the site of injection, thrombosis, or phlebitis.

In the prophylaxis of the toxic effects the following precautions should be taken. The general health of the patient should be studied; cachexia, diabetes, nephritis and cardiac lesions call for increased caution. The patient must be carefully prepared, the bowels should be opened, and no food taken for two hours before injection. A full diet containing sufficient protein and fat appears to be the best from the point of view of preventing damage to the liver. In the actual treatment of toxic manifestations, adrenaline or ephedrine is given for the immediate reactions, whilst sodium thiosulphate is administered subcutaneously or intravenously for the later complications, especially dermatitis. There is strong evidence that in dermatoses resulting from treatment with preparations of arsphenamine liver extract is curative. This is based on the view that liver disturbance is at the root of the skin trouble. Intravenous injection of 25 millilitres (375 minims) of 20 per cent. w/v solution of dextrose on alternate days is also recommended. Neoarsphenamine has been used in the treatment of a large number of diseases. It is of value in septicæmia, malaria, relapsing fever, rat-bite fever, Vincent's angina (local application) and yaws. Neoarsphenamine which has become darker in colour should not be used. Solutions for **injection** may be prepared by dissolving the contents of a sealed container in the required quantity of sterile, freshly-distilled water, and used immediately.

Dose.—0.15 to 0.9 gramme ($2\frac{1}{2}$ to 14 grains), by intravenous injection.

NICOTINA

(Nicotin.)

Nicotine

Nicotine is a liquid alkaloid which exists chiefly as malate in the leaves of *Nicotiana Tabacum* Linn. (Fam. Solanaceæ), the dried

Virginian leaf sometimes containing as much as 7 per cent. It may be obtained by digesting the leaves in acidified water, evaporating to a small bulk, distilling with excess of potassium hydroxide, shaking the distillate with ether, distilling the ethereal solution, and placing the residual nicotine in contact with quicklime to remove water, and finally distilling it in a current of hydrogen. It occurs as a very hydroscopic, colourless or yellowish oily liquid, having an unpleasant, pungent and acrid odour of stale, burnt tobacco. It gradually becomes brown in contact with the air, and is inflammable. In very dilute, aqueous solution it has a sharp, burning and persistent taste. The free base is lævorotatory, the salts dextrorotatory. Its aqueous solution is alkaline and turns red litmus blue, but does not redden phenolphthalein. It remains liquid at -10° , and volatilises readily and without decomposition in a current of steam. Potassium hydroxide separates it from its aqueous solution. Chlorine colours it brown to blood-red. It is precipitated by most of the usual alkaloidal reagents. Oxidation with chromic acid mixture yields nicotinic acid, and this, when distilled with lime, yields pyridine. In the absence of any other free base, nicotine can be determined by titration with standard acid, using solution of litmus as indicator. Pure nicotine boils at about 240° to 246° , and has a specific gravity of about 1.01 at 20° . Optical rotation at 20° , 159° to 168° . Refractive index at 20° , about 1.52.

Freely **soluble** in water, alcohol, ether, light petroleum, terpenes and fixed oils.

Action and Uses.—Nicotine first stimulates nerve cells and then paralyzes them. It, therefore, at first raises blood pressure and later diminishes it. The paralyzing action also results in a quicker heart, dilated bronchioles, and more active peristalsis, the latter from depression of the inhibitory fibres of the sympathetic. Nicotine is not used in medicine. Preparations of nicotine are largely employed in horticulture as insecticides, usually by spray or vaporisation; sprays suitable for general use may contain 1 part of crude nicotine with 10 to 20 parts of soft soap in 2000 parts of water. In using them, precautions should be taken against absorption by contact with the skin. It is an extremely poisonous substance, and large doses may prove fatal within a few minutes, the symptoms being those of sudden paralysis of the central nervous system, including the respiratory centre. In cases of **poisoning** by nicotine, the stomach should be evacuated, and repeated doses of tannic acid given. The patient must be kept warm in bed, and the medulla kept active by such stimulants as caffeine, atropine and strychnine; but if there are signs of respiratory failure, artificial respiration with oxygen must be resorted to immediately.

NICOTINÆ SALICYLAS.—Nicotine salicylate has been used in 0.1 per cent. solution or ointment as a parasiticide, particularly in scabies.

NICOTINÆ SULPHAS.—Nicotine sulphate has been given by injection in post-encephalitic conditions, in doses of 0.001 gramme ($\frac{1}{1000}$ grain).

NITROBENZENUM

(Nitrobenz.)

Nitrobenzene*Synonym*—Oil of Mirbane.

Nitrobenzene, $\text{C}_6\text{H}_5\text{NO}_2$, may be prepared by treating benzene with a mixture of nitric and sulphuric acids, first at a temperature of 25° to 30° and finally at 70° to 90° , washing the product with weak solution of alkali, and distilling in a current of steam. It occurs as a pale yellow, highly refractive oily liquid, having a very sweet taste and an odour of bitter almond. It solidifies at a low temperature to acicular crystals melting at about 5° , and readily volatilises with steam. It distils between 209° and 211° . Specific gravity, about 1.21. It is reduced by acid reducing agents to aniline; by alkaline agents to azoxy-, azo-, and hydrazobenzene; by neutral agents to nitrosobenzene and phenylhydroxylamine.

Almost **insoluble** in water; miscible with alcohol, ether and benzene

Action and Uses.—Nitrobenzene is a powerful poison, causing great muscular weakness, a cyanotic colour of the skin, and rapid paralysis of the respiratory centre. These effects are due in part to methæmoglobin formation, and in part to central nervous action. The fumes of nitrobenzene must not be inhaled, neither must the pure substance be allowed to come in contact with the skin. It is not used in medicine, but is largely employed as an intermediate in the synthesis of benzene derivatives, and as an insect repellent. In cases of **poisoning**, the stomach should be evacuated, cerebral stimulants given internally, and strychnine injected hypodermically; artificial respiration must be employed, if necessary. In those engaged in trades in which nitrobenzene is used, it is extremely difficult to determine the early stages of poisoning, since it is not possible to detect methæmoglobin until from 5 to 10 per cent. is present in the blood.

NITROGENII MONOXIDUM

(Nitrogen. Monox.)

Nitrous Oxide

Nitrous oxide may be prepared by heating ammonium nitrate, and is supplied compressed in metal cylinders. It occurs as a colourless gas, with a characteristic odour and a faintly sweetish taste; it is heavier than air. It supports combustion, and a glowing splinter of wood inflames on being plunged into the gas. The gas may be distinguished from oxygen by the absence of red fumes on mixing it with nitric oxide. Nitrous oxide is sometimes known as "laughing gas."

Soluble in water (about 1 in 2 by volume, between 15° and 25°).

Standard, B.P.—Nitrous oxide, drawn from a cylinder in the upright position, contains not less than 93 per cent. v/v of N_2O . Carbon monoxide limit, determined on the first portion of gas drawn from a cylinder in the upright position, 50 parts per million v/v. It complies also with tests for the absence of halides and sulphuretted hydrogen, and of arseniuretted hydrogen and phosphoretted hydrogen, and with limit tests for water vapour and carbon dioxide, uncondensable gases, acidity or alkalinity, reducing substances and oxidising substances.

Action and Uses.—Nitrous oxide, administered from an inhaler in the absence of oxygen or air, rapidly enters into the circulation, is absorbed by the plasma, and produces partial asphyxia. The gas acts in two ways; it causes asphyxia, and progressively paralyses the nerve centres, acting as a general anæsthetic. During inhalation of a mixture of nitrous oxide and air, the first stage is marked by subjective sensations followed by loss of control. This stage is succeeded by drowsiness and diminished sensation to pain, and finally complete anæsthesia. Nitrous oxide is the safest anæsthetic known when prolonged anæsthesia is not required. The disadvantage of its use alone is that lack of oxygen produces a sudden rise of blood pressure which may be dangerous. If oxygen is inhaled with nitrous oxide, the asphyxial symptoms are eliminated, but very profound anæsthesia cannot always be obtained without increasing the pressure at which the gases are absorbed or without the previous administration of hypnotics, such as morphine and hyoscine or barbituric acid derivatives. It is employed by inhalation as a general anæsthetic, particularly in dental practice. It is frequently administered to produce a light anæsthesia before the administration of ether, for general anæsthesia in conjunction with oxygen, and sometimes as a vehicle for ether.

NOVAURANTIA

(Novaurant.)

Orange G

Orange G (Colour Index No. 27) is the disodium salt of benzeneazo- β -naphthol-6 : 8-disulphonic acid, and may be prepared by coupling benzenediazonium chloride with β -naphthol-6 : 8-disulphonic acid and converting the product into the disodium salt. It occurs as a yellowish-red powder or in crystalline leaflets. The colour of the aqueous solution is unaltered on the addition of hydrochloric acid, but becomes yellowish-red on the addition of alkali. Calcium chloride precipitates a crystalline calcium salt, which is readily soluble in hot water but sparingly soluble in cold.

Soluble in water, giving an orange-yellow solution; readily soluble in alcohol.

Standard.—Orange G leaves not less than 36 per cent. and not more than 50 per cent. of sulphated ash. Arsenic limit, 10 parts per million. Lead limit, 50 parts per million. Dissolve the sulphated ash from 1 gramme in 20 millilitres of dilute hydrochloric acid, and add 1 millilitre of potassium ferrocyanide solution; no precipitate is obtained (limit of zinc).

Action and Uses.—Orange G is unaffected by acids and alkalis, or by light, and is a useful orange colouring agent for medicines and foodstuffs. In combination with tartrazine, as in *Liquor Tartrazinæ Compositus*, it forms a useful substitute for the colouring matter of saffron. The addition of 5 minims of *Liquor Tartrazinæ Compositus* to each fluid ounce of a colourless liquid imparts a stable, saffron-like colour, equivalent to that produced by 25 minims of glycerin of saffron, or 12½ minims of freshly prepared tincture of saffron. Orange G is also used as a microscopical stain.

Preparation

Liquor Tartrazinæ Compositus, B.P.C.—(*Liq. Tartrazin. Co.*)—Compound Solution of Tartrazine. *Syn.*—*Liquor Flavus*. Tartrazine, 0.75 per cent. w/v, and orange G, 0.25 per cent. w/v, in glycerin and chloroform water.

NUX VOMICA

(*Nux Vom.*)

Nux Vomica

Synonym—*Strychni semen* I.A.

Nux vomica consists of the dried ripe seeds of *Strychnos Nuxvomica* Linn. (Fam. Loganiacæ), a small tree widely distributed over India and the Malay Archipelago. The ripe fruit, which externally resembles an orange, contains a whitish, bitter pulp in which are embedded from three to five seeds; the seeds are removed when ripe, washed free from pulp, and dried in the sun.

The seeds are disc-shaped, about 10 to 30 millimetres in diameter and 4 to 6 millimetres thick, hard, usually flat but sometimes irregularly curved, and the edge is rounded or sub-acute. The testa is grey to greenish-grey externally, and possesses a satiny sheen due to the presence of a dense covering of closely appressed hairs radiating from the centre of each flat face. The micropyle is situated on a prominence on the edge, and from it a radial ridge extends to the centrally-placed hilum. The abundant endosperm is horny and translucent, and exhibits a central, thin, disc-shaped hollow in which lie two small, cordate, leafy cotyledons attached to a cylindrical radicle. The drug is odourless, and has an extremely bitter taste.

The diagnostic **microscopical** characters are the epidermal trichomes, having strongly-thickened, pitted and lignified bases and cylindrical limbs up to about 1 millimetre long, and each strengthened by several narrow, longitudinal, lignified ribs, which break up in the powder into small, structureless, rod-like fragments; the colourless, thick-walled, unligified, polygonal cells of the endosperm, containing an oil-plasma with a few aleurone grains, and exhibiting a well-marked plasmodesma; the absence of starch and crystals of calcium oxalate.

Nux vomica **contains** the alkaloids, strychnine and brucine, together with traces of strychnicine and vomicine and of a glycoside, loganin. It also contains fatty matter (about 3 per cent.), caffeeo-tannic acid, and a trace of copper. The total alkaloid present varies from 1·8 to 5·3 per cent. Of this total alkaloid about one-half is strychnine, although this proportion is subject to some variation. The pulp of *nux vomica* fruit contains about 5 per cent. of loganin, together with strychnicine.

Substitutes.—The seeds of *S. nux-blanda* Hill and those of *S. potatorum* Linn. have been imported as *nux vomica*; the former closely resemble the official seeds, but may be distinguished by their paler colour, the presence of a distinct ridge on the edge of the seed and the absence of a bitter taste; they contain no strychnine or brucine. The seeds of *S. potatorum* are smaller, thicker and also free from bitterness.

Standard, B.P.—*Nux vomica* contains not less than 1·2 per cent. of strychnine and not more than 1 per cent. of foreign organic matter.

Nux vomica, in powder, contains the constituents and possesses the diagnostic microscopical characters of *Nux Vomica*, and complies with the limit for strychnine of the unground drug. When powdered *nux vomica* is prescribed, the standardised powder, *Nux Vomica Pulverata*, must be used.

Action and Uses.—The properties of *nux vomica* are virtually those of the alkaloid strychnine (see *Strychnina*). Powdered *nux vomica* is employed in atonic dyspepsia and is **administered** in cachets or capsules, often with bismuth compounds or pepsin. The preparations in common use are the tincture and the dry extract; the tincture is employed in mixtures for its stimulant action on the gastro-intestinal tract. In the mouth, it acts as a bitter, increasing the appetite. In the intestine, it stimulates peristalsis, and is often combined with laxatives, such as *cascara sagrada*, in chronic constipation due to atony of the bowel. Dry extract of *nux vomica* is used in pills, in association with purgatives and with ferruginous preparations, in anæmia. In cases of **poisoning** by *nux vomica*, the antidotes described under *Strychnina* should be employed.

Preparations

Extractum Nucis Vomice Liquidum, B.P.—(Ext. Nuc. Vom. Liq.)—Liquid Extract of *Nux Vomica*. It is prepared with alcohol (70 per cent.), detatted, and adjusted with alcohol (45 per cent.) to contain 1·5 per cent. w/v of strychnine (limts, 1·425 to 1·575); 0·2 millilitre contains 0·003 grammic, and 3 minims contains about $\frac{1}{2}$ grain, of strychnine. The final alcohol content is about 40 per cent. Dose.—0·06 to 0·2 millilitre (1 to 3 minims).

Extractum Nucis Vomicae Siccum, B.P.—(Ext. Nuc. Vom. Sicc.)—Dry Extract of Nux Vomica. It is prepared with alcohol (70 per cent.), the percolate being defatted and evaporated to dryness. It is adjusted with calcium phosphate to contain 5 per cent. of strychnine (limits, 4.75 to 5.25); 0.06 gramme contains 0.003 gramme, and 1 grain contains about $\frac{1}{20}$ grain, of strychnine. It should be stored in small, wide-mouthed, well-closed containers in a cool place. Dose.—0.015 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

Extractum Strychni I.A. is a defatted extract prepared with alcohol (70 per cent.) and contains 16 per cent. of total alkaloids.

Nux Vomica Pulverata, B.P.—(Nux. Vom. Pulverat.)—Powdered Nux Vomica. *Syn*—Pulvis Nucis Vomicae. Nux vomica in fine powder adjusted with powdered nux vomica of different alkaloidal content, or with lactose, to contain 1.2 per cent. of strychnine (limits, 1.14 to 1.26). 0.25 gramme contains 0.003 gramme, and 4 grains contains about $\frac{1}{20}$ grain, of strychnine. Ash, not more than 3 per cent. Dose.—0.06 to 0.25 gramme (1 to 4 grains).

Pulvis Strychni I.A. contains 2.5 per cent. of total alkaloids.

Pilulae Aloes et Nucis Vomicae, B.P.C.—(Pil. Aloes et Nuc. Vom.)—Aloes and Nux Vomica Pills. Each pill contains 2 grains of aloes, $\frac{1}{4}$ grain of dry extract of nux vomica and $\frac{1}{4}$ grain of dry extract of belladonna. Dose.—1 pill.

Tinctura Nucis Vomicae, B.P.—(Tinct. Nuc. Vom.)—Tincture of Nux Vomica. Liquid extract of nux vomica, 8.34 per cent. v/v, with alcohol (90 per cent.) and distilled water. It contains 0.125 per cent. w/v of strychnine (limits, 0.119 to 0.131); 2 millilitres contains 0.0025 gramme, and 30 minims contains about $\frac{1}{20}$ grain, of strychnine. Dose.—0.6 to 2 millilitres (10 to 30 minims).

Tinctura Strychni I.A. is prepared with alcohol (70 per cent.) and contains 0.25 per cent. of total alkaloids.

OESTRINUM

(Oestrin.)

Oestrin

Oestrin is a generic term applied to hormones, present in the ovaries and certain other tissues of animals, which have the property of producing those changes in the genital organs of female animals characteristic of the oestrus cycle, and can also produce these changes in the animal after removal of the ovaries. They may be obtained from placenta and from the urine of stallions, pregnant mares and pregnant women.

Oestrins are identified by their power of transforming the vaginal epithelium of ovariectomised rats or mice from the dioestrus to the oestrus form within forty-eight hours of injection under the skin of the animal. They are excreted in small amounts in normal urine, but in much larger quantities during pregnancy. At least two distinct oestrus-producing substances are present in human pregnancy urine, a hydroxyketone, 3-hydroxy-17-keto-1 : 3 : 5-oestratriene, $C_{18}H_{22}O_2$, called ketohydroxyoestrin, oestrone, or the "follicular hormone," and a triol, 3 : 16 : 17-trihydroxy-1 : 3 : 5-oestratriene, $C_{18}H_{24}O_3$, called trihydroxyoestrin, oestriol, or the "follicular hormone hydrate." Ketohydroxyoestrin occurs in the form of colourless crystals which

melt at about 254° to 257°, and the solution is dextrorotatory. It yields a monomethyl derivative which melts at about 165°, and a monoacetate melting at about 125°. Trihydroxyoestrin melts at about 279°, the triacetate at 126°, and the monomethylether at about 165°. On adding concentrated sulphuric acid to trihydroxyoestrin, and warming, an orange colouration with a green fluorescence is produced. Trihydroxyoestrin may be converted into ketohydroxyoestrin by heating with potassium acid sulphate at 180° to 200° and distilling in a vacuum.

The separation of trihydroxyoestrin and ketohydroxyoestrin from crude concentrates obtained from pregnancy urine may be effected by treatment with methyl alcohol (50 per cent.) and light petroleum; the alcoholic layer is separated and extracted with ether, and the residue obtained after evaporating the ethereal layer is treated with methyl alcohol (50 per cent.) and benzene. The benzene solution contains ketohydroxyoestrin, which can be purified by crystallisation. The alcohol contains trihydroxyoestrin, and is extracted with ether after acidification with hydrochloric acid. The ethereal solution is washed with sodium carbonate solution, and the trihydroxyoestrin extracted with sodium hydroxide solution, from which it is precipitated by the addition of hydrochloric acid, extracted with ether and purified by crystallisation.

Ketohydroxyoestrin is easily **soluble** in alcohol, acetone, chloroform, benzene and fixed oils; soluble with difficulty in ether, ethyl acetate and light petroleum; very slightly soluble in water (about 1 in 65,000).

Trihydroxyoestrin is only slightly soluble in ether, more soluble in alcohol, methyl alcohol, chloroform, acetone and fixed oils; completely soluble in potassium hydroxide solution and precipitated from this solution by carbon dioxide; insoluble in aqueous sodium carbonate solution.

Standard.—The potency of preparations of the oestrins is estimated by a biological method, and stated in units. The unit suggested for international use by the Permanent Commission on Biological Standardisation of the League of Nations Health Organisation is defined as the specific oestrus-producing activity in 0.1 gamma (0.0001 milligram) of the standard preparation, this quantity being approximately one-third of the original rat unit of activity. The standard preparation is a sample of the hydroxyketonic form of the hormone normally obtained from urine of pregnancy, and kept at the National Institute for Medical Research, London. The assay of a preparation of oestrin is conducted by comparing its specific oestrus-producing activity with that of the standard, under strictly identical conditions, by a method capable of yielding results with an error not greater than ± 20 per cent. The oestrus-producing activity is the power of producing in adult female rats or mice, completely deprived of their ovaries, the cellular changes in the vaginal secretion characteristic of normal oestrus. At least twenty animals should be used for each dose of the standard and of the preparation under test.

Action and Uses.—When injected into a female animal, ketohydroxy-oestrin produces all those changes which facilitate the fertilisation of an ovum. The vaginal canal enlarges, and an epithelial lining is formed, the uterus enlarges and becomes distended with fluid, in which the spermatozoa from the male have the best opportunity of approaching an ovum from the female; ovulation takes place, and ripe ova are discharged from the surface of the ovary to enter the uterus. The action of trihydroxyoestrin is qualitatively the same as that of ketohydroxyoestrin, but quantitatively it is less effective. While ketohydroxyoestrin is relatively ineffective when given by the mouth, trihydroxyoestrin is from one-half to one-third as active by mouth as by hypodermic injection.

The use of oestrin in therapeutics and a satisfactory scale of dosage have not yet been definitely established. Calculations on a weight basis from the doses effective in small animals indicate that in order to obtain appreciable action in the human subject the dose must be extremely large. There is clinical evidence, however, that repeated injections of 150 to 300 units will induce menstruation in patients suffering from amenorrhœa, and are of some value in the treatment of chronic mastitis, and of the vasomotor symptoms of the menopause. There is no evidence that it is of value in human beings for the induction of labour.

The oestrins are **administered** by hypodermic or intramuscular injection. Injected in the form of aqueous solution, the active principle exerts only a transient effect, as it appears to be excreted in the urine very rapidly. Solutions in oil exert a more prolonged action, and owing to the greater solubility of oestrin in oil, they make possible the use of larger doses. Trihydroxyoestrin may be administered by the mouth. Solutions of oestrin for **injection** may be sterilised by tyndallisation or by filtration.

SYNTHETIC OESTRUS-PRODUCING COMPOUNDS.—A number of synthetic condensed ring compounds show a well-marked oestrus-producing action when injected into ovariectomised rats. Among the more potent of these are:—9 : 10-dihydroxy-9 : 10-di-*n*-butyl-9 : 10-dihydro-1 : 2 : 5 : 6-dibenzanthracene, 1-keto-1 : 2 : 3 : 4-tetrahydrophenanthrene, 5 : 6-cyclopenteno-1 : 2-benzanthracene, and 1 : 2-benzpyrene. The last two of these are also powerful carcinogenic agents.

OLEUM ABIETIS

(Ol. Abiet.)

Oil of Siberian Fir

Synonyms—Oil of Pine; Oleum Pini.

Oil of Siberian fir is obtained by distillation from the fresh leaves of *Abies sibirica* Ledeb. (Fam. Coniferæ), chiefly in North-East Russia.

It occurs as a colourless or pale yellow liquid, with an agreeable, characteristic, pine-like odour and a pungent taste. Oil of Siberian fir **contains** about 40 per cent. of esters, calculated as bornyl acetate, and also pinene, camphene, dipentene and phellandrene. It should be **stored** in well-closed containers in a cool place and protected from light.

Standard, B.P.—Oil of Siberian fir contains not less than 35 per cent. w/w and not more than 45 per cent. w/w of esters, calculated as bornyl acetate, $C_{12}H_{20}O_2$. Specific gravity, 0.905 to 0.925. Optical rotation, -32° to -45° . Refractive index at 20° , 1.466 to 1.476. It is soluble in an equal volume of alcohol (90 per cent.; specific gravity, 0.8334 to 0.8340).

Action and Uses.—Oil of Siberian fir has properties closely resembling those of oil of pumilio pine; the latter is sometimes preferred on account of its more pleasant odour.

OLEUM AJOWAN

(Ol. Ajowan)

Ajowan Oil

Synonym—Ptychotis Oil.

Ajowan oil is obtained by distillation from the fruits of *Trachyspermum Ammi* (Linn.) Sprague, which is indigenous to and cultivated in India; the fruit yields from 3 to 4 per cent. of the oil. It occurs as an almost colourless or brownish liquid, having the odour of thyme and a sharp, burning taste. Ajowan oil **contains** thymol, which can be crystallised from the oil. Complete separation may be effected by shaking with solution of sodium hydroxide to form the sodium compound, from which thymol is liberated by means of hydrochloric acid, and may be recrystallised finally from alcohol. The remainder of the oil consists of paracymene, $C_{10}H_{14}$, boiling at 175° , and a terpene boiling at 172° , with traces of pinene and dipentene, the mixture being known commercially as "thymene."

Soluble in alcohol (90 per cent.) (1 in 4).

Standard.—Ajowan oil contains not less than 40 per cent. v/v of thymol, $C_{10}H_{14}O$. Specific gravity, 0.910 to 0.930. Optical rotation, 0° to $+2^\circ$. Refractive index at 20° , 1.485 to 1.510.

Assay.—Proceed by the method of the British Pharmacopœia for the determination of eugenol in Oleum Caryophylli; the unabsorbed oil measures not more than 6 millilitres, corresponding to not less than 40 per cent. v/v of thymol.

Action and Uses.—Ajowan oil is employed in India as an antiseptic and aromatic carminative. Its action and uses are similar to those of thymol.

Dose.—0.03 to 0.2 millilitre ($\frac{1}{2}$ to 3 minims)

OLEUM AMYGDALÆ

(Ol. Amygdal.)

Almond Oil

Almond oil is the fixed oil obtained by pressure from bitter or sweet almond, the greater part being obtained from bitter almond. It occurs as a clear, pale yellow oil, with a slight characteristic odour and a bland, nutty taste. Almond oil **contains** olein, with a small proportion of the glycerides of linolic and other acids; it contains no stearin.

Slightly **soluble** in alcohol (90 per cent.), ether (1 in 2.25); miscible in all proportions with chloroform, benzene and light petroleum.

Standard, B.P.—Almond oil has a specific gravity of 0.915 to 0.920. Refractive index at 40°, 1.4624 to 1.4650. Acid value, not more than 4.0. Saponification value, 188 to 196. Iodine value, 95 to 100. It remains clear after exposure to a temperature of -10° for three hours, and does not congeal until cooled to about -18° . It complies also with tests for the absence of apricot-kernel oil and peach-kernel oil, cottonseed oil, sesame oil, and arachis oil.

Action and Uses.—Almond oil is nutritive, demulcent and laxative. The oil is applied externally as an emollient for chapped hands and slight excoriations. It may be **administered** in the form of an emulsion. Almond oil is usually preferred in the preparation of cold creams and similar toilet articles. It is the basis of some brillianines, and is added to lotions for the hair. Sterilised almond oil is used for lubricating catheters, and as a vehicle in the preparation of injections. It may be sterilised by heating at 150° for one hour.

Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Preparation

Lotio Olei Amygdalæ Ammoniata, B.P.C.—(Lot. Ol. Amygdal. Ammon.)—Ammoniated Almond Oil Lotion. *Syn.*—Erasmus Wilson's Hair Lotion; Lotio Crinalis. Almond oil, 1 in 8, with strong solution of ammonia, oil of rosemary, alcohol (90 per cent.) and honey water.

OLEUM AMYGDALÆ AMARÆ

(Ol. Amygdal. Amar.)

Oil of Bitter Almond

Synonym—Oleum Amygdalæ Essentiale.

Oil of bitter almond is obtained by distilling moistened bitter almond cake, and also from the cake of the seeds of the apricot and peach. The oil does not pre-exist in the almond cake, but is formed by the interaction of amygdalin and emulsin, the products of the reaction being benzaldehyde, benzaldehyde-cyanhydrin, hydrocyanic acid and dextrose. Hydrocyanic acid, free and combined, may be present in the natural oil to the extent of 3.5 to 10.0 per cent., but the product is suitably adjusted to contain from 2 to 4 per cent. Oil of bitter almond

occurs as a colourless liquid, having a characteristic odour; it is optically inactive. On exposure to air it is oxidised, and gradually deposits benzoic acid as a solid crystalline mass. This change takes place more readily in the oil freed from hydrocyanic acid, which acts as a preservative. The presence of chlorine indicates contamination with, or substitution by, synthetically prepared benzaldehyde. The absence of chlorides is not an infallible indication of its purity, since benzaldehyde free from chlorine is available.

Sparingly **soluble** in water (1 in 300); soluble in all proportions of alcohol, ether, fixed and volatile oils.

Standard.—Oil of bitter almond, determined by the method for Benzaldehydum, contains not less than 85 per cent. w/w of $C_6H_5 \cdot CHO$, and the equivalent of not less than 2 per cent. and not more than 4 per cent. w/w of HCN. Specific gravity, 1.055 to 1.065. Refractive index at 20° , 1.534 to 1.542. It complies with the limit test for chlorinated compounds in Benzaldehydum. Weigh accurately 5 grammes of the oil and dissolve in neutral alcohol (90 per cent.); the solution requires not more than 1.6 millilitres of N/2 alcoholic potassium hydroxide for neutralisation to phenolphthalein (limit of benzoic acid). Add 0.5 millilitre to 5 millilitres of alcohol, add a small quantity of zinc powder and 2 millilitres of acetic acid, and boil the mixture for about ten seconds; no odour of phenyl isocyanide develops after making the liquid alkaline with sodium hydroxide solution and heating with a few drops of chloroform (absence of nitrobenzene).

Assay.—For hydrocyanic acid. Dissolve about 1 gramme, accurately weighed, in 25 millilitres of alcohol (90 per cent.), add 1 millilitre of potassium iodide solution and 1 millilitre of dilute ammonia solution, and titrate with N/10 silver nitrate to a permanent opalescence; 1 millilitre of N/10 silver nitrate is equivalent to 0.0054 gramme of HCN.

Action and Uses.—Oil of bitter almond is employed as a flavouring agent in confectionery. It is more stable than the oil freed from hydrocyanic acid, and for this reason it is preferred, but it must be used with caution. In cases of **poisoning** by oil of bitter almond, the antidotes are those for Acidum Hydrocyanicum Dilutum.

Dose.—0.016 to 0.06 millilitre ($\frac{1}{4}$ to 1 minim).

OLEUM AMYGDALÆ AMARÆ SINE ACIDO HYDROCYANICO

(Ol. Amygdal. Amar. s. Acid. Hydrocyan.)

Oil of Bitter Almond without Hydrocyanic Acid

Synonyms.—Oleum Amygdalæ Amaræ sine Acido Prussico; Oleum Amygdalæ Amaræ (s.A.P.).

Oil of bitter almond without hydrocyanic acid is oil of bitter almond from which the hydrocyanic acid has been removed by shaking with

milk of lime and ferrous sulphate, whereby hydrocyanic acid is precipitated as calcium ferrocyanide, and redistilling the oil with steam. It is a colourless liquid, with a characteristic odour, and is optically inactive. On exposure to air it is rapidly oxidised, and benzoic acid is deposited as a crystalline mass. This change takes place more rapidly in the oil freed from hydrocyanic acid than in the natural oil. It should be **stored** in small, closely-stoppered bottles and protected from light and air.

Sparingly **soluble** in water (1 in 300); soluble in alcohol, ether, fixed and volatile oils.

Standard.—Oil of bitter almond without hydrocyanic acid, determined by the method for Benzaldehydum, contains not less than 95 per cent. w/w of $C_6H_5 \cdot CHO$. Specific gravity, 1.048 to 1.052. Refractive index at 20°, 1.540 to 1.545. It complies with the limit tests for hydrocyanic acid and chlorinated compounds in Benzaldehydum, and with the limit tests for benzoic acid and nitrobenzene in Oleum Amygdalæ Amaræ.

Action and Uses.—Oil of bitter almond without hydrocyanic acid is employed as a flavouring agent for emulsions, and for use in domestic culinary operations. It should not be confused with Oleum Amygdalæ Amaræ, which contains hydrocyanic acid and which is often preferred by confectioners.

Dose.—0.016 to 0.06 millilitre ($\frac{1}{4}$ to 1 minim).

Preparation

Spiritus Amygdalæ Amaræ, B.P.C.—(Sp. Amygdal. Amar.)—Spirit of Bitter Almond. *Syn.*—Essence of Bitter Almonds. Oil of bitter almond without hydrocyanic acid, 1 in 16, in alcohol (90 per cent.).

OLEUM ANETHI

(Ol. Aneth.)

Oil of Dill

Oil of dill is obtained by distillation from dill fruit. It occurs as a colourless or pale yellow liquid, becoming darker on keeping, having a characteristic, aromatic odour and a taste which is sweet and aromatic at first, but afterwards pungent. It closely resembles oil of caraway, but contains less carvone. Oil of dill **contains** about 50 per cent. of carvone, $C_{10}H_{14}O$; it also contains limonene, phellandrene and other terpenes, and a paraffin hydrocarbon. It does not contain anethole. East Indian dill oil, from the fruits of *Peucedanum Sowa* Kurz., is distinguished by its higher specific gravity (0.948 to 0.975) lower optical rotation ($+41^\circ$ to $+47^\circ$), and by its containing dill apiol, which boils at 285° and sinks in water. Genuine oil of dill contains no constituent boiling at so high a temperature, and no portion of the distillate

sinks in water. It should be **stored** in well-closed containers in a cool place and protected from light.

Standard, B.P.—Oil of dill contains not less than 43 per cent. and not more than 63 per cent. w/w of carvone, $C_{10}H_{14}O$. Specific gravity, 0.900 to 0.915. Optical rotation, $+70^{\circ}$ to $+80^{\circ}$. Refractive index at 20° , 1.481 to 1.492. It is soluble in an equal volume of alcohol (90 per cent.; specific gravity, 0.8334 to 0.8340), and in 10 volumes of alcohol (80 per cent.; specific gravity, 0.8634 to 0.8640).

Action and Uses.—Oil of dill is employed as an aromatic carminative, especially in the flatulence of infants.

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

OLEUM ANISI

(Ol. Anis.)

Oil of Anise

Synonym—Oil of Aniseed.

Oil of anise is obtained by distillation from anise or from star anise, the greater part of the commercial product being obtained from the latter. It occurs as a colourless or pale yellow, highly-refractive liquid, with a characteristic odour and a sweet, aromatic taste. On cooling, it solidifies to a white, crystalline mass, but it can be cooled considerably below its freezing-point without becoming solid if undisturbed, but slight agitation, or the introduction of a crystal of anethole, causes immediate solidification. Exposure to air causes polymerisation, and some oxidation also takes place with formation of anisic aldehyde, $C_8H_8O_2$, and anisic acid. Oil of anise **contains** about 80 to 90 per cent. of anethole, $C_{10}H_{12}O$, to which the characteristic properties of the oil are due. Anethole occurs in the form of white, crystalline laminæ, melting at 21° or as a colourless liquid which boils at 232° . The oil contains also methyl chavicol, an isomeride of anethole and resembling it in odour but not in taste. These two constituents, together with traces of the oxidation products, anisic aldehyde and anisic acid, are the only constituents of proved identity in the oil obtained from anise fruits. In star anise oil, however, *d*-pinene, *l*-phellandrene, the ethyl ether of hydroquinone, and probably safrole, also occur. Oil of anise should be **stored** in well-closed containers, in a cool place and protected from light. If the oil has solidified, it should be melted and mixed before use.

Standard, B.P.—Oil of anise has a specific gravity ($20^{\circ}/15.5^{\circ}$) of 0.980 to 0.994. Optical rotation, -2° to $+1^{\circ}$. Refractive index at 20° , 1.553 to 1.560. Freezing-point, not below 15° . Melting-point, not below 17° . It is soluble in three volumes of alcohol (90 per cent.; specific gravity, 0.8334 to 0.8340), the solution showing not more than a slight opalescence. It complies also with a limit test for lead.

Action and Uses.—Oil of anise is employed as an aromatic carminative to relieve flatulence. It is a mild expectorant and is an ingredient of cough lozenges, often in combination with liquorice. The oil may be **administered** on sugar, or as *Spiritus Anisi* or *Elixir Anisi*. As an antiseptic and flavouring agent, it is sometimes combined with the oils of sweet birch and peppermint in aromatic mouth-washes and dentifrices. It is also used in the compounding of liqueurs.

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

ALDEHYDUM ANISICUM.—Anisic aldehyde, aubepine, or artificial hawthorn, $C_6H_4(OCH_3) \cdot CHO$, may be obtained from oil of anise, or synthetically. It occurs as a colourless or slightly yellowish liquid, having a specific gravity of about 1.127 and a boiling-point of 246° . In combination with sodium pyrosulphite it is known as "crystallised aubepine." Anisic aldehyde is used in perfumery.

Preparations

Elixir Anisi, B.P.C.—(*Elix. Anis.*)—Elixir of Anise. Oil of anise, about 1 in 300, with oil of fennel, oil of bitter almond without hydrocyanic acid, alcohol (90 per cent.), syrup and distilled water. **Dose.**—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Spiritus Anisi, B.P.C.—(*Sp. Anis.*)—Spirit of Anise. Oil of anise, 1 in 10, in alcohol (90 per cent.). **Dose.**—0.3 to 1.2 millilitres (5 to 20 minims).

This spirit was included in the British Pharmacopœia, 1914.

OLEUM ANTHEMIDIS

(*Ol. Anthem.*)

Oil of Chamomile

Oil of chamomile is obtained by distillation from the recently dried flowers of *Anthemis nobilis* Linn. It occurs, when freshly distilled, as a blue liquid, becoming greenish and brownish-yellow under the influence of air and light, and having a strong, but pleasant, aromatic odour and a burning taste. It has a faintly acid reaction. The oil from the German chamomile, *Matricaria Chamomilla* Linn., has a specific gravity of about 0.917 to 0.957, and is much inferior in odour value. Oil of chamomile **contains** esters of angelic and tiglic acids (two isomeric acids of the formula $C_5H_8O_2$) with butyl and amyl alcohols, and butyric acid; it also contains an alcohol, anthemol, $C_{10}H_{16}O$, and a hydrocarbon, anthemene, $C_{18}H_{36}$, which forms crystalline needles melting at 63° . The blue colouration of the freshly-distilled oil is due to the presence of azulene, which can be extracted by strong mineral acids.

Standard.—Oil of chamomile forms a clear solution with 6 volumes of alcohol (70 per cent.; specific gravity, 0.8896 to 0.8901). Specific gravity, 0.905 to 0.915. Refractive index at 20° , 1.442 to 1.448. Acid value, 1.5 to 14.0. Saponification value, 260 to 296.

Action and Uses.—Oil of chamomile is employed as an aromatic carminative.

Dose.—0.03 to 0.2 millilitre ($\frac{1}{2}$ to 3 minims).

OLEUM ARACHIS

(Ol. Arach.)

Arachis Oil

Synonyms—Nut Oil; Oleum Nucis; Ground-nut Oil; Pea-nut Oil.

Arachis oil is obtained by expression, without heat, from the seeds of *Arachis hypogaea* Linn., a native of Brazil, and cultivated in West Africa, India, China and America. The seeds contain about 40 to 45 per cent. of the fixed oil. It occurs as a pale yellow liquid, with a faint, nutty odour and a bland, nutty taste. It becomes turbid when cooled to about 3° and solidifies at -5°. On exposure to the air, the oil thickens very slowly and becomes rancid. Bleached arachis oil is manufactured in France; it is nearly colourless and almost tasteless. Arachis oil **consists** chiefly of the glyceride of oleic acid, together with glycerides of arachidic, hypogæic, lignoceric and linolic acids, while the "stearine," which separates at low temperatures, contains the glyceride of arachidic acid. The oil contains an approximately constant proportion, about 4.8 per cent., of arachidic and lignoceric acids. The abnormally low solubility in alcohol (70 per cent.) of arachidic acid forms the basis of the usual test for arachis oil.

Slightly **soluble** in alcohol (90 per cent.); miscible with ether, chloroform and light petroleum.

Standard, B.P.—Arachis oil has a specific gravity of 0.916 to 0.920. Refractive index at 40°, 1.4625 to 1.4645. Acid value, not more than 4. Saponification value, 188 to 196. Iodine value, 85 to 99. It complies also with tests for the absence of cottonseed oil, sesame oil, and other vegetable oils.

Action and Uses.—Arachis oil has properties similar to those of olive oil and may be prescribed in place of it. It may be used in India and in the Eastern, African, Australasian and North American divisions of the Empire as a substitute for olive oil in making ointments, liniments, plasters and soaps for which olive oil is directed to be used. In the form of an emulsion it is used for feeding children. Arachis oil may be sterilised by heating at 150° for one hour.

Dose. 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Preparations

Emulsio Olei Arachis, B.P.C.—(Emuls. Ol. Arach.)—Emulsion of Arachis Oil.

Syn.—Marylebone Cream (Improved). Each fluid drachm contains about $\frac{1}{2}$ fluid drachm of arachis oil and solution of irradiated ergosterol equivalent to about 300 units of antirachitic activity. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Oleum Lubricans, B.P.C.—(Ol. Lubric.)—Lubricant Oil. *Syn.*—Lund's Oil; Catheter Oil. Phenol, 5 per cent. w/v, in castor oil and arachis oil.

OLEUM AURANTII

(Ol. Aurant.)

Oil of Orange*Synonym*—Essence of Orange.

Oil of orange is obtained by mechanical means from the fresh peel of the sweet orange, *Citrus sinensis* (Linn.) Osbeck (oil of sweet orange), and also the bitter orange, *Citrus Aurantium* Linn. subsp. *amara* Engl. (oil of bitter orange), chiefly in Calabria and Sicily, but also in the West Indies and Africa. By far the greater part of the oil of commerce is obtained from the sweet orange, but chemically the two oils are practically identical. It is possible, however, to distinguish them by their odour and taste. Oil of orange occurs as a yellow to yellowish-brown liquid, having the characteristic odour of orange, and a mild, aromatic taste, oil of bitter orange being bitter. It deteriorates on keeping, acquiring a disagreeable, terebinthinate taste. The addition of 10 per cent. of dehydrated alcohol to the fresh oil prevents this. It has a neutral reaction. The purity of the oil is best judged by the rotation and odour. Distilled oil of orange is an inferior article, the effect of heat and steam being detrimental to the oxygenated compounds, which are of a very delicate nature. Californian and Spanish oils also occur in commerce; they are usually of a dark colour, and leave a deep orange stain on paper. Oil of orange **contains** at least 90 per cent. of the terpene, *d*-limonene, $C_{10}H_{16}$. Other constituents are decyl aldehyde, the methyl ester of anthranilic acid and a stearoptene of which little is known. Traces of linalol and terpineol have also been found.

Soluble in alcohol (1 in 7), in all proportions of dehydrated alcohol, but not always with formation of bright solutions, on account of the presence of waxy, non-volatile substances.

Standard.—Oil of orange leaves on evaporation not less than 2 per cent. and not more than 4 per cent. w/w of residue. Specific gravity, (oil of sweet orange) 0.848 to 0.852, (oil of bitter orange) 0.852 to 0.856. Optical rotation, (oil of sweet orange) $+95^{\circ}$ to $+99^{\circ}$, (oil of bitter orange) $+88^{\circ}$ to $+96^{\circ}$. Refractive index at 20° , (oil of sweet orange) 1.472 to 1.474, (oil of bitter orange) 1.472 to 1.475. When distilled, the first 10 per cent. of the distillate has an optical rotation the same as, or only slightly lower than, the original oil.

Uses.—Oil of orange is employed in perfumery and in the form of Elixir Aromaticum as a flavouring agent for mixtures.

Dose.—0.03 to 0.2 millilitre ($\frac{1}{2}$ to 3 minims).

Preparation

Elixir Aromaticum, B.P.C.—(Elix. Aromat.)—Aromatic Elixir. *Syn.*—Elixir Aurantii; Elixir Aurantii Compositum. Oil of orange, 1 in 400, with oils of lemon, coriander and anise, alcohol (90 per cent.), syrup and distilled water. **Dose.**—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

OLEUM BERGAMOTTÆ

(Ol. Bergam.)

Oil of Bergamot*Synonym*—Essence of Bergamot.

Oil of bergamot is obtained by expression from the fresh peel of the fruit of *Citrus Aurantium* Linn. subsp. *bergamia* Engl., cultivated mostly in Southern Calabria. It occurs as a greenish or brownish-yellow liquid, having a pleasant odour and a bitter and very unpleasant taste. Adulteration of oil of bergamot is very easily detected by changes in the physical constants. Oil of turpentine diminishes the specific gravity; fatty oils, cedar wood oil, and gurgun oil increase it; lemon and orange oils increase the rotation and decrease the specific gravity, ester content and solubility. Fatty oils decrease the solubility, and increase the amount of residue on evaporation. Oil of bergamot **contains** the ester, linalyl acetate, $C_{12}H_{20}O_2$, which is the chief source of the fragrance of the oil. In addition to this ester there is usually about 6 per cent. of free *l*-linalol, $C_{10}H_{18}O$, and *d*-limonene, dipentene, pinene, camphene, octylene, and acetic acid. The oil is sometimes rectified, but it suffers in consequence, the ester being partially decomposed. The oil, on keeping, deposits a crystalline magma of bergaptene, $C_{12}H_{18}O_4$, a non-volatile substance, which is inodorous at ordinary temperatures, but gives off aromatic vapours on heating and melts at about 188° .

Soluble in about one-half its volume of alcohol (90 per cent.), the solution not becoming turbid on the further addition of alcohol. Usually soluble also in twice its volume of alcohol (80 per cent. w/w; 85.5 per cent. v/v).

Standard.—Oil of bergamot, determined by the method of the British Pharmacopœia for the determination of esters in volatile oils, contains not less than 36 per cent. of esters, calculated as linalyl acetate, $C_{12}H_{20}O_2$. Specific gravity, 0.882 to 0.886. Optical rotation, $+12^{\circ}$ to $+24^{\circ}$. Refractive index at 20° , 1.464 to 1.467. Residue on evaporation, not less than 4 per cent. and not more than 6 per cent. w/w, the acid value of the residue being between 20 and 50, and the saponification value between 160 and 200. Place in a flask 1 gramme of the oil with 3 millilitres of a 10 per cent. w/v potassium hydroxide solution in dehydrated alcohol; attach an air condenser, heat on a water-bath for 1 minute and allow to cool; no cloudiness or crystalline precipitate is produced within one hour (absence of certain artificial esters). Make two determinations of the ester content, boiling for one hour and two hours respectively; the difference between the two results does not exceed 0.5 per cent. (absence of terpinyl acetate). Shake 10 millilitres of the oil in a separator with 10 millilitres of light petroleum, 2.5 millilitres of alcohol (90 per cent.) and 20 millilitres of water; filter the aqueous layer, neutralise with N/2 alcoholic potassium hydroxide solution and saponify

for one hour with 10 millilitres of N/2 alcoholic potassium hydroxide; not more than 0.2 millilitre is absorbed (absence of glyceryl acetate).

Uses.—Oil of bergamot is largely employed in perfumery, especially in oils and pomades for the hair.

LINALOLUM.—Linalol, or linalool, $C_{10}H_{18}O$, is an open-chain alcohol occurring free in essential oil of linaloe and, in the form of esters, in numerous essential oils. It is a colourless liquid with a sweet odour, having a specific gravity of about 0.870 to 0.880 and a boiling-point of about 198° . It is used in perfumery and for the manufacture of esters of linalol, which are also used in perfumery.

LINALYLIS ACETAS.—Linalyl acetate, $CH_3 \cdot COOC_{10}H_{17}$, is the principal odorous constituent of oil of bergamot and occurs also in oil of lavender and other oils. It is prepared by the esterification of linalol and occurs as a colourless oil with a powerful bergamot odour and a specific gravity of about 0.900 to 0.910. It is largely used in perfumery.

Preparation

Spiritus Coloniensis, B.P.C.—(Sp.Colon.)—Cologne Spirit. *Syn.*—Aqua Coloniensis. Oils of bergamot, lemon, neroli, rosemary and thyme, and triple orange-flower water, in alcohol (90 per cent.).

OLEUM BETULÆ

(Ol. Betul.)

Oil of Sweet Birch

Synonyms—Oil of Wintergreen; Oleum Gaultheriæ.

Oil of sweet birch was formerly obtained by distillation from the leaves of *Gaultheria procumbens* Linn., but is now distilled from the bark of *Betula lenta* Linn. It occurs as a colourless or yellowish liquid, having a sweetish, aromatic taste and a characteristic odour. The oil does not pre-exist in the bark of *Betula lenta*, but is formed by the interaction of the glycoside, gaultherin, and a ferment, betulase. To 0.5 millilitre of the oil add 0.5 millilitre of a 5 per cent. solution of vanillin in alcohol and 2 millilitres of alcohol, shake well, add 2 millilitres of sulphuric acid and again shake; a blood-red colour is produced. The oil **contains** methyl salicylate, $C_6H_4(OH) \cdot COOCH_3$, with about 1 per cent. of other bodies including an alcohol or ketone, and an ester, to the presence of which is due the characteristic odour by which oil of sweet birch is distinguished from methyl salicylate.

Standard.—Oil of sweet birch, determined by the method of the British Pharmacopœia for esters in volatile oils, contains not less than 98 per cent. w/w of esters, calculated as methyl salicylate, $C_8H_8O_3$. Specific gravity, 1.182 to 1.192. Optical rotation, $+0.5^{\circ}$ to -0.5° . Refractive index at 20° , 1.534 to 1.538.

Action and Uses.—Oil of sweet birch is sometimes given internally for acute rheumatism and sciatica. Applied to the skin the oil is readily absorbed; it may, however, give rise to an eruption and methyl salicylate

is therefore preferred for external application. It is an invaluable application for chronic rheumatic affections, fibrositis and lumbago. The oil is usually **administered** in capsules on account of its pungent taste.

Dose.—0·3 to 1 millilitre (5 to 15 minims).

OLEUM CADINUM

(Ol. Cadin.)

Oil of Cade

Synonym—Juniper Tar Oil.

Oil of cade is an empyreumatic, oily liquid obtained by the destructive distillation of the branches and wood of *Juniperus Oxycedrus* Linn., a tree common in the Mediterranean districts of Northern Africa, France and Spain. It occurs as a dark reddish-brown or nearly black, oily liquid, with an empyreumatic odour and an aromatic, bitter and acrid taste. If the oil is shaken with water and filtered, the filtrate is almost colourless and has a slightly acid reaction; it reduces ammoniacal silver nitrate solution and potassio-cupric tartrate solution, and gives a red colour on the addition of a very dilute solution of ferric chloride. Oil of cade is liable to adulteration with coal tar oil or wood tar oil, both of which contain furfurol and catechol. Furfurol may be detected by adding a few drops of aniline to the aqueous filtrate of the oil; if present, an immediate bright red colouration is produced, whereas with pure oil of cade the liquid is colourless, assuming a mahogany-brown tint when shaken with an acid. Catechol may be detected by the deep brown colouration it gives with potassium chromate or dichromate. Wood tar is also detected by the test for pine tar oil. Oil of cade **contains** a high percentage of cadinene, $C_{15}H_{24}$, a sesquiterpene widely distributed among the essential oils and forming a crystallisable dihydrochloride from which it may be regenerated by heating with aniline or sodium acetate and acetic acid. Cadinene has a specific gravity of about 0·918 at 20° and boils at 274° to 275°; on dissolving it in glacial acetic acid and adding a little sulphuric acid, a green colouration is produced which changes through blue to red.

Soluble in ether (1 in 3), and chloroform; partly soluble in cold alcohol (90 per cent.); almost entirely soluble in hot alcohol (90 per cent.); very slightly soluble in water.

Standard, B.P.—Oil of cade has a specific gravity of 0·975 to 1·010. Refractive index at 20°, 1·510 to 1·530. It complies also with a test for absence of pine tar oil.

Action and Uses.—Oil of cade is employed as a stimulant antiseptic in chronic skin diseases and as an ingredient of preparations for the scalp. Unguentum Olei Cadini is applied for psoriasis and eczema, and may be diluted with lard or soft paraffin, if necessary. It is better to

begin with weak preparations, 2 per cent. or less, and to increase the strength gradually, if necessary. Medicated soaps are prepared containing 5 to 10 per cent. of oil of cade.

Preparation

Unguentum Olei Cadini, B.P.C.—(Ung. Ol. Cadin.)—Oil of Cade Ointment. Oil of cade, 25 per cent., in yellow beeswax and yellow soft paraffin.

OLEUM CAJUPUTI

(Ol. Cajuput.)
